CHÂTELET (from Med. Lat. castella), the word, sometimes also written castellet, used in France for a building designed for the defence of an outwork or gate, sometimes of great strength or size, but distinguished from the château, or castle proper, in being purely defensive and not residential. In Paris, before the Revolution, this word was applied both to a particular building and to the jurisdiction of which it was the seat. This building, the original Châtele, had been first a castle defending the approach to the Cité. Tradition traced its existence back to Roman times, and in the 18th century one of the rooms in the great tower was still called the chambre de César. The jurisdiction was that of the provostship (prévôté) and viscountship of Paris, which was certainly of feudal origin, probably going back to the counts of Paris.

It was not till the time of Saint Louis that, with the appointment of Étienne Boileau, the provostship of Paris became a prévôté en garde, i.e. a public office no longer put up to sale. When the baillis (see Bailiff and Bailie) were created, the provost of Paris naturally discharged the duties and functions of a bailli, in which capacity he heard appeals from the seigniorial and inferior judges of the city and its neighbourhood, keeping, however, his title of provost. When under Henry II. certain bailliages became presidial jurisdictions (présidiaux), i.e. received to a certain extent the right of judging without appeal, the Châtele, the court of the provost of Paris, was made a presidial court, but without losing its former name. Finally, various tribunals peculiar to the city of Paris, i.e. courts exercising jurisdictions outside the common law or corresponding to certain cours d'exception which existed in the provinces, were united with the Châtele, of which they became divisions (chambres). Thus the lieutenant-general of police made it the seat of his jurisdiction, and the provost of the Ile de France, who had the same criminal jurisdiction as the provosts of the marshals of France in other provinces, sat there also. As to the personnel of the Châtele, it was originally the same as the bailliages, except that after the 14th century it had some special officials, the auditors and the examiners of inquests. Like the baillis, the provost had lieutenants who were deputies for him, and in addition gradually acquired a considerable body of ex officio councillors. This last staff, however, was not yet in existence at the end of the 14th century, for it is not mentioned in the Registre criminel du Châtele (1389–1392), published by the Société des Bibliophiles Français. In 1674 the whole personnel was doubled, at the time when the new Châtele was established side by side with the old, the two being soon amalgamated. On the eve of the Revolution it comprised, beside the provost whose office had become practically honorary, the lieutenant civil, who presided over the chambre de prévôté au parc civil or court of first instance; the lieutenant criminel, who presided over the criminal court; two lieutenants particuliers, who presided in turn over the chambre du présidial or court of appeal from the inferior jurisdictions; a juge auditeur; sixty-four councillors (conseillers); the procureur du roi, four avocats du roi, and eight substituts, i.e. deputies of the procureur (see PROCURATOR), beside a host of minor officials. The history of the Châtele under the Revolution may be briefly told: the Constituent Assembly empowered it to try cases of lèse-nation, and it was also before this court that was opened the inquiry following on the events of the 5th and 6th of August 1789. It was suppressed by the law of the 16th of August 1790, together with the other tribunals of the ancien régime.

(J. P. E.)

CHÂTELLERAULT, a town of western France, capital of an arrondissement in the department of Vienne, 10 m. N.N.E. of Poitiers on the Orleans railway between that town and Tours. Pop. (1906) 15,214. Châtellerault is situated on the right and eastern bank of the Vienne; it is connected with the suburb of Châteauineuf on the opposite side of the river by a stone bridge of the 16th and 17th centuries, guarded at the western extremity by massive towers. The manufacture of cutlery is carried on on a large scale in villages on the banks of the Clain, south of the town. Of the other industrial establishments the most important is the national small-arms factory, which was established in 1825 in Châteauineuf, and employs from 1500 to 5500 men. Châtellerault (or Châtelerault: Castellum Atralii) derives its name from a fortress built in the 10th century by Alraud, viscount of its territory. In 1515 it was made a duchy in favour of François de Bourbon, but it was not long after this date that it became reunited to the crown. In 1548 it was bestowed on James Hamilton, 2nd earl of Arran (see Hamilton).

CHATHAM, WILLIAM PITT, 1st Earl of (1708–1778), English statesman, was born at Westminster on the 15th of November 1708. He was the younger son of Robert Pitt of Boscnnoc, Cornwall, and grandson of Thomas Pitt (1653–1726), governor of Madras, who was known as “Diamond” Pitt, from the fact of his having sold a diamond of extraordinary size to the regent Orleans for something like £135,000. It was mainly by this fortunate transaction that the governor was enabled to raise his family, which was one of old standing, to a position of wealth and political influence. The latter he acquired by purchasing the burgage tenures of Old Sarum.

William Pitt was educated at Eton, and in January 1727 was entered as a gentleman commoner at Trinity College, Oxford. There is evidence that he was an extensively read, if not a minutely accurate classical scholar; and it is interesting to know that Demosthenes was his favourite author, and that he diligently cultivated the faculty of expression by the practice of translation and re-translation. An hereditary gout, from which
he had suffered even during his school-days, compelled him to leave the university without taking his degree, in order to travel abroad. He spent some time in France and Italy; but the disease proved intractable, and he continued subject to attacks of growing intensity at frequent intervals till the close of his life. In 1727 his father had died, and on his return home it was necessary for him, as the younger son, to choose a profession. Having chosen the army, he obtained through the interest of his friends a cornet's commission in the dragoons. But his military career was destined to be short. His elder brother Thomas having been returned at the general election of 1734 both for Oakhampton and for Old Sarum, and having preferred to sit for the former, the family borough fell to the younger brother by the sort of natural right usually recognized in such cases. Accordingly, in February 1735, William Pitt entered parliament as member for Old Sarum. Attaching himself at once to the formidable band of discontented Whigs known as the Patriots, whom Walpole's love of exclusive power had forced into opposition under Pulteney, he became in a very short time one of its most prominent members. His maiden speech was delivered in April 1736, in the debate on the congratulatory address to the king on the marriage of the prince of Wales. The occasion was one of compliment, and there is nothing striking in the speech as reported; but it served to gain for him the attention of the house when the series of stormy debates, he conducted afterwards during the session, proved of a party character. So obnoxious did he become as a critic of the government, that Walpole thought fit to punish him by procuring his dismissal from the army. Some years later he had occasion vigorously to denounce the system of cashiering officers for political differences, but with characteristic loftiness of spirit he disdained to make any reference to his own case. The loss of his commission was soon made up to him. The heir to the throne, as was usually the case in the house of Hanover, if not in reigning families generally, was the patron of the opposition, and the ex-cornet became groom of the bed-chamber to the prince of Wales. In this new position his hostility to the government did not, as may be supposed, in any degree relax. He had all the natural gifts an orator could desire—a commanding presence, a graceful though somewhat theatrical bearing, an eye of piercing brightness, and a voice of the utmost flexibility. His style, if occasionally somewhat turgid, was elevated and passionate, and it always bore the impress of that intensity of conviction which is the most powerful instrument a speaker can have to sway the convictions of an audience. It was natural, therefore, that in the series of stormy debates, he conducted afterwards during the session, that ended in the downfall of Walpole, his eloquence should have been one of the strongest of the forces that combined to bring about the final result. Specially effective, according to contemporary testimony, were his speeches against the Hanoverian subsidies, against the Spanish convention in 1739, and in favour of the motion in 1742 for an investigation into the last ten years of Walpole's administration. It must be borne in mind that the reports of these speeches which have come down to us were made from hearsay, or at best from recollection, and are necessarily therefore most imperfect. The best-known specimen of Pitt's eloquence, his reply to the sneers of Horatio Walpole at his youth and declamatory manner, which has found a place in some handbooks of elocution, is evidently, in form at least, the work, not of Pitt, but of Dr Johnson, who furnished the report to the Gentleman's Magazine. Probably Pitt did say something of the kind attributed to him, though even this is by no means certain in view of Johnson's repentant admission that he had often invented not merely the form, but the substance of entire debates.

In 1742 Walpole was at last forced to succumb to the long-continued attacks of opposition, and was succeeded as prime minister by the earl of Wilmington, though the real power in the new government was divided between Carteret and the Pelhams. Pitt's conduct on the change of administration was open to grave censure. The relentless vindictiveness with which he insisted on the prosecution of Walpole, and supported the bill of indemnity to witnesses against the fallen minister, was in itself not magnuminous; but it appears positively unworthy when it is known that a short time before Pitt had offered no certain conditions, to use all his influence in the other direction. Possibly he was embittered at the time by the fact that, owing to the strong personal dislike of the king, caused chiefly by the contemptuous tone in which he had spoken of Hanover, he did not by obtaining a place in the new ministry reap the fruits of the victory to which he had so largely contributed. The so-called "broad-bottom" administration formed by the Pelhams in 1744, after the dismissal of Carteret, though it included several of those with whom he had been accustomed to act, did not at first include Pitt himself even in a subordinate office. Before the obstacle to his admission was overcome, he had received a remarkable accession to his private fortune. The eccentric duchess of Marlborough, dying in 1744, at the age of ninety, left him a legacy of £10,000 as an "acknowledgment of the noble defence he had made for the support of the laws of England and to prevent the ruin of his country." As her hatred was known to be at least as strong as her love, the legacy was probably as much a mark of her detestation of Walpole as of her admiration of Pitt. It may be mentioned here, though it does not come in chronological order, that Pitt was a second time the object of a form of acknowledgment of public virtue which few statesmen have had the fortune to receive even once. About twenty years after the Marlborough legacy, Sir William Pynsent, a Somersetshire landowner, who had been personally quite unknown, left him his entire estate, worth about three thousand a year, in testimony of approval of his political career.

It was with no very good grace that the king at length consented to give Pitt a place in the government, although the latter did all he could to ingratiate himself at court, by changing his tone on the questions on which he had made himself offensive. To force the matter, the Pelhams had to resign expressly on the question whether he should be admitted or not, and it was only after all other arrangements had proved impracticable, that they were reinstated with the obnoxious politician as vice-treasurer of Ireland. This was in February 1746. In May of the same year he was promoted to the more important and lucrative office of paymaster-general, which gave him a place in the privy council, though not in the cabinet. Here he had an opportunity of displaying his public spirit and integrity in a way that deeply impressed both the king and the country. It had been the usual practice of previous paymasters to appropriate to themselves the interest of all money lying in their hands by way of advance, and also to accept a commission of ½% on all foreign subsidies. Although there was a strong public sentiment against the practice, Pitt always refused to be fettered by it. All the money always lodged with him in the Bank of England until required, and all subsidies were paid over without deduction, even though it was pressed upon him, so that he did not draw a shilling from his office beyond the salary legally attaching to it. Conduct like this, though obviously disinterested, did not go without immediate and ample reward, in the public confidence which it created, and which formed the mainspring of Pitt's power as a statesman.

The administration formed in 1746 lasted without material change till 1754. It would appear from his published correspondence that Pitt had a greater influence in shaping its policy than his comparatively subordinate position would in itself have entitled him to. His conduct in supporting measures, such as the Spanish treaty and the continental subsidies, which he had violently denounced when in opposition, had been much criticized; but within certain limits, not indeed very well defined, inconsistency has never been counted a vice in an English statesman. The times change, and he is not blamed for changing with the times. Pitt in office, looking back on the commencement of his public life, might have used the plea, "A good deal has happened since then, at least as justly as some others have had. Allowance must always be made for the restraints and responsibilities of office. In Pitt's case, too, it is to be borne in mind that the opposition with which he had acted gradually dwindled away, and that it ceased to have any organized existence after the death of the prince of Wales in 1751. Then in regard to the important question with Spain as to the right of search,
Pitt has disarmed criticism by acknowledging that the course he followed during Walpole's administration was indefensible. All the weight being given to these various considerations, it must be admitted, nevertheless, that Pitt did overset the limits within which inconsistency is usually regarded as venial. His one great object was first to gain office, and then to make his tenure of office secure by conciliating the favour of the king. The entire revolution which much of his policy underwent in order to effect this object bears too close a resemblance to the sudden and inexplicable changes of front habitual to placemen of the Tadpole stamp to be altogether pleasant to contemplate in a politician of pure aims and lofty ambition. Humiliating is not too strong a term to apply to a letter in which he expresses his desire to "efface the past by every action of his life," in order that he may stand well with the king.

In 1754 Henry Pelham died, and was succeeded at the head of affairs by his brother, the duke of Newcastle. To Pitt the change brought no advancement, and he had thus an opportunity of testing the truth of the description of his chief given by Sir Robert Walpole; "His name is treason." But there was for a time no open breach. Pitt continued at his post, and at the general election which took place during the year he even accepted a nomination for the duke's pocket borough of Aldborough. He had sat for Seaford since 1747. When parliament met, however, he was not long in showing the state of his feelings. Ignoring Sir Thomas Robinson, the political nobody to whom Newcastle had entrusted the management of the Commons, he made frequent and vehement attacks on Newcastle himself, though still continuing to serve under him. In this strange state matters continued for about a year. At length, just after the meeting of parliament in November 1751, Pitt was dismissed from office, having on the debate on the address spoken at great length against a new system of continental subsidies, proposed by the government of which he was a member. Fox, who had just before been appointed secretary of state, retained his place, and though the two men continued to be of the same party, and afterwards served again in the same government, there was henceforward a rivalry between them, which makes the celebrated opposition of their illustrious sons seem like an inherited quarrel.

Another year had scarcely passed when Pitt was again in power. The inherent weakness of the government, the vigour and eloquence of his opposition, and a series of military disasters abroad combined to raise a public feeling of indignation which could not be withstood, and in December 1756 Pitt, who now sat for Okehampton, became secretary of state, and leader of the Commons under the premiership of the duke of Devonshire. He had made it a condition of his joining any administration that Newcastle should be excluded from it, thus showing a resentment which, though natural enough, proved fatal to the lengthened existence of his government. With the king unfriendly, and Newcastle, whose corrupt influence was still dominant in the Commons, estranged, it was impossible to carry on a government by the aid of public opinion alone, however emphatically that might have declared itself on his side. In April 1757, accordingly, he found himself again dismissed from office on a charge brought against him by his favourite minister's policy. But the power that was insufficient to keep him in office was strong enough to make any arrangement that excluded him impracticable. The public voice spoke in a way that was not to be mistaken. Probably no English minister ever received in so short a time so many proofs of the confidence and admiration of the public, the capital and all the chief towns voting him addresses and the freedom of their corporations. From the political deadlock that ensued relief could only be had by an arrangement between Newcastle and Pitt. After some weeks' negotiation, in the course of which the firmness and moderation of "the Great Commoner," as he had come to be called, contrasted favourably with the characteristic tartnesses of the crafty peer, matters were settled on such a basis that, while Newcastle was the nominal, Pitt was the virtual head of the government. On his acceptance of office he was chosen member for Bath.

This celebrated administration was formed in June 1757, and continued in power till 1761. During the four years of its existence it has been usual to say that the biography of Pitt is the history of England, so thoroughly was he identified with the great events which make this period, in so far as the external relations of the country are concerned, one of the most glorious in her annals. A detailed account of these events belongs to history; all that is needed in a biography is to point out the extent to which Pitt's personal influence may really be traced in them. It is scarcely too much to say that, in the general opinion of his contemporaries, the whole glory of these years was due to his single genius; his alone was the mind that planned, and his the spirit that animated the brilliant achievements of the British arms in all the four quarters of the globe. Posternity, indeed, has been able to recognize more fully the independent genius of those who carried out his purposes. The heroism of Wolfe would have been irrepressible, Clive would have proved himself "a heaven-born general," and Frederick the Great would have written his name in history as one of the most skilful strategists the world has known, whoever had held the seals of office in 1755. Pitt's relation to them was such as to entitle him to a large share in the credit of their deeds. It was his discernment that selected Wolfe to lead the attack on Quebec, and gave him the opportunity of dying a victor on the heights of Abraham. He had personally less to do with the successes in India than with the other great enterprises that shed an undying lustre on his administration; but his generous praise in parliament stimulated the genius of Clive, and the forces that acted at the close of the struggle were animated by his indomitable spirit. Pitt, the first real Imperialist in modern English history, was the directing mind in the expansion of his country, and with him the beginning of empire is rightly associated. The Seven Years' War might well, moreover, have been another Thirty Years' War if Pitt had not furnished Frederick with an annual subsidy of £700,000, and in addition relieved him of the task of defending western Germany against France.

Contemporary opinion was, of course, incompetent to estimate the permanent results gained for the country by the brilliant foreign policy of Pitt. It has long been generally agreed that by several of his most costly expeditions nothing was really won but glory. It has even been said that the only permanent acquisition that England owed directly to him was her Canadian dominion; and, strictly speaking, this is true, it being admitted that the campaign by which the Indian empire was virtually won was not planned by him, though brought to a successful issue during his ministry. But material aggrandizement, though the only tangible, is not the only real or lasting effect of a war policy. More may be gained by crushing a formidable rival than by conquering a province. The loss of her Canadian possessions was only one of a series of disasters suffered by France, which radically affected the future of Europe and the world. Deprived of her most valuable colonies both in the East and in the West, and thoroughly defeated on the continent, her humiliation was the beginning of a new epoch in history. The victorious policy of Pitt destroyed the military prestige which repeated experience had shown to be in France as in no other country the very life of monarchy, and thus was not the least considerable of the many influences that slowly brought about the French Revolution. It effectually deprived her of the lead in the councils of Europe which she had hitherto arrogated to herself, and so affected the whole course of continental politics. It is such far-reaching results as these, and not the mere acquisition of a single colony, however valuable, that constitute Pitt's claim to be considered as on the whole the most powerful minister that ever guided the foreign policy of England.

The first and most important of a series of changes which ultimately led to the dissolution of the ministry was the death of George II. on the 25th of October 1760, and the accession of his grandson, George III. The new king, as was natural, new counsellors of his own, the chief of whom, Lord Bute, was at once admitted to the cabinet as a secretary of state. Between Bute and Pitt there speedily arose an occasion of serious difference.
The existence of the so-called family compact by which the Bourbons of France and Spain bound themselves in an offensive alliance against England having been brought to light, Pitt urged that it should be met by an immediate declaration of war with Spain. To this course Bute would not consent, and as his refusal was endorsed by all his colleagues save Temple, Pitt had no choice but to leave a cabinet in which his advice on a vital question had been rejected. On his resignation, which took place in October 1761, the king urged him to accept some signal mark of royal favour in the form most agreeable to himself. Accordingly he obtained a pension of £3,000 a year for three lives, and his wife, Lady Hester Grenville, whom he had married in 1754, was created Baroness Chatham in her own right. In connexion with the latter gracefully bestowed honour it may be mentioned that Pitt’s domestic life was a singularly happy one.

Pitt’s spirit was too lofty to admit of his entering on any merely factious opposition to the government he had quitted. On the contrary, his conduct after his retirement was distinguished by a moderation and disinterestedness which, as Burke has remarked, “set a seal upon his character.” The war with Spain, in which he had urged the cabinet to take the initiative, proved inevitable; but he scorned to use the occasion for “altercation and recrimination,” and spoke in support of the government measures for carrying on the war. To the preliminaries of the peace concluded in February 1763 he offered an indignant resistance, considering the terms quite inadequate to the successes that had been gained by the country. When the treaty was discussed in parliament in December of the preceding year, though suffering from a severe attack of gout, he was carried down to the House, and in a speech of three hours’ duration, interrupted more than once by paroxysms of pain, he strongly protested against its various conditions. The physical cause which rendered this effort so painful probably accounts for the infrequency of his appearances in parliament, as well as for much that is otherwise inexplicable in his subsequent conduct. In 1763 he spoke against the obnoxious tax on cider, imposed by his brother-in-law, George Grenville, and his opposition, though unsuccessful in the House, helped to keep alive his popularity with the country, which cordially hated the excise and all connected with it. When next year the question of general warrants was raised in connexion with the case of Wilkes, Pitt vigorously maintained their illegality, thus defending at once the privileges of Parliament and the freedom of the press. During 1765 he seems to have been totally incapacitated for public business. In the following year he supported with great power the proposal of the Rockingham administration for the repeal of the American Stamp Act, arguing that it was unconstitutional to impose taxes upon the colonics. He thus endorsed the contention of those who were on the ground of principle, while the majority of those who acted with him contented themselves with resisting the disastrous taxation scheme on the ground of expediency. The Repeal Act, indeed, was only passed pari passu with another censuring the American assemblies, and declaring the authority of the British parliament over the colonies “in all cases whatsoever”; so that the House of Commons repudiated in the most formal manner the principle Pitt laid down. His language in approval of the resistance of the colonics was unusually bold, and perhaps no one but himself could have employed it with impunity at a time when the freedom of debate was only imperfectly conceded.

Pitt had not been long out of office when he was solicited to return to it, and the solicitations were more than once renewed. Unsuccessful overtures were made to him in 1763, and twice in 1765, in May and June—the negotiator in May being the king’s uncle, the duke of Cumberland, who went down in consequence to Hayes, Pitt’s seat in Kent. It is known that he had the opportunity of joining the marquis of Rockingham’s short-lived administration at any time on his own terms, and his conduct in declining an arrangement with that minister has been more generally condemned than any other step in his public life. In July 1766 Rockingham was dismissed, and Pitt was entrusted by the king with the task of forming a government entirely on his own conditions. The result was a cabinet, strong much beyond the average in its individual members, but weak in powerlessness in the diversity of its composition. Burke, in a memorable passage of a memorable speech, has described this “chequered and speckled” administration with great humour, speaking of it as “indeed a very curious show, but utterly unsafe to touch and unsure to stand on.” Pitt chose for himself the office of lord privy seal, which necessitated his removal to the House of Lords; and in August he became earl of Chatham and Viscount Pitt.

By the acceptance of a peerage the great commoner lost at least as much and as suddenly in popularity as he gained in dignity. One significant indication of this may be mentioned. In view of his probable accession to power, preparations were made in the city of London for a banquet and a general illumination to celebrate the event. But the celebration was at once countermanded when it was known that he had become earl of Chatham. The instantaneous revulsion of public feeling was somewhat unreasonable, for Pitt’s health seems now to have been beyond doubt so shattered by his hereditary malady, that he was already in old age though only fifty-eight. It was natural, therefore, that he should choose a sinecure office, and the ease of the Lords. But a popular idol nearly always suffers by removal from immediate contact with the popular sympathy, be the motives for removal what they may.

One of the earliest acts of the new ministry was to lay an embargo upon corn, which was thought necessary in order to prevent a dearth resulting from the unprecedentedly bad harvest of 1766. The measure was strongly opposed, and Lord Chatham delivered his first speech in the House of Lords in support of it. It proved to be almost the only measure introduced by his government in which he personally interested himself. His attention had been directed to the growing importance of the affairs of India, and there is evidence in his correspondence that he was meditating a comprehensive scheme for transferring much of the power of the company to the crown, when he was withdrawn from public business in a manner that has always been regarded as somewhat mysterious. It may be questioned, indeed, whether even had his powers been unimpaired he could have carried out any decided policy on any question with a cabinet representing interests so various and conflicting; but, as it happened, he was incapacitated physically and mentally during nearly the whole period of his tenure of office. He scarcely ever saw any of his colleagues though they repeatedly and urgently pressed for interviews with him, and even an offer from the king to visit him in person was declined, though in the language of profound and almost abject respect which always marked his communications with the court. It has been instigated both by contemporary and by later critics that being disappointed at his loss of popularity, and convinced of the impossibility of co-operating with his colleagues, he exaggerated his malady as a pretence for the inaction that was forced upon him by circumstances. But there is no sufficient reason to doubt that he was really, as his friends represented, in a state that utterly unfitted him for business. He seems to have been freed for a time from the pangs of gout only to be afflicted with a species of mental alienation bordering on insanity. This is the most satisfactory, as it is the most obvious, explanation of his utter indifference in presence of one of the most momentous problems that ever pressed for solution on an English statesman. Those who are able to read the history in the light of what occurred later may perhaps be convinced that no policy whatever initiated after 1766 could have prevented or even materially delayed the declaration of American independence; but to the politicians of that time the coming event had not yet cast so dark a shadow as to paralyse all action, and if they may have had the growing discontent of the colonists and prevented the ultimate dismemberment of the empire, it would have been Lord Chatham. The fact that he not only did nothing to remove existing difficulties, but remained passive while his colleagues took the fatal step which led directly to separation, is in itself clear proof of his entire incapacity. The imposition
of the import duty on tea and other commodities was the project of Charles Townshend, and was carried into effect in 1767 without consultation with Lord Chatham, if not in opposition to his wishes. It is probably the most singular thing in connexion with this singular administration, that its most pregnant measure thus should have been one directly opposed to the well-known principles of its head.

For many months things remained in the curious position that he who was understood to be the head of the cabinet had as little share in the government of the country as an unenfranchised peasant. As the chief could not or would not lead, the subordinates naturally chose their own paths and not his. The lines of Chatham's policy were abandoned in other cases besides the imposition of the import duty; his opponents were taken into confidence; and friends, such as Amherst and Shelburne, were dismissed from their posts. When at length in October 1768 he tendered his resignation on the ground of shattered health, he did not fail to mention the dismissal of Amherst and Shelburne as a personal grievance.

Soon after his resignation a renewed attack of gout freed Chatham from the mental disease under which he had so long suffered. He had been nearly two years and a half in seclusion when, in July 1769, he again appeared in public. He was, however, not long to hold his seat in the House of Lords. He had now almost no personal following, mainly owing to the grave mistake he had made in not forming an alliance with the Rockingham party. But his eloquence was as powerful as ever, and all its power was directed against the government policy in the contest with America, which had become the question of all-absorbing interest. His last appearance in the House of Lords was on the 7th of April 1778, on the occasion of the duke of Richmond's motion for an address praying the king to conclude peace with America on any terms. In view of the hostile demonstrations of France the various parties had come generally to see the necessity of such a measure. But Chatham could not brook the thought of a step which implied submission to the "natural enemy" whom it had been the main object of his life to humble, and he declared for a considerable time, though with sadly diminished vigour, against the motion. After the duke of Richmond had replied, he rose again excitedly as if to speak, pressed his hand upon his breast, and fell down in a fit. He was removed to his seat at Hayes, where he died on the 11th of July 1778. All parties were grieved at his death, and all mourned to show their sense of the national loss. The Commons presented an address to the king praying that the deceased statesman might be buried with the honours of a public funeral, and voted a sum for a public monument which was erected over his grave in Westminster Abbey. Soon after the funeral a bill was passed bestowing a pension of £4,000 a year on his successors in the earldom. He had a family of three sons and two daughters, of whom the second son, William, was destined to add fresh lustre to a name which is one of the greatest in the history of England.

Dr Johnson is reported to have said that "Walpole was a minister given by the king to the people, but Pitt was a minister given by the people to the king," and the remark correctly indicates Chatham's distinctive place among English statesmen. He was the first minister whose main strength lay in the support of the nation at large as distinct from its representatives in the Commons, where his personal following was always small. He was the first to discern that public opinion, though generally slow to form and slow to act, is in the end the paramount power in the state; and he formed in his mind a scheme to rule the country by means of a parliament which would not be a mere instrumentality of the cabinets, but throughout a whole political career. He marks the commencement of that vast change in the movement of English politics by which it has come about that the sentiment of the great mass of the people now tells effectively on the action of the government from day to day,—almost from hour to hour. He was well fitted to secure the sympathy and admiration of his contemporists, for his virtues and his failings were alike English. He was often inconsistent, he was generally intractable and overbearing, and he was always pompous and affected to a degree which, Macaulay has remarked, seems scarcely compatible with true greatness. Of the last quality evidence is furnished in the stilted style of his letters, and in the fact recorded by Seward that he never permitted his under-secretaries to sit in his presence. Burke speaks of "some significant, pompous, creeping, explanatory, ambiguous matter, in the true Chathamic style." But these defects were known only to the inner circle of his associates. To the outside public he was endeared as a statesman who could do or suffer "nothing base," and who had the rare power of transfixing his own indomitable energy and courage into all who served under him. "A spirited foreign policy" has always been popular in England, and Pitt was the most popular of English ministers, because he was the most successful exponent of such a policy. In domestic affairs his influence was small and almost entirely indirect. He himself confessed his unfitness for dealing with questions of finance. The commercial prosperity that was produced by his war policy was in a great part delusive, as prosperity so produced must always be, though it had permanent effects of the highest moment in the rise of such centres of industry as Glasgow. This, however, was a remote result which he could have neither intended nor foreseen.

The correspondence of Lord Chatham, in four volumes, was published in 1818-1821. Sir W. Amherst wrote his Life of Chatham, in 1798. A letter-writer, whose anonymity was afterwards traced to Lord North, published a life of Chatham in 1804. The Rev. Francis Thackeray's History of the Rt. Hon. William Pitt, Earl of Chatham (2 vols., 1827), is a ponderous and shapeless work. Frederic Harrison's Chatham, in the Twelve English Statesmen's series (1885), though skilfully executed, takes a rather academic and somewhat Liberal view. A German work, William Pitt, Graf von Chatham, by Albert von Ruville (3 vols., 1905; English trans., 1907), is the best and most thorough account of Chatham, his period, and his policy, which has appeared. See also the separate article on William Pitt, and the authorities referred to, especially the Rev. William Hunt's appendix i. to his vol. x. of The Political History of England (1905).
CHATHAM ISLANDS

1888, was incorporated with Greenwich Hospital in 1862. In front of the Royal Engineers' Institute is a statue (1890) of General Gordon, and near the railway station another (1888) to Thomas Waghorn, promoter of the overland route to India. In 1905 King Edward VII unveiled a fine memorial arch commemorating Royal Engineers who fell in the South African War. It stands in the parade ground of the Brompton barracks, facing the Crimean Arch. There are numerous brick vaulted, lime-kilns and flour-mills in the district neighbouring to Chatham; and the town carries on a large retail trade, in great measure owing to the presence of the garrison. The fortifications are among the most elaborate in the kingdom. The so-called Chatham Lines enclose New Brompton, a part of the borough of Gillingham. They were begun in 1758 and completed in 1807, but have been completely modernized. They are strengthened by several detached forts and redoubts. Fort Pitt, which rises above the town to the west, was built in 1779, and is used as a general military hospital. It was regarded as the principal establishment of the kind in the country till the foundation of Netley in Hampshire. The lines include the Chatham, the Royal Marine, the Brompton, the Hut, St Mary's and naval barracks; the garrison hospital, Melville hospital for sailors and marines, the arsenal, gymnasium and parade ground for the dress parade prisoners of the extensive dockyard system for which the town is famous. This dockyard covers an area of 516 acres, and has a river frontage of over 3 m. It was brought into its present state by the extensive works begun about 1867. Before that time there was no basin or wet dock, though the river Medway to some extent answered the same purpose, but a portion of the adjoining salt-marshes was then taken in, and three basins have been constructed, communicating with each other by means of large locks, so that ships can pass from the bend of the Medway at Gillingham to that at Upnor. Four graving docks were also formed, opening out of the first (Upnor) basin. Subsequent improvements included dredging operations in the Medway to improve the approach, and the provision of extra dry-dock accommodation under the Naval Works Acts.

The parliamentary borough returns one member. The town was incorporated in 1859, and is governed by a mayor, six aldermen and eighteen councillors. Area, 4335 acres. The borough includes the suburban (an ecclesiastical parish) of Luton, in which are the ancient St John's and St Chathams churches. Chatham (Cetelem, Chatham) belonged at the time of the Domesday Survey to Odo, bishop of Bayeux. During the middle ages it formed a suburb of Rochester, but Henry VIII in founding a regular navy began to establish dockyards, and the harbour formed by the deep channel of the Medway was utilized by Elizabeth, who built a dockyard and established an arsenal here. The dockyard was altered and improved by Charles I. and Charles II., and became the chief naval station of England. In 1708 an act was passed for extending the fortifications of Chatham. During the excavations on Chatham Hill after 1758 a number of tumuli containing human remains, pottery, coins, &c., suggestive of an ancient settlement, were found. Chatham was constituted a parliamentary borough by the Reform Bill of 1832. In the time of Edward III. the lord of the manor had two fairs, one on the 24th of August and the other on the 8th of September. A market to be held on Tuesday, and a fair on the 4th, 5th and 6th of May, were granted by Charles I. in 1679, and another provision market on Saturday by James II. in 1688. In 1738 fairs were held on the 4th of May and the 8th of September, and a market on Tuesday.

CHATHAM ISLANDS, a small group in the Pacific Ocean, forming part of New Zealand, 536 m. due E. of Lyttelton in the South Island, about 44° S., 177° W. It consists of three islands, a large one called Whairikaui, or Chatham Island, a smaller one, Rangihau, or Pitt Island, and a third, Rangitira, or South-east Island. There are also several small rocky islets. Whairikaui, whose highest point reaches about 1000 ft., is remarkable for the number of lakes and tarns it contains, and for the extensive bogs which cover the surface of nearly the whole of the uplands. It is of very irregular form, about 38 m. in length and 25 m. in extreme breadth, with an area of 321 sq. m. — a little larger than Middlesex. The geological formation is principally of volcanic rocks, with schists and tertiary limestone; and an early physical connexion of the islands with New Zealand is indicated by their geology and biology. The climate is colder than that of New Zealand. In the centre of Whairikaui is a large brackish lake called Tewanga, which at the southern end is separated from the sea by a sandbank only 150 yds. wide, which it occasionally bursts through. The southern part of the island has an undulating surface, and is covered either with an open forest or with high ferns. In general the soil is extremely fertile, and where it is naturally drained a rich vegetation of fern and flax occurs. On the north-west are several conical hills of basalt, which are surrounded by oases of fertile soil. On the south-western side is Petre Bay, on which, at the mouth of the river Mantagu, is Waitangi, the principal settlement.

The islands were discovered in 1791 by Lieutenant W. R. Broughton (1762-1821), who gave them the name of Chatham from the brig which he commanded. He described the natives as a bright, pleasure-loving people, dressed in sealskins or mats, and calling themselves Morioris or Maiori. In 1831 they were conquered by 800 Maoris who were landed from a European vessel. They were almost exterminated, and an epidemic of influenza in 1850 killed ten years after they were only 50 survivors out of a total population of 300. They subsequently decreased still further. Their language was allied to that of the Maoris of New Zealand, but they differed somewhat from them in physique, and they were probably a cross between an immigrating Polynesian group and a lower indigenous Melanesian stock. The population of the islands includes about 200 whites of various races and the same number of natives (chiefly Maoris). Cattle and sheep are bred, and a trade is carried on in them with the whalers which visit these seas. The chief export from the group is wool, grown upon runs farmed both by Europeans and Morioris. There is also a small export by the natives of the flesh of young albatrosses and other sea-birds, boiled down and cured, for the Maoris of New Zealand, by whom it is reckoned a delicacy. The imports consist of the usual commodities required by a population where little of the land is actually cultivated.

There are no indigenous mammals; the reptiles belong to New Zealand species. The birds—the largest factor in the fauna have become greatly reduced through the introduction of cats and pigs, as well as by the constant persecution of every sort of animal by the natives. The larger bell-bird (Anthus melanocephala) has become quite scarce; the magnificent fruit-pigeon (Corophaga chathamensis), and the two endemic rails (Neoolumins dieffenbachii and Calabus modestus), the one of which was confined to Whairikaui and the other to Mangare Island, are extinct. Several fossil or subfossil avian forms, very interesting from the point of view of geographical distribution, have been discovered by Dr H. O. Forbes, namely, a true species of raven (Palaeocorax moriorum), a remarkable rail (Diaphorapteryx), closely related to the extinct Aphanapteryx of Mauritius, and a large coot (Palaeolimnas chathamensis). There have also been discovered the remains of a species of swan belonging to the South American genus Chenops, and of the tuatara (Heteria) lizard, the unique species of an ancient family now surviving only in New Zealand. The swan is identical with an extinct species found in caves and kitchen-middens in New Zealand, which was contemporaneous with the prehistoric Maoris and was largely used by them for food. One of the finest of the endemic flowering plants is the group of plants called Chatham Island lilies (Mystipatulum nobile), a gigantic forget-me-not, which grows on the shingly shore in a few places only, and always just on the high-water mark, where it is daily deluged by the waves; while dracophyllums, leuccopogons and arboresecent ragworts are characteristic forms in the vegetation.

CHÂTILLON, the name of a French family whose history has furnished material for a large volume in folio by A. du Chesne, a learned Frenchman, published in 1621. But in spite of its merits this book presents a certain number of inaccurate statements, some of which it is important to notice. If, for instance, it be true that the Châtillons came from Châtillon-sur-Marne (Marne, arrondissement of Reims), the facts are not as they appear to be, for in 1364 this castle belonged to the count of Champagne, and that the head of the house of Châtillon was merely tenant in that place. One of, them, however, Gaucher of Châtillon, lord of Crécy and afterwards constable of France, became in 1390 lord of Châtillon-sur-Marne by exchange, but since 1393 a new agreement allotted to him the countship of Porcien, while Châtillon reverted to the domain of the counts of Champagne. It may be well to mention also that, in consequence of a resemblance of their armorial bearings, du Chesne considered wrongly that the lords of Bazoches and those of Château-Porcien of the 12th and 13th centuries drew their descent from the house of Châtillon.

The most important branches of the house of Châtillon were those of (1) St Pol, beginning with Gaucher III. of Châtillon, who became count of St Pol in right of his wife Isabelle in 1205, the last male of the line being Guy V. (d. 1266); (2) Blois, founded by the marriage of Hugh of Châtillon-St Pol (d. 1248) with Mary, daughter of Margaret of Blois (d. 1250)—this branch became extinct with the death of Guy II. in 1397; (3) Porcien, from 1393 to 1400, when Count John sold the county to Louis, duke of Orleans; (4) Penthivière, by the marriage of Charles of Blois (d. 1364) with Jeanne (d. 1384), heiress of Guy, count of Penthivière (d. 1314), the male line becoming extinct in 1457.

See A. du Chesne, Histoire généalogique de la maison de Châtillon-sur-Marne (1621); Anelme, Histoire généalogique de la maison royale de France, vi. 91-124 (1730).

CHÂTILLON-SUR-SEINE, a town of eastern France, capital of an arrondissement in the department of Côte-d'Or, on the Eastern and Paris-Lyon railways, 67 m. N.N.W. of Dijon, between that city and Troyes. Pop. (1906) 44,350. It is situated on both banks of the upper Seine, which is swollen at its point to the town by the Douix, one of the most abundant springs in France. Châtillon is constructed on ample lines and rendered attractive by beautiful promenades. Some ruins on an eminence above it mark the site of a château of the dukes of Burgundy. Near by stands the church of St Verle of the 10th century, but with many additions of later date; it contains a sculptured Holy Sepulchre of the 16th century and a number of frescoes. In a fine park stands a modern château built by Marshal Marmont, duke of Ragusa, born at Châtillon in 1774. It was burnt in 1871, and subsequently rebuilt. The town preserves several interesting old houses. Châtillon has a subprefecture, tribunals of first instance and of commerce, a school of agriculture and a communal college. Among its industries are brewing, iron-founding and the manufacture of mineral and other blacks. It has trade in wood, charcoal, lithographic and other stone. Châtillon, owned since the 9th century, consists of two parts, parts, belonging to the duchy of Burgundy, and Bourg, ruled by the bishop of Langres; it did not coalesce into one town till the end of the 16th century. It was taken by the English in 1560 and by Louis XI. in 1475, during his struggle with Charles the Bold. Châtillon was one of the first cities to adhere to the League, but suffered severely from the oppression of its garrisons and governors, and in 1555 made voluntary submission to Henry IV. In modern times it is associated with the abortive attempt of 1814 between the representatives of Napoleon and the Allies.

CHATSWORTH, a village of Derbyshire, England, containing a seat belonging to the Duke of Devonshire, one of the most splendid private residences in England. Chatsworth House is situated close to the left bank of the river Derwent, 2½ m. from Bakewell. It is Ionic in style, built foursquare, and enclosing a large open courtyard, with a fountain in the centre. In front, a beautiful stretch of lawn slopes gradually down to the riverside, and a bridge, from which may best be seen the grand façade of the building, as it stands out in relief against the wooded ridge of Banker's Hill. The celebrated gardens are adorned with fountains by Gabriel Cibber; Sir Joseph Paxton designed the great conservatory, unrivalled in Europe, which covers an acre; and the fountains, which include one with a jet 260 ft. high, are said to be surpassed only by those at Versailles. Within the house there is a very fine collection of pictures, including the well-known portraits by Reynolds of Georgiana, Duchess of Devonshire. Other paintings are ascribed to Holbein, Dürrer, Murillo, Jan van Eyck, Dolci, Veronese and Titian. Hung in the gallery of sketches there are some priceless drawings attributed to Michelangelo, Leonardo da Vinci, Raffaello, Correggio, Titian and other masters. Statues by Canova, Thorwaldsen, Chantrey and R. J. Wyatt are included among the sculptures. In the state apartments the walls and window-panes are in some cases inlaid with marble or porphyry; the woodcarving, marvellous for its intricacy, grace and lightness of effect, is largely the work of Samuel Watson of Hanover (d. 1715). Chatsworth Park is upwards of 11 m. in circuit, and contains many noble forest-trees, the whole being watered by the Derwent, and surrounded by high moors and uplands. The state apartments were originally occupied by the Duke of Devonshire, but now it is the model village of Edensor, where most of the cottages were built in villa style, with gardens, by order of the 6th Duke. The parish church, restored by the same benefactor, contains an old brass in memory of John Beaton, confidential servant to Mary, Queen of Scots, who died in 1570; and in the churchyard are the graves of Lord Frederick Cavendish, murdered in 1882 in Phoenix Park, Dublin, and of Sir Joseph Paxton.

Chatsworth (Chatsworde, Chetelsworde, "the court of Chetel") took its name from Chetel, one of its Saxon owners, who held it of Edward the Confessor. It belonged to the crown and was entrusted by the Conqueror to the custody of William Peverell. Chatsworth afterwards belonged for many generations to the family of Leech, and was purchased in the reign of Elizabeth by Sir William Cavendish, husband of the famous Bess of Hardwick. In 1557 he began to build Chatsworth House, and it was completed after his death by his widow, then countess of Shrewsbury. Here Mary, Queen of Scots, spent several years of imprisonment under the care of, and for a time in the same house. During the Civil War Chatsworth was occasionally occupied as a fortress by both parties. It was pulled down, and the present house begun by William, 1st Duke of Devonshire in 1688. The little village consists almost exclusively of families employed upon the estate.

CHATTANOOGA, a city and the county-seat of Hamilton county, Tennessee, U.S.A., in the S.E. part of the state, about 300 m. S. of Cincinnati, Ohio, and 150 m. S.E. of Nashville, Tennessee, on the Tennessee river, and near the boundary line between Tennessee and Georgia. Pop. (1860) 2545; (1870) 6003; (1880) 12,892; (1890) 29,100; (1900) 30,154, of whom 994 were foreign-born and 13,122 were negroes; (U.S. census, 1910) 44,504. The city is served by the Alabama Great Southern (Queen and Crescent), the Cincinnati Southern (leased by the Cincinnati, New Orleans & Texas Pacific railway company), the Nashville, Chattanooga & St Louis (controlled by the Louisville & Nashville), and its leased line, the Western & Atlantic (connecting with Atlanta, Ga.), the Central of Georgia, and the Chattanooga Southern railways; and by freight and passenger steamboat lines on the Tennessee river, which is navigable to and beyond this point during eight months of the year. That branch of the Southern railway extending from Chattanooga to Memphis was formerly the Memphis & Charleston, under which name it became famous in the American Civil War. Chattanooga occupies a picturesque site at a sharp bend of the river. To the south lies Lookout Mountain, whose summit (2126 ft. above the sea; 1495 ft. above the river) commands a magnificent view. To the east rises Missionary Ridge. Fine driveways and electric lines connect with both Lookout Mountain (the summit of which is reached by an inclined plane on which cars are operated by
cable) and Missionary Ridge, where there are Federal reservations, as well as with the National Military Park (15 sq. m.; dedicated 1895) on the battlefield of Chickamauga (q.v.); this park was one of the principal mobilization camps of the United States army during the Spanish-American War of 1898. Among the principal buildings are the city hall, the Federal building, the county court house, the public library, the high school and the St Vincent's and the Baroness Erlanger hospitals. Among Chattanooga's educational institutions are two commercial colleges, the Chattanooga College for Young Ladies (nonsectarian), the Chattanooga Normal University, and the University of Chattanooga, until June 1907, United States Grant University (whose preparatory department, "The Athens School," is at Athens, Tenn.), a co-educational institution under Methodist Episcopal control, established in 1867; it has a school of law (1899), a medical school (1889), and a school of theology (1888). East of the city is a large national cemetery containing more than 13,000 graves of Federal soldiers. Chattanooga is an important producer, lumber, coal and iron market, and is the principal trade and jobbing center for a large district in Eastern Tennessee and Northern Georgia and Alabama. The proximity of coal fields and iron mines has made Chattanooga the principal manufacturing place of importance, its plants including car shops, blast furnaces, foundries, agricultural implements and machinery works, and stove factories; the city has had an important part in the development of the iron and steel industries in this part of the South. There are also flour mills, tanneries (United States Leather Co.), patent medicine, furniture, coffins, woodenware and wagon factories, knitting and spinning mills, planing mills, and sash, door and blind factories—the lumber being obtained from logs floated down the river and by rail. The value of the city's factory products increased from $10,517,886 in 1900 to $15,193,909 in 1905 or 44.5%.

Chattanooga was first settled about 1835, and was long known as Ross's Landing. It was incorporated in 1851 as Chattanooga, and received a city charter in 1866. Its growth for the three decades after the Civil War was very rapid. During the American Civil War it was one of the most important strategic points in the Confederacy, and in its immediate vicinity were fought two great battles. During June 1862 it was threatened by a Federal force under General O. M. Mitchel, but the Confederate army of General Braxton Bragg was transferred thither by rail from Corinth, Miss., before Mitchel was able to advance. In September 1863, however, General W. S. Rosecrans, with the Union Army of the Cumberland out-manoeuvred Bragg, concentrated his numerous columns in the Chickamauga Valley, and occupied the town, to which, after the defeat of Chickamauga (q.v.), he retired.

From the end of September to the 24th of November the Army of the Cumberland was then invested in Chattanooga by the Confederates, whose position lay along Missionary Ridge from its north end near the river towards Rossville, whence their entrenchments extended westwards to Lookout Mountain, which dominates the whole ground, the Tennessee running directly beneath it. Thus Rosecrans was confined to a semicircle of low ground in front of Chattanooga itself, and his supplies had to make a long and difficult détour from Bridgeport, the most direct being under fire from the Confederate position on Lookout and in the Wauhatche valley adjacent. Bragg indeed expected that Rosecrans would be starved into retreat. But the Federals once more, and this time on a far larger scale, concentrated in the face of the enemy. The XI. and XII. corps from Virginia under Hooker were transferred by rail to reinforce Rosecrans; other troops were called up from the Mississippi, and on the 16th of October the Federal government reconstituted the western armies under the supreme command of General Grant. The XV. corps of the Army of the Tennessee, under Sherman, was on the march from the Mississippi. Hooker's troops had already arrived when Grant reached Chattanooga on the 23rd of October. The Army of the Cumberland was now under Thomas, Rosecrans having been recalled. The first action was fought at Brown's Ferry in the Wauhatchee valley, where Hooker executed with complete precision a plan for the revictualling of Chattanooga, established himself near Wauhatchie on the 28th, and repulsed a determined attack on the same night. But Sherman was still far distant, and the Federal forces at Knoxville, against which a large detachment of Bragg's army under Longstreet was now sent, were in grave danger. Grant waited for Sherman's four divisions, but prepared everything for battle in the meantime. His plan was that Thomas in the Chattanooga lines should contain the Confederate centre on Missionary Ridge, while Hooker on the right at Wauhatchie was to attack Lookout Mountain, and Sherman farther up the river was to carry out the decisive attack against Bragg's extreme right wing at the end of Missionary Ridge. The last marches of the XV. corps were delayed by stormy weather, Bragg reinforced Longstreet, and telegraphic communication between Grant and the Federals at Knoxville had already ceased. But Grant would not move forward without Sherman, and the battle of Chattanooga was fought more than two months after Chickamauga. On the 23rd of November a forward move of Thomas's army, intended as a demonstration, developed into a serious and successful action, whereby the first line of the Confederate centre was driven in some distance. Bragg was now much weakened by successive detachments having been sent to Knoxville, and on the 24th the real battle began. Sherman's corps was gradually brought over the river near the mouth of Chickamauga Creek, and formed up on the east side. The attack began at 1 P.M. and was locally a complete success. The heights attacked were in Sherman's hands, and fortified against counter-attack, before nightfall. Hooker in the meanwhile had fought the "Battle above the Clouds" on the steep face of Lookout Mountain, and though opposed by an equal force of Confederates, had completely driven the enemy from the mountain. The 24th then had been a day of success for the Federals, and the decisive attack of the three armies in concert was to take place on the 25th. But the maps deceived Grant and Sherman as they had previously deceived Rosecrans. Sherman had captured, not the north point of Missionary Ridge, but a detached hill, and a new and more serious action had to be fought for the possession of Tunnel Hill, where Bragg's right now lay strongly entrenched. The Confederates used every effort to hold the position and all Sherman's efforts were made in vain. Hooker, who was moving on Rossville, had not progressed far, and Bragg was still free to reinforce his right. Grant therefore directed Thomas to move forward on the centre to relieve the
pressure on Sherman. The Army of the Cumberland was, after all, to strike the decisive blow. About 3.30 p.m. the centre advanced on the Confederate's trenches at the foot of Missionary Ridge. These were carried at the first rush, and the troops were ordered to lie down and await orders. Then occurred one of the most dramatic episodes of the war. Suddenly, and without orders either from Grant or the officers at the front, the whole line of the Army of the Cumberland rose and rushed up the ridge. Two successive lines of entrenchments were carried at once. In a short time the crest was stormed, and after a last attempt at resistance the enemy's centre fled in the wildest confusion. The pursuit was pressed home by the divisional generals, notably by Sheridan. Hooker now advanced in earnest on Rossville, and by nightfall the whole Confederate army, except the troops on Tunnel Hill, was retreating in disorder. These too were withdrawn in the night, and the victory of the Federals was complete. Bragg lost 8684 men killed, wounded and prisoners out of perhaps 34,000 men engaged; Grant, with 60,000 men, lost about 6000.

CHATTLE (for derivation see CATTLE), a term used in English law as equivalent to "personal property," that is, property which, on the death of the owner, devolves on his executor or administrator to be distributed (unless disposed of by will) among the next of kin according to the Statutes of Distributions. Chattles are divided into chattels real and chattels personal. Chattels real are those interests in land for which no "real action" (see Action) lies; estates which are less than freehold (estates for years, at will, or by sufferance) are chattels real. Chattels personal are such things as belong immediately to the person of the owner, and for which, if they are injuriously withheld from him, he has no remedy other than by a personal action. Chattels personal are divided into choses in possession and choses in action (see Chose).

A chattel mortgage, in United States law, is a transfer of personal property, i.e., as security for a debt or obligation in such form that the title to the property will pass to the mortgagee upon the failure of the mortgagor to comply with the terms of the contract. At common law a chattel mortgage might be made without writing, and was valid as between the parties, and even as against third parties if accompanied by possession in the mortgagor, but in most states of the Union legislation now requires a chattel mortgage to be in writing and duly recorded in order to be valid against third parties.

At common law a mortgage may be given only of chattels actually in existence and belonging to the mortgagor, though if he acquired title afterwards the mortgage would be good as between the parties, but not as against subsequent purchasers or creditors. In equity, on the other hand, a chattel mortgage, though not good as a conveyance, is valid as an executory agreement.

Goods and chattels is a phrase which, in its widest signification, includes any property other than freehold. The two words, however, have come to be synonymous, and the expression, now practically confined to wills, means merely things movable in possession.

CHATTERER, a market town in the Wisbech parliamentary division of Cambridgeshire, England, 25½ m. N. by W. of Cambridge by the Great Eastern railway. Pop. of urban district (1901) 4711. It lies in the midst of the flat Fen country. The church of St Peter is principally Decorated; and there are fragments of a Benedictine convent founded in the 10th century and rebuilt after fire in the first half of the 14th. The town has breweries, and engineering and rope-making works. To the north runs the great Forty-foot Drain, also called Vermuyden's, after the Dutch engineer whose name is associated with the fen drainage works of the middle of the 17th century.

CHATTERJI, BANMKIM CHANDRA [BANKIMCHANDRA CHATTERJEE-YAYA] (1838-1894), Indian novelist, was born in the district of the Twenty-four Parganas in Bengal on the 27th of June 1838, and was by caste a Brahman. He was educated at the Hugli College, at the Presidency College in Calcutta, and at Calcutta University, where he was the first to take the degree of B.A. (1858). He entered the Indian civil service, and served as deputy magistrate in various districts of Bengal, his official services being recognized, on his retirement in 1891, by the title of rai bahadur and the C.I.E. He died on the 8th of April 1894.

Bankim Chandra was beyond question the greatest novelist of India during the 19th century, whether judged by the amount and quality of his writings, or by the influence which they have continued to exercise. His education had brought him into touch with the works of the great European romance writers, notably Sir Walter Scott, and he created in India a school of fiction on the European model. His first historical novel, the Durges-Nandini or Chief's Daughter, modelled on Scott, made a great sensation in Bengal; and the Kopala-Kundala and Mrinalini, which followed it, established his fame as a writer whose creative imagination and power of delineation had social been surpassed in India. In 1872 he brought out his first novel, the Bishak-Brikhtka or Poison Tree, which was followed by others in rapid succession. It is impossible to exaggerate the effect they produced; for over twenty years Bankim Chandra's novels were eagerly read by the educated public of Bengal, including the Hindu ladies in the zenanas; and though numerous works of fiction are now produced year by year in every province of India, his influence has increased rather than diminished.

All of his works, however, by far the most important from its astonishing political consequences was the Ananda Math, which was published in 1882, about the time of the agitation arising out of the Ihtib Bill. The story deals with the Sannyasi (i.e. fakir or hermit) rebellion of 1772 near Purnea, Tirhut and Dinapur, and its culminating episode is a crushing victory won by the rebels over the united British and Mussulman forces, a success which was not, however, followed up, owing to the advice of a mysterious "physician" who, speaking as a divinely-inspired prophet, advises Satyananda, the leader of the "children of the Mother," to abandon further resistance since a temporary submission to British rule is a necessity; for Hinduism has become too speculative and unpractical, and the mission of the English in India is to teach Hindus how to reconcile theory and speculation with the facts of science. The general moral of the Ananda Math, then, is that British rule and British education are to be accepted as the only alternative to Mussulman oppression, a moral which Bankim Chandra developed also in his Dharmatattva, an elaborate religious treatise in which he explained his views as to the changes necessary in the moral and religious condition of his fellow-countrymen before they could hope to compete on equal terms with the British and Mahommedans. But though the Ananda Math is in form an apology for the loyal acceptance of British rule, it is none the less inspired by the ideal of the restoration, sooner or later, of a Hindu kingdom in India. This is especially evident in the occasional verses in the book, of which the Bande Mataram is the most famous.

As to the exact significance of this poem a considerable controversy has raged. Bande Mataram is the Sanskrit for "Hail to thee, Mother!" or more literally "I revere thee, Mother!", and according to Dr G. A. Grierson (The Times, Sept. 12, 1906) it can have no other possible meaning than an invocation of one of the "mother" goddesses of Hinduism, in his opinion Kali "the goddess of death and destruction." Sir Henry Cotton, on the other hand (ib. Sept. 13, 1906) sees in it merely an invocation of the "mother-land" Bengal, and quotes in support of this view the free translation of the poem by the late W. H. Lee, a proof which, it may be at once said, is far from convincing. But though, as Dr Grierson points out, the idea of a "mother-land" is wholly alien to Hindu ideas, it is quite possible that Bankim Chandra may have assimilated it with his European culture, and the true explanation is probably that given by Mr. J. D. Anderson in The Times of September 24, 1906. He points out that in the 11th chapter of the 1st book of the Ananda Math the Sannyasi rebels are represented as having erected, in addition to the image of Kali, "the Mother who Has Been," a white marble statue of "the Mother that Shall Be," which is apparently a representation of the mother-land.
The Baner Chatterton

The Bonde Mataram hymn is apparently addressed to both idols.

The poem, then, is the work of a Hindu idealist who personified Bengal under the form of a purified and spiritualized Kali. Of its thirty-six lines, partly written in Sanskrit, partly in Bengali, the greater number are harmless enough. But if the poet sings the praise of the "Mother"

"As Lachmi, bowed in the flower
That in the water grows,"

he also praises her as "Durga, bearing ten weapons," and lines 10, 11 and 12 are capable of very dangerous meanings in the mouths of unscrupulous agitators. Literally translated these run, "She has seventy millions of throats to sing her praise, twice seventy millions of hands to fight for her, how then is Bengal powerless?" As S. M. Mitra points out (Indian Problems, London, 1908), this language is the more significant as the Bonde Mataram in the novel was the hymn by singing which the Sannyasis gained strength when attacking the British forces.

During Bankim Chandra Chatterji's lifetime the Bonde Mataram, though its dangerous tendency was recognized, was not used as a party war-cry; it was not raised, for instance, during the Iltib Bill agitation, or by the students when they marched round the hill during the trial of Surendranath Banerji in 1883. It has, however, obtained an evil notoriety in the agitation that followed the partition of Bengal. That Bankim Chandra himself foresaw or desired any such use of it is impossible to believe. According to S. M. Mitra, he composed it "in a fit of patriotic excitement after a good hearty dinner, which he always enjoyed. It was set to Hindu music, known as the Mollar-Kawali-Tal. The extraordinarily stirring character of the air, and its ingenious assimilation of Bengali passages with Sanskrit, served to make it popular."

Circumstances have made the Bonde Mataram the most famous and the most widespread in its effects of Bankim Chandra's literary works. More permanent, it may be hoped, was the wholesome influence he exercised on the number of literary men he gathered round him, who have left their impress on the literature of Bengal. In his earlier years he served his apprenticeship in literature under Iswar Chandra Vidyasagar, the chief poet and satirist of Bengal during the earlier half of the 19th century. Bankim Chandra's friend and colleague, Dina Bandhu Mitra, was virtually the founder of the modern Bengali drama. Another friend of his, Hem Chandra Banerji, was a poet of recognized merit and talent. And among the younger men who venerated Bankim Chandra, and benefited by his example and advice, may be mentioned two distinguished poets, Nalini Chandra Sen and Rabindra Nath Tagore.

Of Bankim Chandra's novels some have been translated into English by H. A. D. Phillips and by Mrs. M. S. Knight.

CHATTERTON, THOMAS (1752-1770), English poet, was born at Bristol on the 20th of November 1752. His pedigree has a curious significance. The office of sexton of St Mary Redcliffe, at Bristol, one of the most beautiful parish churches in England, had been transmitted for nearly two centuries in the Chatterton family; and throughout the brief life of the poet it was held by his uncle, Richard Phillips. The poet's father, Thomas Chatterton, was a musical genius, somewhat of a poet, a numismatist, and a dabbler in occult arts. He was one of the sub-chanters of Bristol cathedral, and master of the Pyle Street free school, near Redcliffe church. But whatever hereditary tendencies may have been transmitted to him from an early father, the sole drudgery of the boy was repeatedly devolved on his mother, who was in the fourth month of her widowhood at the time of his birth. She established a girls' school, took in sewing and ornamental needlework, and so brought up her two children, a girl and a boy, till the latter attained his eighth year, when he was admitted to Colston's Charity. But the Bristol blue-coat school, in which the curriculum was limited to reading, writing, arithmetic and the Church Catechism, had little share in the education of its marvellous pupil. The hereditary race of sextons had come to regard the church of St Mary Redcliffe as their own peculiar domain; and, under the guidance of his uncle, the child found there his favourite haunt. The knights, ecclesiastics and civic dignitaries, resident on its altar tombs, became his familiar associates; and by and by, when he was able to spell his way through the inscriptions graven on their monuments, he found a fresh interest in certain quaint oaken chests in the muniment room over the porch on the north side of the nave, where parch-ment deeds, old as the Wars of the Roses, long lay unheeded and forgotten. They formed the child's playthings almost from his cradle. He learned his first letters from the illuminated capitals of an old musical folio, and learned to read out of a black-letter Bible. He did not like, his sister said, reading out of small books. Wayward, as it seems, almost from his earliest years, and manifesting no sympathy with the ordinary pastimes of children, he was regarded for a time as deficient in intellect. But he was even then ambitious of distinction. His sister relates that on being asked what device he would like painted on a bowl that was to be his, he replied, "Paint me an angel, with wings, and a trumpet, to trumpet my name over the world."

From his earliest years he was liable to fits of abstraction, sitting for hours in seeming stupor, or yielding after a time to tears, for which he would assign no reason. He had no one near him in sympathy in the strange world of fancy which his imagination had already called into being; and it is easy to see how this helped to foster his natural reserve, and to beget that love of mystery which exercised so great an influence on the development of his genius. When the strange child had attained his sixth year his mother began to recognize his capacity; at eight he was so eager for books that he would read and write all day long if undisturbed; and in his eleventh year he had become a contributor to Felix Farley's Bristol Journal. The occasion of his confirmation inspired some religious poems published in this paper. In 1763 a beautiful cross of curious workmanship, which had adorned the churchyard of St Mary Redcliffe for upwards of three centuries, was destroyed by a churchwarden. The spirit of veneration was strong in the boy, and he sent to the local journal on the 7th of January 1764 a clever satire on the parish Vandal. But his delight was to lock himself in a little attic which he had appropriated as his study; and there, with books, cherished parchments, saved from the loot of the muniment room of St Mary Redcliffe, and drawing materials, the child lived in thought with his 15th-century heroes and heroines. The first of his poems, "The British Hero," was written before he was twelve years old, and he showed his poem to the usher at Colston's hospital, Thomas Phillips, as the work of a 15th-century poet.

Chatterton remained an inmate of Colston's hospital for upwards of six years, and the slight advantages gained from this scanty education are traceable to the friendly sympathy of Phillips, himself a writer of verse, who encouraged his pupils to write. Three of Chatterton's companions are named as youths whom Phillips's taste for poetry stimulated to rivalry; but Chatterton held aloof from these contests, and made at that time no confidant of his own more daring literary adventures. His little pocket-money was spent in borrowing books from a circulating library; and he early ingratiated himself with book collectors, by whose aid he found access to Weever, Dugdale and Collins, as well as to Speght's edition of Chaucer, Spenser and other books.

His "Rowelian" jargon appears to have been chiefly the result of the study of John Kersey's Dictionarium Anglo-Bretonicum, and Prof. W. W. Skeat seems to think his knowledge of even Chaucer was very slight. His holidays were mostly spent at his mother's house; and much of them in the favourite retreat of his attick study there. He had already conceived the romance of Thomas Rowley, an imaginary monk of the 15th century, and lived for the most part in an ideal world of his own, in that elder time when Edward IV. was England's king, and Master William Canyngse—familiar to him among the recumbent effigies in Redcliffe church—still ruled in Bristol's civic chair. Canyngse is represented as an enlightened patron of literature, and Rowley's dramatic interludes were written for
performance at his house. In order to escape a marriage urged by the king, Canyngge retired to the college of Westbury in Gloucestershire, where he enjoyed the society of Rowley, and eventually became dean of the institution. In "The Storie of William Canyngge," one of the shorter pieces of his ingenious romance, his early history is recorded:

"Straight was I carried back to times of yore,
While Canyngge swathed yet in fleshy bed,
And saw all actions which had been before,
And all the scroll of Fate unravelled;
And when the fate-marked babe acomme to sight,
I saw him eager gasping after light.
In all his sheilen gambols and child's play,
In every merrymaking, fair, or wake,
I kena a perplied light of wisdom's ray;
He ate down learning with the wastel-cake;
As wise as any of the aldermen,
He'd wit enow to make a mayor at ten."

This beautiful picture of the childhood of the ideal patron of Rowley is in reality that of the poet himself—"the fate-marked babe," with that wondrous child-genius, and all his romantic dreams realized. The literary masquerade which thus constituted the life-dream of the boy was wrought out by him in fragments of prose and verse into a coherent romance, until the cedulus scholars and antiquaries of his day were persuaded into the belief that there had lain in the parish chest of Redcliffe church for upwards of three centuries, a collection of MSS. of rare merit, the work of Thomas Rowley, an unknown priest of Bristol in the days of Henry VI. and his poet laureate, John Lydgate.

Among the Bristol patrons of Chatterton were two pewterers, George Catcott and his partner Henry Burgum. Catcott was one of the most zealous believers in Rowley, and continued to collect his reputed writings long after the death of his real author. On Burgum, who had risen in life by his own exertions, the blue coat boy paused off the de Bergam pedagogue, and other equally apocryphal evidences of the pewterer's descent from an ancient old as the Norman Conquest. The de Bergam quartering, biazoned on a piece of parchment doubtless recovered from the Redcliffe muniment chest, was itself supposed to have lain for centuries, with that ancient depository. The pedegre was professedly collected by Chatterton from original records, including "The Rowley MSS." The pedegre still exists in Chatterton's own handwriting, copied into a book in which he had previously transcribed portions of antique verse, under the title of "Poems by Thomas Rowley, priest of St. John's, in the city of Bristol;" and in one of these, "The Tournament," Sirr Johan de Berghamme plays a conspicuous part. The ennomed pewterer rewarded Chatterton with five shillings, and was satirized for this valuation of a noble pedegre in some of Chatterton's latest verse.

On the 1st of July 1767, Chatterton was transferred to the office of John Lambert, attorney, to whom he was bound apprentice as a clerk. There he was left much alone; and after fulfilling the routine duties devolving on him, he found leisure for his own favourite pursuits. An ancient stone bridge on the Avon, built in the reign of Henry II., and altered by many later additions into a singularly picturesque but inconvenient thoroughfare, had been displaced by a structure better adapted to modern requirements. In September 1768, when Chatterton was in the second year of his apprenticeship, the new bridge was partially opened for traffic. Shortly afterwards the editor of Felix Farley's Journal received from a correspondent, signing himself Dunelmus Bristoliensis, a "description of the mayor's first passing over the old bridge," professedly derived from an ancient MS. William Barrett, F.S.A., surgeon and antiquary, who was then accumulating materials for a history of Bristol, secured the original manuscript, which is now preserved in the British Museum, along with other Chatterton MSS., most of which were ultimately incorporated by the cedulus antiquary into a learned quarto volume, entitled the History and Antiquities of the City of Bristol, published nearly twenty years after the poet's death. It was at this time that the definite story made its appearance—over which critics and antiquaries wrangled for nearly a century—his numerous ancient poems and other MSS. taken by the elder Chatterton from a cofin in the muniment room of Redcliffe church, and transcribed, and so rescued from oblivion, by his son. The pieces include the "Bristowe Tragedie, or the Dethe of Sry Charles Bawdin," a ballad celebrating the death of the Lancastrian knight, Charles Baldwin; "Ellia," a "Tragical Enterlude," as Chatterton styles it, but in reality a dramatic poem of sustained power and curious originality of structure; "Goddwyn," a dramatic fragment; "Tournameent," "Battle of Hastings," "The Parliament of Sprites," "Balade of Charitie," with numerous shorter pieces, forming altogether a volume of poetry, the rare merit of which is indisputable, wholly apart from the fact that it was the production of a mere boy. Unfortunately for him, his ingenious romance had either to be acknowledged as his own creation, and so in all probability be treated with contempt, or it had to be sustained by the manufacture of spurious antiques. To this accordingly Chatterton resorted, and found no difficulty in gulling the most learned of his cedulus dupes with his parchments.

The literary labours of the boy, though diligently pursued at his master, were not allowed to interfere with the duties of Mr Lambert's office. Nevertheless the Bristol attorney used to search his apprentice's drawer, and tear up any poems or other manuscripts that he could lay his hands upon; so that it was only during the absences of Mr Lambert from Bristol that he was able to expend his unemployed time in his favourite pursuits. But repeated allusions, both by Chatterton and others, seem to indicate that such intervals of freedom were of frequent occurrence. Some of his modern poems, such as the piece entitled "Resignation," are of great beauty; and these, with the satires, in which he took his revenge on all the local celebrities whose vanity or meanness had excited his ire, are alone sufficient to fill a volume. The Catcotts, Burgum, Barrett and others of his patrons, figure in these satires, in impudent yet discriminating caricature, along with mayor, aldermen, bishop, dean and other notabilities of Bristol. Towards Lambert his feelings were of too keen a nature to find relief in such sarcasm.

In December 1768, in his seventeenth year, he wrote to Dodson, the London publisher, offering to procure for him "copies of several ancient poems, and an interlude, perhaps, of a poetic dramatic piece extant," and wrote to the Rowleys, a priest in Bristol, who lived in the reigns of Henry VI. and Edward IV. To this letter he appended the initials of his favourite pseudonym, Dunselmus Bristoliensis, but directed the answer to be sent to the care of Thomas Chatterton, Redcliffe Hill, Bristol. To this, as well as to another letter enclosing an extract from the tragedy of "Ellia," no answer appears to have been returned. Chatterton, conceiving the idea of finding sympathy and aid at the hand of some modern Canyngge, betook himself to Horace Walpole, who not only indulged in a medieval renaisance of his own, but was the reputed author of a spurious antique in the Castle of Otranto. He wrote to him offering him a document entitled "The Ruse of Pewtynceye yn Engleonde, written by T. Rowleie, 1469, for Mastre Canyngye," accompanied by notes which included specimens of Rowley's poetry. To this Walpole replied with courteous acknowledgments. He characterized the verses as "wonderful for their harmony and spirit," and added, "Give me leave to ask you where Rowley's poems are to be had? I should not be sorry to print them; or at least a specimen of them, if they have never been printed." Chatterton replied, enclosing additional specimens, and sending a verse or two, and said that he was the son of a poor widow, and clerk to an attorney, but had a taste for more refined studies; and he hinted a wish that he might help him to some more congenial occupation. Walpole's manner underwent an abrupt change. The specimens of verse had been submitted to his friends Gray and Mason, the poets, and pronounced modern. They did not thereby forfeit the wonderful harmony and spirit which Walpole had already professed to recognize in them. But he now coldly advised the boy to stick to the attorney's office; and "when he should have made a fortune," he might betake himself to more favourite
studies. Chatterton had to write three times before he recovered his MSS. Walpole has been loaded with more than his just share of responsibility for the fate of the unhappy poet, of whom he admitted when too late, “I do not believe there ever existed so masterly a genius.”

Chatterton now turned his attention to periodical literature and politics, and exchanged Felix Paley's Bristol Journal for the Town and County Magazine and other London periodicals. Assuming the vein of Junius—then in the full blaze of his triumph—he turned his pen against the duke of Grafton, the earl of Bute, and the princess of Wales. He had just despatched one of his political diatribes to the Middlesex Journal, when he sat down on Easter Eve, 17th April 1770, and penned his “Last Will and Testament,” a strange satirical compound of jest and earnest, in which he intimated his intention of putting an end to his life the following evening. Among his satirical bequests, such as his “humility” to the Rev. Mr Camplin, his “religion to Dean Barton, and his ‘modesty’ along with his “prosody and grammar” to Mr Burgum, he leaves “to Bristol all his spirit and disinterestedness, parcels of goods unknown on its quay since the days of Canyng and Rowley.” In more genuine earnestness he recalls the name of Michael Clayfield, a friend to whom he owed intelligent sympathy. The will was probably purposely prepared in order to frighten his master into letting him go. If so, it had the desired effect. Lambert cancelled his indentures; his friends and acquaintance made him up a purse; and on the 25th or 26th of the month he arrived in London.

Chatterton was already known to the readers of the Middlesex Journal as a rival of Junius, under the nom de plume of Decimus. He had also been a contributor to Hamilton's Town and Country Magazine, and speedily found access to the Freetholder's Magazine, another political miscellany strange to Wilkes and liberty. His contributions were freely accepted; but the editors paid little or nothing for them. He wrote in the most hopeful terms to his mother and sister, and spent his first earnings in buying gifts for them. Art, pride and ambition were amply gratified by the promises and interested flattery of editors and political adventurers; Wilkes himself had noted his trenchant style, “and expressed a desire to know the author”; and Lord Mayor Beckford graciously acknowledged a political address of his, and greeted him “as politely as a citizen could.” But of actual money he received but little. He was extremely abstemious, his diligence was great, and his versatility wonderful. He could assume the style of Junius or Smollett, reproduce the satric bitterness of Churchill, parody Macpherson's Ossian, or write in the manner of Pope, or with the polished grace of Gray and Collins. He wrote political letters, eclogues, lyrics, operas and satires, both in prose and verse. In June 1770—after Chatterton had been some nine weeks in London—he removed from Shoreditch, where he had hitherto lodged with a relative, to an attic in Brook Street, Holborn. But for most of his productions the payment was delayed; and now state prosecutions of the press rendered him more and more apprehensive of his own safety, and threw him back on the lighter resources of his pen. In Shoreditch, as in his lodgings at the Bristol attorney's, he had only shared a room; but now, for the first time, he enjoyed uninterrupted solitude. His bed-fellow at Mr Walmsley's, Shoreditch, noted that much of the night was spent by him in writing; and now he could write all night. The romance of his earlier years revived, and he transcribed from an imaginary parchment of the old priest Rowley his “Excellente Balade of Charity.” This fine poem, perversely disguised in archaic language, he sent to the editor of the Town and County Magazine, and had it rejected.

The high hopes of the sanguine boy had begun to fade. He had not yet completed his second month in London, and already failure and starvation stared him in the face. Mr Cross, a neighbouring apothecary, repeatedly invited him to join him at dinner or supper; but he refused. His landlady also, suspecting his necessity, pressed him to share her dinner, but in vain. “She knew” as she afterwards said, “that he had not eaten anything for two or three days.” But he was offended at her urgency, and assured her that he was not hungry. The note of his actual receipts, found in his pocket-book after his death, shows that Hamilton, Fell and other editors who had been so liberal in flattery, had paid him a total of eightpence each for his songs; and somewhat less than eightpence for each of his poems; while much which had been accepted was held in reserve, and still unpaid for. The beginning of a new month revealed to him the indefinite postponement of the publication and payment of his work.

He had wished, according to his foster-mother, to study medicine with Barrett; in his desperation he now reverted to this, and wrote to Barrett for a letter to help him to an opening as a surgeon's assistant on board an African trader. He appealed also to Mr Catcott to forward his plan, but in vain. On the 24th of August 1770, he retired for the last time to his attic in Brook Street, carrying with him the arsenic which he there drank, after tearing into fragments whatever literary remains were at hand.

He was only seventeen years and nine months old; but the best of his numerous productions, both in prose and verse, require no allowance to be made for the immature years of their author, when comparing him with the ablest of his contemporaries. He pictures Lydgate, the monk of Bury St Edmunds, challenging Rowley to a trial at versemaking, and under cover of this fiction, produces his “Song of Æilla,” a piece of rare lyrical beauty, worthy of comparison with any antique or modern production of its class. Again, in his “Tragedy of Godwyn,” of which only a fragment has been preserved, the “Ode to Liberty,” with which it abruptly closes, may claim a place among the finest martial lyrics in the language. The collection of poems in which such specimens occur furnishes by far the most remarkable example of intellectual precocity in the whole history of letters. Collins, Burns, Keats, Shelley and Byron all awaken sorrow over the premature arrestment of their genius; but the youngest of them survived to his twenty-fifth year, while Chatterton was not eighteen when he perished in his miserable garret. The death of Chatterton attracted little notice at the time; for the few who then entertained any appreciative estimate of the Rowley poems are discussed in A. Kippis, Biographia Britannica (vol. iv., 1789), where there is a detailed account by G. Gregory of Chatterton's life (pp. 573-619). This was reprinted in the edition (1803) of Chatterton's Works by F. and J. C. Taylor, who had been his foster brother's sister. The neglected condition of the study of earlier English in the 19th century alone accounts for the temporary success of Chatterton's mystification. It has long been agreed that Chatterton was responsible for the fashionable use of the archaic and the imitation of archaic style are analysed in confirmation of this view by Prof. W. W. Skeat in an introductory essay prefixed to vol. ii. of The Poetical Works of Thomas Chatterton (1871) in the “Aldine Edition of the Poets.” This volume is the last to be issued by Edward B. Thomas. Of the Rowley poems there is modernized, and many of the archaic words are replaced by modern equivalents provided in many cases from Chatterton's own notes, the theory being that Chatterton usually composed in modern English, and inserted his peculiar words and his complicated orthography afterwards. For some criticism of Prof. Skeat's success in the very difficult task of reconstituting the text, see H. B. Forman, Thomas Chatterton and his latest Editor (1874).
CHATTI—CHAUCER

The Chatterton MSS., originally in the possession of William Barrett of Bristol, were left by his heir to the British Museum in 1800. Others are preserved in the Bristol library.

Chatterton's genius and his tragic death are commemorated by S. T. Coleridge in "The Monody on the Death of Chatterton," by D. G. Rossetti in "Five English Poets," and John Keats inscribed Anthemion to the memory of Thomas Chatterton. Alfred de Vigny's biography of the poet was the first attempt at an accurate account of the poet. Herbert Croft (q.v.), in his Love and Madness, interpolated a long and valuable account of Chatterton, giving many of the poet's letters, and much information obtained from his family and friends (pp. 125-244, letter II.). There is a valuable collection of "Chattertoniana" in the British Museum, consisting of separate works by Chatterton, newspaper cuttings, articles, dealing with the Rowley controversy and other subjects, with MS. notes by Joseph Haslewood, Wiener (1900).

Among biographies of Chatterton may be mentioned Chatterton: A Biographical Study (1869), by Daniel Wilson; Chatterton: A Biography (1820; first printed 1856 in a volume of essays), by D. Mason; Thos. Chatterton (1900), by J. H. Hesse-Cassel; and Wiener Beiträge zur engl. Philologie; Chatterton, by C. E. Russell (1909).

CHATTI, an ancient Germanic tribe inhabiting the upper reaches of the rivers Weser, Eder, Fulda and Werra, a district approximately corresponding to Hesse-Cassel, though probably somewhat more extensive. They frequently came into conflict with the Romans during the early years of the 1st century. Eventually they formed a portion of the Franks and were incorporated in the kingdom of Clovis probably with the Ripuarii, at the beginning of the 6th century.

CHAUCER, GEOFFREY (? 1340-1400), English poet. The name Chaucer, a French form of the Latin caelebratus, a shoemaker, is found in London and the eastern counties as early as the second half of the 13th century. Some of the London Chaucers lived in Cordwainers Street. In the household accounts of several of them, however, were vintners, and among others the poet's father John, and probably also his grandfather Robert. Legal legacies inform us that in December 1324 John Chaucer was not much over twelve years old, and that he was still unmarried in 1328, the year which used to be considered that of Geoffrey's birth. The poet was probably born from eight to twelve years later, since in 1336, when giving evidence in Sir Richard le Scrope's suit against Sir Robert Grosvenor as to the right to bear certain arms, he was set down as "del age de xl ans et plus, armez par xxvij ans." At a later date, and probably at the time of the poet's birth, his father lived in Thames Street, and had to wife a certain Agnes, niece of Hamo de Compton, whom we may regard as Geoffrey Chaucer's mother. In 1357 Geoffrey is found, apparently as a lad, in the service of Elizabeth, countess of Ulster, wife of Lionel, duke of Clarence, and of his three sisters, the two leaves of her household accounts, accidentally preserved, showing that she paid in April, May, and December various small sums for his clothing and expenses. In 1359, as we learn from his deposition in the Scrope suit, Chaucer went to the war in France. At some period of the campaign he was at "Retters," i.e., Rethel, near Reims, and subsequently had the ill luck to be taken prisoner. On the 1st of March 1360 the king contributed £16 to his ransom, and by a year or two later Chaucer must have entered the royal service, since on the 20th of June 1367 Edward granted him a pension of twenty marks for his past and future services. A pension of ten marks had been granted by the king the previous September to a Philippa Chaucer for services to the queen as one of her "dominicias" or "damoselles," and it seems probable that at this date Chaucer was already married and this Philippa his wife, a conclusion which used to be resisted on the ground of allusions in his early poems to a hopeless love-affair, now reckoned part of his poetical outfit. Philippa is usually said to have been one of two daughters of a Sir Payne Roet, the other being Katherine, who after the death of her first husband, Sir Hugh de Swynford, in 1372, became governess to John of Gaunt's children, and subsequently his mistress and (in 1396) his wife. It is possible that Philippa was sister to Sir Hugh and sister-in-law to Katherine. In either case the marriage helps to account for the favour subsequently shown to Chaucer by John of Gaunt.

In the grant of his pension Chaucer is called "dilectus valletus noster," our beloved yeoman; before the end of 1368 he had risen to be one of the king's esquires. In September of the following year John of Gaunt's wife, the duchess Blanche, died at the age of twenty-nine, and Chaucer wrote in her honour The Book of the Duchesse, a poem of 1334 lines in octosyllabic couplets, the first of his undoubtedly genuine works which can be connected with a definite date. In June 1370 he went abroad on the king's service, though on what errand, or whether it took him, is not known. He was back probably some time before Michaelmas, and seems to have remained in England till the 1st of December 1372, when he started, with an advance of 100 marks in his pocket, for Italy, as one of the three commissioners to treat with the Genoese as to an English port where they might have special facilities for trade. The accounts which he delivered on his return on the 23rd of May 1373 show that he had also visited Florence on the king's business, and he probably went also to Padua and there made the acquaintance of Petrarch.

In the second quarter of 1374 Chaucer lived in a whirl of prosperity. On the 23rd of April the king granted him a pitcher of wine daily, subsequently commuted for an annuity of 20 marks. From John of Gaunt, who in August 1372 had granted Philippa Chaucer £10 a year, he himself now received (June 13) a like annuity in reward for his own and his wife's services. On the 8th of June he was appointed Comptroller of the Custom and Subsidy of Wools, Hides and Woodrells and also of the Petty Customs of Wine in the Port of London. A month before this appointment, and probably in anticipation of it, he took (May 10, 1374) a lease for life from the city of London of the dwelling-house above the gate of Aldgate, and here he lived for the next twelve years. His own and his wife's income now amounted to over £60, the equivalent of upwards of £1000 in modern money. In 1376 he obtained from the king in the form of two wards of Kentish heirs, one of whom paid him £104, and a grant of £11: 4: 6; the value of some confiscated wool. In December 1376 he was sent abroad on the king's service in the retinue of Sir John Burley; in February 1377 he was sent to Paris and Montreuil in connexion probably with the peace negotiations between England and France, and at the end of April (after a reward of £20 for his good services) he was again despatched to France.

On the accession of Richard II. Chaucer was confirmed in his offices and pensions. In January 1378 he seems to have been in France in connexion with a proposed marriage between Richard and the daughter of the French king; and on the 28th of May of the same year he was sent with Sir Edward de Berkeley to the lord of Milan and Sir John Hawkwood to treat for help in future wars, returning on the 9th of September. This was his last diplomatic journey, and the course of a period of his life generally considered to have been so unprofitable to poetry that little beyond the Clerk's "Tale of Grisilde," one or two other of the stories afterwards included in the Canterbury Tales, and a few short poems, are attributed to it, though the poet's actual absences from England during the eight years amount to little more than eighteen months. During the next twelve or fifteen years there is no question that Chaucer was constantly engaged in literary work, though for the first half of them he had no lack of official employment. Abundant favour was shown him by the new king. He was paid £32 as a reward for his later missions in Edward III.'s reign, and was allowed an annual gratuity of 10 marks in addition to his pay of £10 as comptroller of the customs of wool. In April 1382 a new comptrollership, that of the petty customs in the Port of London, was given him, and shortly after he was allowed to exercise it by deputy, a similar licence being given him in February 1385, at the instance of the earl of Oxford, as regards the comptrollership of wool. In October 1385 Chaucer was made a justice of the peace for Kent. In February 1386 we catch a glimpse of his wife Philippa being admitted to the fraternity of Lincoln cathedral in the company of Henry, earl of
CHAUCER

Derby (afterwards Henry IV.), Sir Thomas de Swynford and other distinguished persons. In August 1386 he was elected one of the two knights of the shire of Kent, and with this dignity, though it was one not much appreciated in those days, his good fortune reached its climax. In December of the same year he was superseded in both his comptrollerships, almost certainly as a result of the absence of his patron, John of Gaunt, in Spain, and the supremacy of the duke of Gloucester. In the following year the cessation of Philippa's pension suggests that she died between Midsummer and Michaelmas. In May 1388 Chaucer surrendered to the king his two pensions of 20 marks each, and they were re-granted at his request to one John Scally. The transaction was unusual and probably points to a pressing need for ready money, nor for the next fourteen months do we know of any source of income possessed by Chaucer beyond his annuity of £10 from John of Gaunt.

In July 1389, after John of Gaunt had returned to England, and the king had taken the government into his own hands, Chaucer was appointed clerk of the works at various royal palaces at a salary of two shillings a day, or over £31 a year, worth upwards of ££200 in 1389. This was probably to give him charge of some repairs at St George's Chapel, Windsor. He was also made a commissioner to maintain the banks of the Thames between Woolwich and Greenwich, and was given by the earl of March (grandson of Lionel, duke of Clarence, his old patron) a sub-forestery at North Petherton, Devon, obviously a sinecure. While on the king's business, in September 1390, Chaucer was twice robbed by highwaymen, losing £20 of the king's money. In June 1391 he was superseded in his office of clerk of the works, and seems to have suffered another spell of misfortune, of which the first alleviation came in January 1393 when the king made him a present of £10. In February 1394 he was granted a new pension of £20. It is possible, also, that about this time, or a little later, he was in the service of the earl of Derby. In 1397 he received from King Richard a grant of a butt of wine yearly. For this he appears to have asked in terms that suggest poverty, and in May 1398 he obtained letters of protection against his creditors, a step perhaps rendered necessary by an action for debt taken against him earlier in the year. On the accession of Henry IV. a new pension of 40 marks was conferred on Chaucer (13th of October 1399) and Richard IL's grants were formally confirmed. Henry himself, however, was probably straitened for ready money, and no instalment of the new pension was paid during the few months of his reign that the poet lived. Nevertheless, on the strength of his expectations, on the 24th of December 1399 he leased a tenement in the garden of St Mary's Chapel, Westminster, and it was probably here that he died, on the 25th of the following October. He was buried in Westminster Abbey, and his tomb became the nucleus of what is now known as Poets' Corner.

The portrait of Chaucer, which the affection of his disciple, Thomas Hoccleve, caused to be painted in a copy of the latter's Regiment of Princes (now Harlcan MS. 4866 in the British Museum), shows him an old man with white hair; he has a fresh complexion, grey eyes, a straight nose, a grey moustache and a small double-pointed beard. His dress and attire are black, and he carries in his hands a string of beads. We may imagine that this was thus that during the last months of his life he used to walk about the precincts of the Abbey.

Henry IV.'s promise of an additional pension was doubtless elicited by the Compendy to His Pius, in the envoy to which works Chaucer addresses himself as the "conqueror of Brutes Albion." Thus within the last year of his life the poet was still writing. Nevertheless, as early as 1393-1394, in lines to his friend Scogan, he had written as if his day for poetry was past, and it seems probable that his longer poems were all composed before this date. In the preceding fifteen—or, if another view be taken, twenty—years, his literary activity was very great, and with the aid of the lists of his works which he gives in the Legende of Good Women (lines 414-431), and the talk on the road which precedes the "Man of Law's Tale" (Canterbury Tales, B. 46-70), the order in which his main works were written can be traced with approximate certainty, a work of both of the and of the minor poems can be connected with definite dates.

The development of his genius has been attractively summed up as comprised in three stages, French, Italian and English, and there is a rough approximation to the truth in this formula, since his earliest poems are translated from the French or based on French models, and the two great works of his middle period are borrowed from the Italian, while his latest stories have no such obvious and direct originals and in their humour and freedom anticipate the typically English temper of Henry Fielding. But Chaucer's indebtedness to French poetry was no passing phase. For various reasons—a not very remote French origin of his own family may be one of them—he was in no way interested in older English literature or in the work of his English contemporaries, save possibly that of "the moral Gower." On the other hand he knew the Roman de la rose as modern English poets know Shakespeare, and the full extent of his debt to his French contemporaries, not merely in 1360, but in 1385 and in 1393 (the dates are approximate), is only gradually being discovered. To be in touch throughout his life with the best French poets of the day was much for Chaucer. Even with this stimulus alone he might have developed no small part of his genius. But it was his great good fortune to add to this continuing French influence, lessons in plot and construction derived from Boccaccio's Filostrato and Teseide, as well as some glimpses of the higher art of the Divina Commedia. He shows acquaintance also with one of Petrarch's sonnets, and though, when all is said, the Italian books with which he can be proved to have been intimate are but few, they sufficed. His study of them was but an episode in his literary life, but it was an episode of unique importance. Before it began he had already been making his own artistic experiments, and it is noteworthy that while he learnt so much from Boccaccio he improved on his originals as he translated them. Doubtless his busy life in the service of the crown had taught him self-confidence, and he uses his Italian models in his own way and with the most triumphant and assured success. When he had no more Italian poems to adapt he had his own lesson. The art of weaving a plot out of his own imagination was never his, but he could take what might be little more than an anecdote and lend it body and life and colour with a skill which has never been surpassed.

The most direct example of Chaucer's French studies is his translation of Le Roman de la rose, a poem written in some 400 lines by Guillaume Lorris about 1257 and extended to over 22,000 by Jean Cipinel, better known as Jean de Meun, forty years later. We know from Chaucer himself that he translated this poem, and the extant English fragment of 7608 lines was generally assigned to him from 1532, when it was first printed, till its authorship was challenged in the early years of the Chaucer Society. The ground of this challenge was its wide divergence from Chaucer's practice in his undoubtedly genuine works as to certain niceties of rhyme, notable as to not rhyming words ending in -y with others ending -ye. It was subsequently discovered, however, that the whole fragment was divisible linguistically into three portions, of which the first and second end respectively at lines 1705 and 3810, and that in the first of these three sections the variations from Chaucer's accepted practice are insignificant. Lines 1-1705 have therefore been provisionally accepted as Chaucer's, and the other two fragments as the work of unknown translators (James I. of Scotland has been suggested as one of them), which somehow came to be pieced together. If, however, the difficulties in the way of this theory are less than those which confront any other, they are still considerable, and the question can hardly be treated as closed.

While our knowledge of Chaucer's Roman of the Rose is in this unsatisfactory state, another translation of his from the French, the Book of the Lyon (alluded to in the "Retraction" found, in some manuscripts, at the end of the Canterbury Tales), which must certainly have been taken from Guillaume

1 The positions of the House of Fame and Palamon and Arcyde are still matters of controversy.

1
Machaut’s *Le Dit du Lion* has perished altogether. The strength of French influence on Chaucer’s early work may, however, be amplified from the first of his poems with which we are on sure ground, the *Book of the Duchess*, or, as it is alternatively called, the *Deth of Blaunce*. Here not only are individual passages closely imitated from Machaut and Froissart, but the dream, the May morning, and the whole machinery of the poem are taken over from contemporary French conventions. But even at this stage Chaucer could prove his right to borrow by the skill with which he makes his materials serve his own purpose, and some of the lines in the *Deth of Blaunce* are among the most tender and charming he ever wrote.

Chaucer’s *A.B.C.*, a poem in honour of the Blessed Virgin, of which the stanzas begin with the successive letters of the alphabet, is another early example of French influence. It is taken from the *Pelerinage de la vie humaine*, written by Guillaume de Deguilville about 1330. The occurrence of some magnificent lines in Chaucer’s version, combined with evidence that he did not yet possess the skill to translate at all literally as soon as rhymes had to be considered, accounts for this poem having been dated sometimes earlier than the *Book of the Duchess*, and sometimes several years later. With it is usually moved up and down, though it should surely be placed in the ‘seventies, the *Compleynt to Pity*, a fine poem which yet, from its slight obscurity and absence of Chaucer’s usual ease, may very well some day prove to be a translation from the French.

While Chaucer thus sought to reproduce both the matter and the style of French poetry in England, he found other materials in popular Latin books. Among his lost works are renderings of “Origenes upon the Maudeleyn,” and of Pope Innocent III. on “The Wreced Engendring of Mankind” (*De miseriae condicionis humanae*). He must have begun his attempts at straightforward narrative with the *Lyf of Seynt Cecyle* (the weakest of all his works, the second Nun’s Tale in the *Canterbury* series) from the *Legenda Aurea* of Jacobus de Voragine, and the story of the patience of Grisilde, taken from Petrarch’s Latin version of a tale by Boccaccio. In both of these he condenses a little, but ventures on very few changes, though he lets his readers see his impatience with his originals. In his story of Constance (afterwards ascribed to the Man of Law), taken from the Anglo-Norman chronicle of Nicholas Trivet, written about 1334, we find him struggling to put some substance into another weak tale, but still without the courage to remedy its radical faults, though here, as with Grisilde, he does as much for his heroine as the conventional exaltation of one virtue at a time permitted. It is possible that other tales which now stand in the *Canterbury* series were written originally at this period. What is certain is that at some time in the ‘seventies three or four Italian poems passed into Chaucer’s possession, and that he set to work busily to make use of them. One of the most interesting of the poems so claimed for him by Professor Skeat is a fragmentary “Compleynt,” part of which is written in *terza rima*. While he thus experimented with the metre of the *Divina Commedia*, he made his first attempt to use the material provided by Boccaccio’s *Teseide* in another fragment of great interest, that of *Quene Anelida and Fal Arcyte*. More than a third of this is taken up with another, and quite successful, metrical experiment in Anelida’s “compleynt,” but in the introduction of Anelida herself Chaucer made the first of his three unsuccessful efforts to construct a plot for an important poem out of his own head, and the fragment which begins so well breaks off abruptly at line 357.

For a time the *Teseide* seems to have been laid aside, and it was perhaps at this moment, in despondency at his failure, that Chaucer wrote his most important prose work, the translation of the *De Consolatione Philosophiae* of Boethius. Reminiscences of this helped to enrich many of his subsequent poems, and inspired five of his shorter pieces (*The Former Age*, *Fortune*, *Truth*, *Gentilesse* and *Lah of Siedfastnesse*), but the translation itself was only a partial success. To borrow his own phrase, his “Englysh was insufficient” to reproduce such difficult Latin. The translation is often barely intelligible without the original, and it is only here and there that it flows with any ease or rhythm.

If Chaucer felt this himself he must have speedily con- sold by achieving in *Troilus and Criseyde* his greatest artistic triumph. Warned by his failure in *Anelida* and *ArCYte*, he was content this time to take his plot unaltered from the *Filastro*, and to follow Boccaccio step by step through the poem. But he did not follow him as a mere translator. He had done his duty manfully for the saints “of other holiness” in *Cyece*, Grisilde and Constance, whom he was forbidden by the rules of the game to clothe with complete flesh and blood. In this great love-story there were no such restrictions, and the characters which Boccaccio’s treatment left thin and conventional became in Chaucer’s hands convincingly human. No other English poem is so instinct with the glory and tragedy of youth, and in the details of the story Chaucer’s gifts of vivid colouring, of humour and pity, are all at their highest.

An unfortunate theory that the reference in the *Legende of Good Women* to “at the love of Palamond and Arcyte” is to a hypothetical poem in seven-line stanzas on this theme, which Chaucer is imagined, when he came to plan the *Canterbury Tales*, to have suppressed in favour of a new version in heroic couplets, has obscured the close connexion in temper and power between what we know as the “Knight’s Tale” and the *Troilus*. The poem may have been more or less extensively revised before, with admirable fitness, it was assigned to the Knight, but that its main composition can be separated by several years from that of *Troilus* is aesthetically incredible. Chaucer’s art here again is at its highest. He takes the plot of Boccaccio’s *Teseide*, but only as much of it as he wants, and what he takes he heightens and humanizes with the same skill which he had shown in transforming the *Filastro*. Of the individual characters Theseus himself, the arbiter of the plot, is most notably developed; Emilie and her two lovers receive just as much individuality as they will bear without disturbing the atmosphere of romance. The whole story is pulled together and made more rapid and effective. A comparison of almost any scene as told by the two poets suffices to show Chaucer’s immense superiority. At some subsequent period the “Squire’s Tale” of Cambuscan, the fair Canacee and the Horse of Brass, was gallantly begun in something of the same key, but Chaucer took for it more materials than he could use, and for lack of the help of a leader like Boccaccio he was obliged to leave the story, in Milton’s phrase, “half-told,” though the fragment written certainly takes us very much less than half-way.

Meanwhile, in connexion (as is reasonably believed) with the betrothal or marriage of Anne of Bohemia to Richard II. (*i.e.* about 1381–1382), Chaucer had brought to a successful completion the *Parlement of Fonkes*, a charming sketch of 699 lines, in which the other birds, on Saint Valentine’s day, counsel the “Forrmel Egle” on her choice of a mate. His success here, as in the case of the *Deth of Blaunce the Duchess*, was due to the absence of any need for a climax; and though the materials which he borrowed were mainly Latin (*with his help from passages of the Teseide not fully needed for Palamond and Arcyte*) his method of handling them would have been quite approved by his friends among the French poets. A more ambitious venture, the *Hous of Fame*, in which Chaucer imagines himself borne aloft by an eagle to Fame’s temple, describes what he sees and hears there, and then breaks off in apparent inability to get home, shows a curious mixture of the poetical ideals of the *Roman de la rose* and reminiscences of the *Divina Commedia*.

As the *Hous of Fame* is most often remembered and quoted for the personal touches and humour of Chaucer’s conversation with the eagle, so the most-quoted passages in the Prologue to the *Legende of Good Women* are those in which Chaucer professes his affection for the daisy, and the attack on his loyalty by Cupid and its defence by Alcest. Recent discoveries have shown, however, that (besides obligations to Machaut) some of the touches about the daisy and the controversy between the partitions of the Flower and of the Leaf are snatches from poems by his friends Froissart and Deschamps, which Chaucer takes up
and returns to them with pretty compliments, and that he was indebted to Froissart for some of the framework of his poem. Both of the two versions of the Prologue to the Legend of Good Women are charming, and some of the tales, notably that of Cleopatra, rank with Chaucer's best work. When, however, he had written eight and part of the ninth he tired of his scheme, which was planned to celebrate nineteen of Cupid's faithful "saints," with Alcestis as their queen. With his usual hopefulness he had overlooked the risk of monotony, which obviously weighed heavily on him ere he broke off, and the loss of the other ten stories is less to be regretted than that of the celebration of Alcestis, and a possible epilogue which might have been intended in the Prologue itself.

Chaucer's failure to complete the scheme of the Legend of Good Women may have been partly due to the attractions of the Canterbury Tales, which were probably taken up in immediate succession to it. His guardianship of two Kentish wards, his justiceship of the peace, his representing the county in the parliament of 1386, his commission of the river-bank between Greenwich and Woolwich, all make it easy to understand his dramatic use of the merry crowds he saw on the Canterbury road, without supposing him to have had recourse to Boccaccio's Decameron, a book which the reader may see for himself in each part of the Prologue. He imagines to have assembled at the Tabard Inn in Southwark, where Harry Bailey was host, are said to have numbered "we ney and twenty in a company," and the Prologue gives full-length sketches of a Knight, a Squire (his son), and their Yeoman; of a Prior, Monk, Friar, Oxford Clerk, and Parson, with two discrepant hangers-on of the church, a Summoner and Pardoner; of a Serjeant-at-Law and a Doctor of Physic, and of a Franklin, or country gentleman, Merchant, Shipman, Miller, Cook, Manciple, Reeve, Ploughman (the Parson's brother) and the ever-famous Wife of Bath. Five London burgesses are described in a group, and a Nun and Priest* are mentioned as in attendance on the Prioress. Each of these, with Chaucer himself making the twenty-ninth, was pledged to tell two tales, but including one second attempt and a tale told by the Yeoman of a Canon, who overacts the pilgrims on the road, we have only twenty finished stories, two unfinished and two interrupted ones. As in the case of the Legend of Good Women, our loss is not so much that of the additional stories as of the completed framework. The wonderful character sketches of the Prologue are carried yet farther by the Tales on the Road which link the different groups of these Tales, in which the Wife of Bath and the Pardoner respectively edify the company, have the importance of separate Tales, but between the Tales that have come down to us there are seven links missing, and it was left to a later and weaker hand to narrate, in the "Tale of Beryn," the adventures of the pilgrims at Canterbury.

The reference to the Lyf of Seynt Ceyce in the Prologue to the Legend of Good Women gives external proof that Chaucer included earlier work in the scheme of the Canterbury Tales, and mention has been made of other stories which are indisputably early. In the absence of any such metrical texts as have

1 The French influences on this Prologue, its connection with the Flower and the Leaf controversy, and the priority of what had previously been reckoned as the second or "B" form of the Prologue over the "A," were demonstrated in papers by Prof. Kittredge on "Chaucer and some of his Friends" in Modern Philology, vol. i. (Chicago, 1903), and by Mr. J. J. Lowes on "The Prologue to the Legend of Good Women" in Publications of the Modern Language Association of America, vol. x., December 1904.

2 The Talks on the Road show clearly that only one Priest in attendance, and a prisoner, as well as a number of other pilgrims having been condemned to 31 days' ride, and eight in nine tales a day would surely have been a sufficient allowance.

3 The absence of these links necessitates the division of the Canterbury Tales into nine groups, to which, for purposes of quotation, the letters A to I have been assigned, the line numeration of the Tales in each group being continuous.

proved useful in the case of Shakespeare, the dates at which several of the Tales were composed remain doubtful, while in the case of at least two, the Clerk's tale of Grisild and the Monk's tragedies, there is evidence of early work being revised and supplemented. It is fortunately impossible to separate the prologue to the charmingly told story of "yonge Hugh of Lincoln" from the tale itself, and with the "quod sche" in the second line as proof that Chaucer was here writing specially for his Prioress, we are forbidden to limit the new stories to any one metre or tone. There can be no doubt, however, that what may be the Tales of the Churis (Miller, Reeve, Summoner, Friar, &c.), and the conversational outpourings of the Pardoner and Wife of Bath, form, with the immortal Prologue, the most important and distinctive additions to the older work. In these, and in the Brother's story of Death and the Three Revellers, and the Nun's Priest's masterly handling of the fable of the Cock and Fox, both of them free from the grossness which marks the others, Chaucer takes stories which could have been told in a short page of prose and elaborates them with all the skill in narration which he had sedulously cultivated. The conjugal reminiscences of the Wife of Bath and the Reeve's Tale with its abominable climax (lightened a little by Aleyne's farewell, lines 316-319) are among the most characteristic of Chaucer, as surely as Stories, of the Pardoner and Arcyte and the Prologue. They help not only to give him the width of range which may certainly be claimed for him.

In or soon after 1391 Chaucer wrote in prose for an eleven-year-old reader, whom he addressed as "Lilet Lowis my son," a treatise on the use of the Astrolabe, its short prologue being the prettiest specimen of his prose. The wearisome tale of "Melibee and his wyf Prudence," which was perhaps as much admired in English as it had been in Latin and French, may have been translated at any time. The sermons on Penitence, used as the Parson's Tale, was probably the work of his old age. "Envoys" to his friends Scogan and Bleton, a translation of some balades by Sir Otes de Granson, and the Compleynt to his Pars complete the record of his minor poetry. We have his own statement that in his youth he had written many Balades, Roundels and Virelais in honour of Love, and the two songs embedded respectively in the Partem of Fourles and the Prologue to the Legend of Good Women are charming and musical. His extant shorter poems, however, whether early or late, offer no excuse for claiming high rank for him as a lyricist. He had been a little of a singing priest, and though there are fine lines in his short poems, we must say to the famous "File fro the prees and dwell with soothfastnesse," they lack the sustained concentration of great work. From the drama, again, Chaucer was cut off, and it is idle to argue from the inconsiderable dramatic touches in his poems and his gift of characterization as to what he might have done had he lived two centuries later. His own age delighted in stories, and he gave it the stories it demanded invested with a humanity, a grace and strength which place him among the world's greatest narrative poets, and which bring the England of his own day, with all the colour and warmth of life, wonderfully near to all his readers.

The part played by Chaucer in the development of the English language has often been overlooked. He neither corrupted it, as would otherwise have avoided, nor bore any such part in fixing it as was afterwards played by the translators of the Bible. When he was growing up educated society in England was still bilingual, and the changes in vocabulary and pronunciation which took place during his life were rather the result of a change in society, which had been bilingual with a bias towards French, giving an exclusive preference to English. The practical identity of Chaucer's language with that of Gower shows that both merely used the best English of their day with the care and slightly conservative tendency which befitted poets. Chaucer's service to the English language lies in his decisive success having made it impossible for any later English poet to assume the name, as Gower had, by writing alternatively in Latin and French. The claim which should be made for him is
that, at least as regards poetry, he proved that English was "sufficient."

Chaucer borrowed both his stanza forms and his "decalogue" of couplets (mostly with an extra syllable at the end of the line) from Guillaume Machault, and his music, like that of his French master and his successors, depends very largely on assigning to every syllable its full value, and more especially on the due pronunciation of the final -e. The slower movement of change in Scotland allowed time for Chaucer to exercise a potent influence on Scottish poetry, but in England this final -e, to which most of the earlier grammatical forms by Chaucer's time had been reduced, itself fell rapidly into disuse during the 15th century, and a serious barrier was thus raised to the appreciation of the artistic value of his verse. His disciples, Hoccleve and Lydgate, who at first had caught some echoes of his rhythms, gradually yielded to the change in pronunciation, so that there was no living tradition to hand down his secret, while successive copyists reduced his text to a state in which it was only by accident that lines could be scanned correctly. For fully three centuries his reputation was sustained solely by his narrative power, his warmest panegyrist betraying no consciousness that they were praising one of the greatest technical masters of poetry. Even when thus maligned, however, his works found readers and lovers in every generation, and every improvement in his text has set his name on a surer basis.

BIBLIOGRAPHY.—The Canterbury Tales have always been Chaucer's most popular work, and they include, under the cover of sixty 15th-century manuscripts of it still survive. Two thin volumes of his minor poems were among the little quarto which Caxton printed by way of advertisement immediately on his return to England, the Canterbury Tales (Bodleian 4, 1474), and the first edition of the Tales in 1482, the House of Fame in 1484. The Canterbury Tales were subsequently printed in 1492 (Pynson), 1493 (deworde) and 1526 (Pynson); Troilus in 1517 (de Wore) and 1526 (Pynson). The first two editions of the raw's in 1526 (Pynson) and 1530 (de Wore), and the Mars, Venus and Envy to Blakyn by Juliana Notary about 1500. Pynson's three issues in 1526 almost amounted to a collected edition, but the first of which the title the Horae of Godwin's Life-Records of Cantal, at the foot of the mountains of Aubrac, 19 m. S.S.W. of St Flour by road. Pop. (1906) town, 937; commune, 1848. It is celebrated for its hot mineral springs, which vary in temperature from 135³ to 179³ Fahr., and at their maximum rank as the hottest in France. The water, which contains bicarbonate of soda, is employed not only medicinally (for rheumatism, &c.), but also for the washing of fleeces, the incubation of eggs, and various other economic purposes; and it furnishes a ready means of heating the houses of the town during winter. In the immediate neighbourhood is the cold chalybeate spring of Condamine. The warm springs were known to the Romans, and are mentioned by Sidonius Apollinaris.

CHAUPEUR (from Fr. chaufer, to heat, a term primarily used in French of a man in charge of a forge or furnace, and so of a stoker on a locomotive or in a steamship, but in its anglicized sense more particularly confined to a professional driver of a motor vehicle. (See also BRIANDAGE.)

CHALILIE, GUILLAUME AMFRAVE DE (1659-1720), French poet and wit, was born at Fontenay, Normandy, in 1659. His father was a miller and left him in 1671 to be educated at the Collège de Navarre. Guillaume early showed the wit that was to distinguish him, and gained the favour of the duke of Vendôme, who procured for him the abbey of Aumale and other benefices. Louis Joseph, duke of Vendôme, and his brother Philippe, grand prior of the Knights of Malta in France, at that time had a joint establishment at the Temple, where they gathered round them a very gay and reckless circle. Chaulieu became the constant companion and adviser of the two princes. He made an expedition to Poland in the suite of the marquis de Béthune, hoping to make a career for himself in the court of John Sobieski; he saw one of the Polish king's campaigns in Ukraine, but returned to Paris without securing any advancement. Saint-Simon says that the abbé helped his patron the grand prior to rob the duke of Vendôme, and that the king sent orders that the princes should take the management of their affairs from him. This account has been questioned by Sainte-Beuve, who regards Saint-Simon as a prejudiced witness. In his later years Chaulieu spent much time at the little court of the duchesse de Maine at Sceaux. There he became the trusted and beloved friend of Mlle Chaulieu, the sister of the marquis de Beranger, Chaulieu's cousin, and also his biographer. Among his poems the best known are "Fontenay" and "La Retraite." Chaulieu died on the 27th of June 1726.

His works were edited with those of his friend the marquis de la Fare in 1714, 1750, and 1774. See also C. A. Sainte-Beuve, Causures du lendemain, vol. 1.; and Lettres intérieures (1850), with a notice by Raymond, marquis de Beranger.

CHAUMETTE, PIERRE GASPARD (1763-1794), French revolutionist, was born at Nevers. Until the Revolution he lived a somewhat wandering life, interesting himself particularly in botany. He was a student of medicine at Paris in 1790, became one of the orators of the club of the Cordeliers, and contributed anonymously to the Révolutions de Paris. As member of the insurrectionary Commune of the 19th of August 1792, he was delegated to visit the prisons, with full power to arrest suspects. He was accused later of having taken part in the massacres of September, but was able to prove that at that time he had been sent by the provisional executive council to Normandy to oversee a requisition of 60,000 men. Returning
from this mission, he pronounced an eloquent discourse in favour of the republic. His simple manners, easy temperament and irreproachable private life gave him great influence in Paris, and he was elected president of the Commune, defending the municipality in that capacity at the bar of the Convention on the 31st of October 1792. Re-elected in the municipal elections of the 2nd of December 1792, he was soon charged with the functions of procurator of the Commune, and contributed with success to the enrolments of volunteers by his appeals to the populace. Chaumette was one of the ringleaders in the attacks of the 31st of May and of the 2nd of June 1793 on the Girondists, toward whom he showed himself relentless. He demanded the formation of a revolutionary army, and preached the extermination of all traitors. He was one of the promoters of the worship of Reason, and on the 10th of November 1793 he presented the goddess to the Convention in the guise of an actress. On the 23rd of the same month he obtained a decree closing all the churches of Paris, and placing the priests under strict surveillance; but on the 25th he retreated his steps and obtained from the Commune the free exercise of worship. He was accused by the Girondists of a new insurrection and struggled against Robespierre; but a revolutionary decree promulgated by the Commune on his demand was overthrown by the Convention. Robespierre had him accused with the Hébertists; he was arrested, imprisoned in the Luxembourg, condemned by the Revolutionary tribunal and executed on the 13th of April 1794. Chaumette's career had its brighter side. He was an ardent social reformer; he secured the abolition of corporal punishment in the schools, the suppression of lotteries, of houses of ill-fame and of obscene literature; he instituted reforms in the hospitals, and insisted on the honours of public burial for the poor.

Chaumette left some printed speeches and fragments, and memoirs published in the Amour de l'antiquités. His memoirs on the 10th of August were published by F. A. Aulard, preceded by a biographical study.

CHAUMONT-EN-BASSIGNY—CHAUNCY

CHAUMONT-EN-BASSIGNY, a town of eastern France, capital of the department of Haute-Marne, a railway junction 163 m. E.S.E. of Paris on the main line of the Eastern railway to Belfort. Pop. (1906) 12,089. Chaumont is picturesquely situated on an eminence between the river Marne and Suize in the angle formed by their confluence. To the west a lofty viaduct over the Suize carries the railway. The church of St.-Jean-Baptiste dates from the 13th century, the choir and lateral chapels belonging to the 15th and 16th. In the interior the sculptured triforium (13th century), the spiral staircase in the transept and a Holy Sepulchre are of interest. The lycée and the hospital have chapels of the 17th and 16th centuries respectively. The Tour Hautefente (a keep of the 11th century) is the principal relic of a château of the counts of Champagne; the rest of the site is occupied by the law courts. In the Place de l'Escargot stands a statue of the chemist Philippe Lebon (1676-1804), born in Haute-Marne. Chaumont is the seat of a prefect and of a court of assizes, and has tribunals of first instance and of commerce, a lycée, training colleges, and a branch of the Bank of France. The main industries are glove-making and leather-dressing. The town has trade in grain, iron, mined in the vicinity, and leather. In 1705 it received a charter from the counts of Champagne, and in 1814 Great Britain, Austria, Russia and Prussia concluded the treaty of Chaumont (March 1, signed March 9) by which they severally bound themselves not to conclude a separate peace with Napoleon, and to continue the war until France should have been reduced within the boundaries of 1792.

CHAUNCEY, ISAAC (1772-1840), American naval commander, was born at Black Rock, Connecticut, on the 20th of February 1772. He was brought up in the merchant service, and entered the United States navy as a lieutenant in 1788. His first services were rendered against the Barbary pirates. During these operations, more especially at Tripoli, he greatly distinguished himself, and was voted by Congress a sword of honour, which, however, does not appear to have been given him. The most active period of his life is that of his command on the Lakes during the War of 1812. He took the command at Sackett's Harbor on Lake Ontario in October 1812. There was at that time only one American vessel, the brig "Oreada" (16), and one armed prize, a schooner, on the lake. But Commodore Chauncey brought from 400 to 500 officers and men with him, and local resources for building being abundant, he had by November formed a squadron of ten vessels, with which he attacked the Canadian port, York, taking it in April 1813, capturing one vessel and causing the destruction of another then building. He returned to Sackett's Harbor. In May Sir James Lucas Yeo (1732-1818) came out from England with some 500 officers and men, to organize a squadron for service on the Lakes. By the end of the month he was ready for service with a squadron of eight ships and brigs, and some small craft. The governor, Sir G. Prevost, gave him no serious support. On the 29th of May, during Chauncey's absence at Niagara, the Americans were attacked at Sackett's Harbor and would have been defeated if Prevost had not insisted on a reenact at the very moment when the American shipbuilding yard was in danger of being burnt, with a ship of more than eight hundred tons on the stocks. The retreat of the British forces was long drawn out, the "General Pike," which was so far superior to anything under Yeo's command that she was said to be equal in effective strength to the whole of the British flotilla. The American commodore was considered by many of his subordinates to have displayed excessive caution. In August he skirmished with Sir James Yeo's small squadron of six vessels, but made little effective use of his own fourteen. Two of his schooners were upset in a squall, with the loss of all hands, and he allowed two to be cut off by Yeo. Commodore Chauncey showed a preference for relying on his long guns, and a disinclination to come to close quarters. He was described as chasing the British squadron all round the lake, but his encounters did not go beyond artillery duels at long range, and he allowed his enemy to continue in existence long after he might have been destroyed. The winter suspended operations, and both sides made exertions to increase their forces. The Americans had the advantage of commanding greater resources for shipbuilding. Sir James Yeo began by blockading Sackett's Harbor in the early part of 1814, but when the American squadron was ready he was compelled to retire by the disparity of the forces. The American commodore was now able to blockade the British flotilla at Kingston. When the commercial season of the lake was nearly over he in his turn retired to Sackett's Harbor, and did not leave it for the rest of the war. During his later years he served as commissioner of the navy, and was president of the board of naval commissioners from 1833 till his death at Washington on the 27th of February 1840.

See Roosevelt's War of 1812 (1882); and A. T. Mahan, Sea-Power in its Relations to the War of 1812 (1905).

CHAUNCY, CHARLES (1592-1672), president of Harvard College, was born at Yardley-Bury, Hertfordshire, England, in November 1592, and was educated at Trinity College, Cambridge, of which he became a fellow. He was in turn vicar at Ware, Hertfordshire (1627-1633), and at Marston St Lawrence, Northamptonshire (1633-1637). Refusing to observe the ecclesiastical regulations of Archbishop Laud, he was brought before the high court of commission in 1639, and again in 1642, when, for opposing the placing of a royal proclamation table, he was suspended and imprisoned. His formal recantation in February 1657 caused him lasting self-reproach and humiliation. In 1657 he emigrated to America, and from 1658 until 1641 was an associate pastor at Plymouth, where, however, his advocacy of the baptism of infants by immersion caused dissatisfaction. He was the pastor at Scituate, Massachusetts, from 1641 until 1654, and from 1654 until his death was president of Harvard College, as the successor of the first president Henry Dunster (c. 1612-1659). He died on the 10th of February 1672. By his sermons and his writings he exerted a great influence in colonial Massachusetts, and according to Mather was "a most incomparable scholar." His writings include: The Plain Doctrine of the Justification of a Sinner in the Sight of God (1659) and Antisyonodalia Scripta Americana (1662). His son, Isaac
CHAUNY—CHAUVIN

CHAUNY (1632-1712), who removed to England, was a voluminous writer on theological subjects.

There are biographical sketches of President Chauncy in Cotton Mather's Magnalia Christi Americana (London, 1702), and in W. C. Fowler's Memorials of the Chauncys, including President Chauncy (Boston, 1859).

President Chauncy's great-grandson, CHARLES CHAUNCY (1705-1787), a prominent American theologian, was born in Boston, Massachusetts, on the 1st of January 1705, and graduated at Harvard in 1721. In 1727 he was chosen as the colleague of Thomas Foxcroft (1697-1765) in the pastorate of the First Church of Boston, continuing as pastor of this church until his death. At the time of the "Great Awakening" of 1740-1743 and afterwards, Chauncy was the leader of the so-called "Old Light" party in New England, which strongly condemned the Whitefieldian revival as an outbreak of emotional extravagance. His views were ably presented in his sermon Enthusiasm and in his Seasonable Thoughts on the State of Religion in New England (1743), written in answer to Jonathan Edwards's Some Thoughts Concerning the Present Revival of Religion in New England (1742). He also took a leading part in opposition to the projected establishment of an Anglican Episcopate in America, and before and during the American War of Independence he ardently supported the whig or patriot party. Theologically he has been classed as a precursor of the New England Unitarians. He died in Boston on the 10th of February 1787. His publications include: Complete View of Episcopacy, as Exhibited in the Fathers of the Christian Church, until the close of the Second Century (1771); Salvation of All Men, Illustrated and Vindicated as a Scripture Doctrine (1782); The Mystery Hid from Ages and Generations made manifest by the Gospel-Revolution (1783); and Five Dissertations on the Fall and its Consequences (1785).

See P. L. Ford's privately printed Bibliotheca Chaunciana (Brooklyn, N. Y., 1884); and Williston Walker's Ten New England Leaders (New York, 1901).

CHAUNY, a town of northern France in the department of Aisne, 19 m. S. by W. of St Quentin by rail. Pop. (1906) 10,126. The town is situated on the Oise (which here becomes navigable) and at the junction of the canal of St Quentin with the lateral canal of the Oise, and carries on an active trade. It contains mirror-polishing works, subsidiary to the mirror-works of St Gobain, chemical works, sugar manufactories, metal foundries and breweries. Chauncy was the scene of much fighting in the Hundred Years' War.

CHAUTAUQUA, a village on the west shore of Chautauqua Lake in the town of Chautauqua, Chautauqua county, New York, U.S.A. Pop. of the town (1900), 3500; (1905) 3505; (1910) 3515; of the village (1908) about 750. The lake is a beautiful body of water over 1300 ft. above sea-level, 20 m. long, and from a few hundred yards to 3 m. in width. The town of Chautauqua is situated near the north end and is within easy reach by steamboat and electric car connections with the main railways between the east and the west. The town is known almost solely as being the permanent home of the Chautauqua Institution, a system of popular education founded in 1875 by Lewis Miller (1829-1893), of Pymatuning, Ohio, and Bishop John H. Vincent (1836-1891). The village, covering about three hundred acres of land, is carefully laid out to provide for the work of the Institution.

The Chautauqua Institution began as a Sunday-School Normal Institute, and for nearly a quarter of a century the administration was in the hands of Mr Miller, who was responsible for the business management, and Bishop Vincent, who was head of the instruction department. Though founded by Methodists, in its earliest years it became non-sectarian and has furnished a meeting-ground for members of all sects and denominations. At the very outset the activities of the assembly were twofold: (1) the conducting of a summer school for Sunday-school teachers, and (2) the presentation of a series of correlated lectures and entertainments. Although the movement was and still is primarily religious, it has always been assumed that the best religious education must necessarily take advantage of the best that the educational world can afford in the literatures, arts and sciences. The scope of the plan rapidly broadened, and in 1879 a regular group of schools with graded courses of study was established. At about the same time, also, the Chautauqua Literary and Scientific Circle, providing a continuous home-reading system, was founded. The season lasts during June, July and August. In 1907 some 325 lectures, concerts, readings and entertainments were presented by a group of over 190 lecturers, readers and musicians, while at the same time 200 courses in the summer schools were offered by a faculty of instructors drawn from the leading colleges and normal schools of the country.

The Chautauqua movement has had an immense influence on education in the United States, an influence which is especially marked in three directions: (1) in the establishment of about 300 local assemblies or "Chautauquas" in the United States patterned after the mother Chautauqua; (2) in the promotion of the idea of summer education, which has been followed by the founding of summer schools or sessions at a large number of American universities, and of various special summer schools, such as the Catholic Summer School of America, with headquarters at Clif Haven, Clinton county, New York, and the Jewish Chautauqua Society, with headquarters at Buffalo, N.Y.; and (3) in the establishment of numerous correspondence schools patterned in a general way after the system provided by the Chautauqua Literary and Scientific Circle.

See John Heyl Vincent, The Chautauqua Movement (Boston, 1886), and Frank C. Bray, A Reading Journey through Chautauqua (Chicago, 1905).

CHAUVELIN, BERNARD FRANÇOIS, MARQUIS DE (1766-1832), French diplomatist and administrator. Though master of the king's wardrobe in 1780, he joined in the Revolution. He served in the army of Flanders, and then was sent to London in February 1792, to induce England to remain neutral in the war which was about to break out between France and "the king of Bohemia and Hungary." He was well received at first, but after the 10th of August 1792 he was no longer officially recognized at court, and on the execution of Louis XVI. (21st of January 1793) he was given eight days to leave England. After an unsuccessful embassy in Tuscany, he was imprisoned as a suspect during the Terror, but freed after the 9th Thermidor. Under Napoléon he became a member of the council of state, and from 1812 to 1814 he governed Catalonia under the title of intendant-general, being charged to win over the Catalonians to King Joseph Bonaparte. He remained in private life during the Restoration, and then went to the Duchy of Brunswick. In 1816 he was elected deputy, and spoke in favour of liberty of the press and extension of the franchise. Though he was again deputy in 1827 he played no part in public affairs, and resigned in 1829.

See G. Pallain, La Mission de Talleyrand à Londres en 1792 (Paris, 1889).

CHAUVIN, a town of western France, in the department of Vienne, 20 m. E. of Poitiers by rail. Pop. (1906) 2356. The town is finely situated overlooking the Vienne and a small torrent, and has two interesting Romanesque churches, both restored in modern times. There are also ruins of a château of the bishops of Poitiers, and of other strongholds. Near Chauvin is the curious bone-cavern of Jióux, the entrance to which is fortified by large blocks of stone. The town carries on lime-burning and plaster-manufacture, and there are stone quarries in the vicinity. Trade is in wool and feathers.

CHAUVIN, ÉTIENNE (1640-1725), French Protestant divine, was born at Nimes on the 18th of April 1640. At the revocation of the Edict of Nantes he retired to Rotterdam, where he was for some years preacher at the Walloon church; in 1665 the elector of Brandenburg appointed him pastor and professor of philosophy, and later inspector of the French college at Berlin, where he enjoyed considerable reputation as a representative of Cartesianism and as a student of physics. His principal work is a laborious Lexicon Rationale, sive Thesaurus Philosophicus (Rotterdam, 1692; new and enlarged edition, Leuwarden, 1713).
He also wrote Theses de Cognitione Del (1662), and started the Nouveau Journal des Savants (1694-1698).

CHAUVINISM, a term for unreasonable and exaggerated patriotism, the French equivalent of “Jingoism.” The word originally signified idolatry of Napoleon, being taken from a much-wounded veteran, Nicholas Chaunvi, who, by his adoration of the emperor, became the type of blind enthusiasm for national military glory.

CHAUZ DE FONDS, LA, a large industrial town in the Swiss canton of Neuchâtel. It is about 19 m. by rail N.W. of Neuchâtel, and stands at a height of about 3255 ft. in a valley (5 m. long) of the same name in the Jura. Pop. (1900) 3816 (only 13659 in 1850); (1905) 38700, mainly French-speaking and Protestant; of the 6114 “Catholics” the majority are “Old Catholics.” It is a centre of the watch-making industry, especially of gold watch cases; about 70% of those manufactured in Switzerland are turned out here. In 1900 it exported watches to the value of nearly £5,000,000 sterling. There is a school of industrial art (engraving and enamelling watch cases) and a school of watch-making (including instruction in the manufacture of chronometers and other watches, and the second half of the 18th century). It boasts of having le plus vaste village de l’Europe, and certainly has preserved some of the features of a big village. Léopold Robert (1794-1835), the painter, was born here. (W. A. C.).

CHAVES, a town of northern Portugal, in the district of Villa Real, formerly included in the province of Tras os Montes; 8 m. S. of the Spanish frontier, on the right bank of the river Tamega. Pop. (1900) 6388. Chaves is the ancient Aquea Flaviae, famous for its hot saline springs, which are still in use. It was a fine Roman bridge of 18 arches span the Tamega. In the 16th century Chaves contained 20,000 inhabitants; it was long one of the principal frontier fortresses, and in fact derives its present name from the position which makes it the “keys,” or chaves, of the north. One of its churches contains the tomb of Alphonso I. of Portugal (1139-1185). In 1380 the town gave the title of marquess to Pinto da Fonseca, a leader of the Miguelet party.

CHAZELLÉS, JEAN MATHIEU DE (1657-1710), French hydrographer, was born at Lyons on the 24th of July 1657. He was nominated professor of hydrography at Marseilles in 1689, and in that capacity carried out various coast surveys. In 1699 he published for the first time his Neptunus francensis, which was to include the hydrography of the Mediterranean. For this purpose he visited the Levant and Egypt. When in Egypt he measured the pyramids, and, finding that the angles formed by the sides of the largest were in the direction of the four cardinal points, he concluded that this position must have been intended, and also that the poles of the earth and meridians had not deviated since the erection of those structures. He was made a member of the Academy in 1695, and died in Paris on the 16th of January 1710.

CHEADLE, a town in the Altrincham parliamentary division of Cheshire, England, 6 m. S. of Manchester, included in the urban district of Cheadle and Gatley. Pop. (1901) 7916. This is one of the numerous townships of modern growth which fringe the southern boundaries of Manchester, and practically form suburbs of that city. Stockport lies immediately to the east. The name occurs in the formerly separate villages of Cheadle Hulme, Cheadle Bulkley and Cheadle Moseley. There are cotton printing and bleaching works in the locality. The parish church of St Giles, Cheadle, is Perpendicular, containing an altar-tomb of the 15th century for two knights.

CHEADE, a market town in the Leek parliamentary division of Staffordshire, England, 13 m. N.E. of Stafford, and the terminus of a branch line from Cresswell on the North Staffordshire railway. Pop. (1901) 5186. The Roman Catholic church of St Giles, with a lofty spire, was designed by Pugin and erected in 1846. The interior is lavishly decorated. There are considerable collieries in the neighbourhood, and silk and tape works in the town. In the neighbouring Froghall district limestone is quarried, and there are manufactures of copper. In Cheadle two fairs of ancient origin are held annually.

CHEATING, “the fraudulently obtaining the property of another by any deceitful practice not amounting to felony, which practice is of such a nature that it directly affects, or may directly affect, the public at large” (Stephen, Digest of Criminal Law, chap. x. § 5). Cheating is either a common law or statutory offence, and is punishable as a misdemeanour. An indictment for cheating at common law is of comparatively rare occurrence, and the statutory crime usually presents itself in the form of obtaining money by false pretences (q.v.). The word “cheat” is a variant of "escheat," i.e. the reversion of land to a lord of the fee through the failure of the blood of the tenant. The shortened form “cheater” for “escheator” is found early in the legal sense, and escheley appears in the Promptorium Parvorum, c. 1440, as the equivalent of confiscatio. In the 16th century “cheat” occurs in vocabularies of thieves and other slang, and in such works as the Use of Dice-Play (1532). It is frequent in Thomas Harman’s Caeanct or Warning for . . . Vagabones (1507), in the sense of “thing,” with a descriptive word attached, e.g. smuggling, etc." --nose. In the tract Mihl Munchance, his Discourse of the Art of Cheating, doubtfully attributed to Robert Greene (1560-1592), we find that gamesters call themselves cheaters, “borrowing the term from the lawyers.” The sense development is obscure, but it would seem to be due to the existence of a common legal practice, known as escheator, in which the legal escheator (the escheating officer) would seize on the property of a tenant, and claim it on behalf of the lord. The word is also used as a common noun for any wherein, such as escheating officer. In this sense, and the phrase escheat, are prominent in one or two humorous tales.

CHEBIEV, PAVUTNY LYOVIICH (1808-1882), a Russian mathematician, was born at Borovsk on the 26th of May 1821. He was educated at the university of Moscow, and in 1859 became professor of mathematics in the university of St Petersburg, a position from which he retired in 1880. He was chosen a correspondent of the Institute of France in 1860, and succeeded to the high honour of associé étranger in 1874. He was also a foreign member of the Royal Society of London. After N. I. Lobachevsky he probably ranks as the most distinguished mathematician Russia has produced. In 1841 he published a valuable paper, “Sur la convergence de la série de Taylor,” in Crelle’s Journal. His best-known papers, however, deal with prime numbers; in one of these (“Sur les nombres premiers,” 1850) he established the existence of limits within which must be comprised the sum of the logarithms of the primes inferior to a given number. Another question to which he devoted much attention was that of obtaining rectilinear motion by linkage. The parallel motion, known by his name is a three-bar linkage, which gives a very close approximation to rectilinear motion, but in spite of all his efforts he failed to devise one that produced absolutely true rectilinear motion. At last, indeed, he came to the conclusion that to do so was impossible, and in that conviction set to work to find a rigorous proof of the impossibility. While he was engaged on this task the desired linkage, which moved the highest admiration of J. J. Sylvester, was discovered and exhibited to him by one of his pupils, named Lipkin, who, however, it was afterwards found, had been anticipated by A. Peaucellier. Chebichev further constructed an instrument for drawing large circles, and an arithmetical machine with continuous motion. His mathematical writings, which account for some forty entries in the Royal Society’s catalogue of scientific papers, cover a wide range of subjects, such as the theory of probabilities, quadratic forms, theory of integrals, gearings, the construction of geographical maps, etc. He also published a Traité de la théorie des nombres. He died at St Petersburg on the 8th of December 1884.

CHEOBYGAN, or Chebogan county, Michigan, U.S.A., on South Channel (between Lakes Michigan and Huron), at the mouth of Chetoghan river, in the N. part of the lower peninsula. Pop. (1890) 6235; (1900) 6452, of whom 2101 were foreign-born; (1900) 6795; (1910) 6859. It is served by the Michigan Central and the Detroit & Mackinac railways, and by steamboat lines to Chicago, Milwaukee, Detroit, Sault Ste Marie, Green Bay and other lake ports; and is connected by ferry with Mackinac and Pointe aux Pins. During a great part of the year small boats ply between Cheboygan and the head of Crooked Lake, over the "Inland Route." Cheboygan is situated in a fertile farming region, for
which it is a trade centre, and it has lumber mills, tanneries, paper mills, boiler works, and other manufacturing establishments. The water-works are owned and operated by the municipality. The city, at first called Duncan, then Inverness, and finally Cheboygan, was settled in 1836, incorporated as a village in 1851, reincorporated in 1877, and chartered as a city in 1889.

CHECHENZES, Tchetchens, or Khists (Kosti), the last being the name by which they are known to the Georgians, a people of the eastern Caucasus occupying the whole of west Daghestan. They call themselves Nakhchtes, “people.” A wild, fierce people, they fought desperately against Russian aggression in the 18th century under Daud Beg and Oman Khan and Shamyl, and in the 19th under Khazi-Mollah, and even now some are independent in the mountain districts. On the surrender of the chieftain Shamyl to Russia in 1859 numbers of them migrated into Armenia. In physique the Chechenzes resemble the Circassians, and have the same haughtiness of carriage. They are of a generous temperament, very hospitable, but quick to revenge. They are fond of fine clothes, the women wearing rich robes with wide, pink silk trousers, silver bracelets and yellow sandals. Their houses, however, are mere hovels, some dug out of the ground, others formed of boughs and stone. Before their subjection to Russia they were remarkable for their independence of spirit and love of freedom. Everybody was equal, and they had no slaves except prisoners of war. Government in each village was by popular assembly, and the administration of justice was in the hands of the wronged. Murder and robbery with violence could be expiated only by death, unless the criminal allowed his hair to grow and the injured man consented to shave it himself and take an oath of brotherhood on the Koran. Otherwise the law of vendetta was fully carried out with curious details. The wronged man, wrapped in a white woollen shroud, and carrying a coin to serve as payment to a priest for saying the prayers for the dead, started out in search of his enemy. When the offender was found he must fight to a finish. A remarkable custom among one tribe is that if a betrothed man or woman dies on the eve of her wedding, the marriage ceremony is still performed, the dead being formally united to the living before witnesses, the father, in case it is the girl who dies, never failing to pay her dowry. The religion of the Chechenzes is Mahomedanism, mixed, however, with Christian doctrines and observances. Three churches near Kistin in honour of St George and the Virgin are visited as places of pilgrimage, and rams are there offered as sacrifices. The Chechenzes number upwards of 200,000. They speak a distinct language, and of the same race are some of the Bear and Cub dialects in east Caucasus. See Ernest C entityType="encyclopedia" id="1100101" title="Recherches anthropologiques dans le Caucase (Lyon, 1885-1887); D. G. Brion, Races of Man (1890); Hutchinson, Living Races of Mankind (London, 1901)."

CHECKERS, the name by which the game of draughts (q.v.) is known in America. The origin of the name is the same as that of "chess" (q.v.).

CHEDDAR, a small town in the Wells parliamentary division of Somersetshire, England, 22 m. S.W. of Bristol by a branch of the Great Western railway. Pop. (1901) 1795. The town, with its Perpendicular church and its picturesque market-cross, lies below the south-western face of the Mendip Hills, which rise sharply from 600 to 800 ft. To the west stretches the valley of the river Axe, broad, low and flat. A fine gorge opening from the hills immediately upon the site of the town is known as Cheddar cliffs from the sheer walls which flank it; the contrast of its rocks and rich vegetation, and the falls of a small stream traversing it, make up a beautiful scene admired by many travelling it. Several stalactitical caverns are also seen, and prehistoric British and Roman relics discovered in and near them are preserved in a small museum. The two caverns most frequently visited are called respectively Cox's and Gough's; in each, but especially in the first, is a remarkable collection of fantastic and beautiful stalactical forms. There are other caverns of greater extent but less beauty, but their extent is not completely explored. The remains discovered in the caves give evidence of British and Roman settlements at Cheddar (Catre, Chedore), which was a convenient trade centre. The manor of Cheddar was a royal demesne in Saxons times, and the witenage was held there in 966 and 968. It was granted by John in 1204 to Hugh, archdeacon of Wells, who sold it to the bishop of Bath and Wells in 1229, whose successors were overlords until 1553, when the bishop granted it to the king. It is now owned by the marquis of Bath. By a charter of 1231 extensive liberties in the manor of Cheddar were granted to Bishop Joceline, who by a charter of 1235 obtained the right to hold a weekly market and fair. By a charter of Edward III. (1337) Cheddar was removed from the king's forest of Mendip. The market was discontinued about 1690. Fairs are now held on the 4th of May and the 20th of October under the original grants. The name of Cheddar is given to a well-known species of cheese (see DAIRY), the manufacture of which began in the 17th century in the town and neighbourhood.

CHEDUBA, or MAN-AUNG, an island in the Bay of Bengal, situated 10 m. from the coast of Arakan, between 18° 40' and 18° 56' N. lat., and between 93° 31' and 93° 50' E. long. It forms part of the Kyaukpyu district of Arakan. It extends about 20 m. in length from N. to S., and 17 m. from E. to W., and its area of 220 sq. m. supports a population of 26,890 (in 1903). The channel between the island and the mainland is navigable for boats, but not for large vessels. The surface of the interior is chiefly diversified by hills and dale, and in the southern portion some of the heights exceed a thousand feet in elevation. There are various indications of former volcanic activity, and along the coast are earthy cones covered with green-sward, from which issue springs of muddy water emitting bubbles of gas. Copper, iron and silver ore have been discovered; but the island is chiefly noted for its petroleum wells, the oil derived from which is of excellent quality, and is extensively used in the composition of paint, as it preserves wood from the ravages of insects. Timber is not abundant, but the gamboge tree and the wood-oil tree are found of a good size. Tobacco, cotton, sugar-cane, hemp and indigo are grown, and the staple article is rice, which is of superior quality, and the chief article of export. The inhabitants of the island are mainly Maghs. Cheduba fell to the Burmese in the latter part of the 19th century. From them it was captured in 1824 by the British, whose possession of it was confirmed in 1826 by the treaty concluded with the Burmese at Yandabo.

CHEERING, the uttering or making of sounds encouraging, stimulating or exciting to action, indicating approval or acclaiming or welcoming persons, announcements of events and the like. The term is of ancient origin, a counterpart of the words "cheer" and "cheer up," which are of very early date, and the sense "encouraging, expressing encouragement, and came through the O. Fr. into M. Engl. in the 13th century from the Low Lat. cara, head; this is generally referred to the Gr. καρά. Cara is used by the 6th-century poet Flavius Cresconius Corippus, "Postquam venere verandam Caesaris ante caram" (In Laudem Justini Minoris). "Cheer" was at first qualified with epithets, both of joy and gladness and of sorrow; compare "She thanked Dyomede for all...his good chere" (Chaucer, Troilus) with "If they sing...tis with so dull a cheere" (Shakespeare, Sonnets, xcvi.). An early transference in meaning was to hospitality or entertainment, and hence to food and drink, "good cheer." The sense of a shout of encouragement or applause is a late use. Defoe (Captain Singleton) speaks of it as a sailor's word, and the meaning does not appear in Johnson. Of the different words or rather sounds that are used in cheering, "hurrah," though now generally looked on as the typical British form of cheer, is found in various forms in German, Scandinavian, Russian (urd), French (houra). It is probably onomatopoeic in origin; some connect it with such words as "hury," "whirr," "the meaning would then be "haste," to encourage speed or onset in battle. The English "hurrah" was preceded by "huzza," stated to be a sailor's word, and generally connected with "heee," to hoist, probably being one of the cries that sailors use when hauling or hoisting. The German hoch, seen in full in hoch lebe der Kaiser, &c., the French vive, Italian and Spanish viva, erina, are cries rather
of acclaimation than encouragement. The Japanese shout bansai became familiar during the Russo-Japanese War. In reports of parliamentary and other debates the insertion of "cheers" at any point in a speech indicates that approval was shown by members of the House by emphatic utterances of "hear hear." Cheering may be tumultuous, or it may be conducted rhythmically by prearrangement, as in the case of the "Hip-hip-hurrah" by way of introduction to a simultaneous "hurrah."

Rhythmic cheering has been developed to its greatest extent in America in the college yells, which may be regarded as a development of the primitive war-cry; this custom has no real analogue at English schools and universities, but the New Zealand football team in 1907 familiarized English crowds at their matches with a similar sort of war-cry adopted from the Maoris. In American schools and colleges there is usually one cheer for the institution as a whole and others for the different classes. The oldest and simplest are those of the New England colleges. The original yells of Harvard and Yale are identical in form, being composed of rak (abbreviation of hurrah) nine times repeated, shouted in unison with the name of the university at the end. The Yale cheer is given faster than that of Harvard. Many institutions have several different yells, a favourite variation being the name of the college shouted nine times in a slow and prolonged manner. The best known of these variations is the Yale cheer, partly taken from the Frogs of Aristophanes, which runs thus:

"Brekekekéx, ko-áx, ko-áx,
Brekekekéx, ko-áx, ko-áx,
Q-op, Q-op, parabalou,
Yale, Yale, Yale,
Rah, rah, rah, rah, rah, rah, rah, rah, rah, rah, rah, Yale! Yale! Yale!"

The regular cheer of Princeton is:

"H'ray, h'ray, h'ray, tiger,
Siss, boom, ah; Princeton!"

This is expanded into the "triple cheer":

"H'ray, h'ray, h'ray,
Tiger, tiger, tiger,
Siss, siss, siss,
Boon, boon, boon,
Ah, ah, ah,
Princeton, Princeton, Princeton!"

The "railroad cheer" is like the foregoing, but begun very slowly and broadly, and gradually accelerated to the end, which is enunciated as fast as possible. Many cheers are formed like that of Toronto University:

"Varsirý, varsirý,
V-a-r-s-i-t-y (spelled)
VARSIT-Y (spelled staccato)
Vár-sí-t-y,
Rah, rah, rah!"

Another variety of yell is illustrated by that of the School of Practical Science of Toronto University:

"Who are we? Can't you guess? We are from the S.P.S.!!"

The cheer of the United States Naval Academy is an imitation of a nautical syren. The Amherst cheer is:

"Amherst! Amherst! Amherst! Rah! Rah! Amherst! Rah! Rah!
Rah! Rah! Rah! Rah! Rah! Rah! Rah! Amherst!"

Besides the cheers of individual institutions there are some common to all, generally used to compliment some successful athlete or popular professor. One of the oldest examples of these personal cheers is:

"Who was George Washington? First in war, First in peace, First in the hearts of his countrymen."

followed by a stamping on the floor in the same rhythm.

College yells are used particularly at athletic contests. In any large college there are several leaders, chosen by the students, who stand in front and call for the different songs and cheers, directing with their arms in the fashion of an orchestral conductor. This cheering and singing form one of the distinctive features of inter-collegiate and scholastic athletic contests in America.

CHEESE (Lat. caseus), a solidified preparation from milk, the essential constituent of which is the proteinous or nitrogenous substance casein. All cheese contains in addition some proportion of fatty matter or butter, and in the more valuable varieties the butter present is often greater in amount than the casein. Cheese being thus a compound substance of no definite composition is found in commerce of many different varieties and qualities; and such qualities are generally recognized by the names of the localities in which they are manufactured. The principal distinctions arise from differences in the composition and condition of the milk operated upon, from variations in the method of preparation and curing, and from the use of the milk of other animals besides the cow, as, for example, the goat and the ewe, from the milk of both of which cheese is manufactured on a commercial scale. For details about different cheeses and cheese-making, see DAIRY.

CHEESE CLOTH, the name given to cloth, usually made from flax or tow yarns, of an open character, resembling a fine riddle or sieve, used for wrapping cheese. A finer quality and texture is made for women's gowns. A similar cloth is used for lineings in the upholstery trade, and for the ground of embroidery.

CHEETA (Chita), or HUNTING-LEOPARD (Cynaceltus jubatus, formerly known as Gueparda jubata), a member of the family Felidae, distinguished by its claws being only partially retractile (see Carnivora). The cheeta attains a length of 3 to 4 ft.; it is of a pale fulvous colour, marked with numerous spots of black on the upper surface and sides, and is nearly white beneath. The fur is somewhat crisp, altogether lacking the sleekness which characterizes the fur of the typical cats, and the tail is long and somewhat bushy at the extremity. In confinement the cheeta soon becomes fond of those who are kind to it, and gives evidence of its attachment in an open, dog-like manner. The cheeta is found throughout Africa and southern Asia, and has been employed for centuries in India and Persia in hunting antelopes and other game. According to Sir W. Jones, this mode of hunting originated with Hushing, king of Persia, 865 B.C., and afterwards became so popular that certain of the Mongol emperors were in the habit of being accompanied in their sporting expeditions by a thousand hunting leopards. In prosecuting this sport at the present day the cheeta is conveyed to the field in a low car without sides, hooded and chained like hunting-birds in Europe in the days of falconry. When a herd of deer or antelopes is seen, the car, which bears a close resemblance to the ordinary vehicle used by the peasants, is usually brought within 200 yds. of the game before the latter takes alarm; the cheeta is then let loose and the hood removed from its eyes. No sooner does it see the herd, than dropping from the car on the side remote from it, it approaches stealthily, making use of whatever means of concealment the nature of the ground permits, until observed, when making a few gigantic bounds, it generally arrives in the midst of the herd and brings down its victim with a stroke of its paw. The sportsman then approaches, draws off a bowl of the victim's blood, and puts it before the cheeta, which is again hooded and led back to the car. Should it not succeed in reaching the herd in the first few bounds, it makes no further effort to pursue, but retires seemingly dispirited to the car. In Africa the cheeta is only valued for its skin, which is worn by chiefs and other people of rank. It should be added that in India the name cheeta (chita) is applied also to the leopard.

CHEFFONIER, properly Chipponier, a piece of furniture differentiated from the sideboard by its smaller size and by the
enclosure of the whole of the front by doors. Its name (which comes from the French for a rag-gatherer) suggests that it was originally intended as a receptacle for odds and ends which had no place elsewhere, but it now usually serves the purpose of a sideboard. It is a remote and illegitimate descendant of the cabinet; it has rarely been elegant and never beautiful. It was one of the many curious developments of the mixed taste, at once cumbersome and bizarre, which prevailed in furniture during the Empire period in England. The earliest cheffoniers date from that time; they are usually of rosewood—the favourite timber of that moment; their “furniture” (the technical name for knobs, handles and escutcheons) was most commonly of brass, and there was very often a raised shelf with a pierced brass gallery at the back. The doors were often panelled and often edged with brass-beading, while the feet were pads or claws, or, in the choicer examples, sphinxes in gilded bronze. Cheffoniers are still made in England in cheap forms and in great number.

CHEH-KIANG, an eastern province of China, bounded N. by the province of Kiang-su, E. by the sea, S. by the province of Fu-kien, and W. by the provinces of Kiang-si and Kiang-nan. It occupies an area of about 36,000 sq. m. and contains a population of 11,800,000. With the exception of a small portion of the great delta plain, which extends across the frontier from the province of Kiang-si, and in which are situated the famous cities of Hu Chow, Ka-hing, Hang-chow, Shao-Sing and Ning-po, the province forms a portion of the Nan-shan of south-eastern China, and is hilly throughout. The Nan-shan ranges run through the centre of the province from south-west to north-east, and divide it into a northern portion, the greater part of which is drained by the Tsien-t'ang-kiang, and a southern portion which is chiefly occupied by the Ta-chi basin. The valleys enclosed between the mountain ranges are numerous, fertile, and for the most part of exquisite beauty. The hilly portion of the province furnishes large supplies of tea, and in the plain which extends along the coast, north of Ning-po, a great quantity of silk is produced. In minerals the province is poor. Coal and iron are occasionally met with, and traces of copper ore are to be found in places, but none of these minerals exists in sufficiently large deposits to make mining remunerative. The province, however, produces cotton, rice, ground-nuts, wheat, indigo, tallow and beans in abundance. The principal cities are Hang-chow, which is famed for the beauty of its surroundings, Ning-po, which has been frequented by foreign ships ever since the Portuguese visited it in the 16th century, and Wenchow. Opposite Ning-po, at a distance of about 50 m., lies the island of Chusan, the largest of a group bearing that general name. This island is 21 m. long, and about 50 m. in circumference. It is very mountainous, and is surrounded by numerous islands and islets. On its south side stands the walled town of Ting-hai, in front of which is the principal harbour. The population is returned as 50,000.

CHEKE, SIR JOHN (1514–1557), English classical scholar, was the son of Peter Cheke, esquire-bedell of Cambridge University. He was educated at St John's College, Cambridge, where he became fellow, and was one of the leaders of the principles of the Reformation. His learning gained him an election to the court from the king, and in 1540, on Henry VIII's foundation of the regius professorship, he was elected to the chair of Greek. Amongst his pupils at St John's were Lord Burghley, who married Cheke's sister Mary, and Roger Ascham, who in The Scholemaster gives Cheke the highest praise for scholarship and character. Together with Sir Thomas Smith, he introduced a new method of Greek pronunciation very similar to that commonly used in England in the 19th century. It was strenuously opposed in the University, where the continental method prevailed, and Bishop Gardiner, as chancellor, issued a decree against it (June 1542); but Cheke ultimately triumphed. On the 4th of July 1554, he was chosen as tutor to Prince Edward, and after his pupil's accession to the throne he continued his instructions. Cheke took a fairly active share in public life; he sat, as member for Bletchingley, for the parliaments of 1547 and 1552–1553; he was made provost of King's College, Cambridge (April 1, 1548), was one of the commissioners for visiting that university as well as Oxford and Eton, and was appointed with seven divines to draw up a body of laws for the government of the church. On the 11th of October 1553, he was knighted; in 1553 he was made one of the secretaries of state, and sworn of the privy council. His zeal for Protestantism induced him to follow the duke of Northumberland, and he filled the office of secretary of state for Lady Jane Grey during her nine days' reign. In consequence Mary threw him into the Tower (July 27, 1553), and confiscated his wealth. He was, however, released on the 13th of September 1554, and granted permission to travel abroad. He went first to Basel, then visited Italy, giving lectures in Greek at Padua, and finally settled at Strassburg, teaching Greek for his living. In the spring of 1556 he visited Brussels to see his wife; on his way back, between Brussels and Antwerp, he and Sir Peter Carew were treacherously seized (May 15) by order of Philip of Spain, hurried over to England, and imprisoned in the Tower. Cheke was visited by two priests and by Dr John Feckenham, dean of St Paul's, whom he had formerly tried to convert to Protestantism, and, terrified by a show of force, was hurried into the Church of Rome by Cardinal Pole. He was accused of two public recantations. Overcome with shame, he did not long survive, but died in London on the 13th of September 1557, carrying, as T. Fuller says (Church History), “God's pardon and all good men's pity along with him.” About 1547 Cheke married Mary, daughter of Richard Hill, sergeant of the wine-cellar to Henry VIII., and by her he had three sons. The descendants of one of these, Henry, known only for his translation of an Italian morality play Freewyl (Tragedio del Libro Arbitrio) by Nigri de Bassano, settled at Pyrgo in Essex.

Thomas Wilson, in the epistle prefixed to his translation of the Olyanthias of Demosthenes (1570), has a long and most interesting account of Cheke; in To the Gentlemen Students, prefixed to Robert Greene's Menaphon (1589), he calls him “the Exchequer of eloquence, Sir Iohn Cheke, a man of men, supernaturally traded in all tongues.” Many of Cheke's works are still in MS., some have been altogether lost. One of the most interesting from a historical point of view is the Hyst of Sedition how preuens it to a Communowity (1549), written on the occasion of Ket's rebellion, republished in 1556, 1576 and 1641, on the last occasion with a life of the author by Gerard Langbaine. Others are D. Joannis Chrysostomi homilias duae (1545), D. Joannis Chrysostomi de providentia Dei (1545), The Gospel according to St Matthew (translated, c. 1550; ed. James Goodwin, 1843), De obitu Marini Alciati (Leo, 1548); a two volume life of St Francis of Assisi, prefixed to the edition of Seraphin (1551), De pronuntiatione Graecae linguae (Basel, 1555). He also translated several Greek works, and lectured ad aulae hujus saeculi in Doctorum上学 upon Demosthenes.

His Life was written by John Strype (1821); additions by J. Gough Nicolas in Archaeologia (1860), xxxviii. 96, 127.

CHELLIAN, the name given by the French anthropologist G. de Mortillet to the first epoch of the Quaternary period when the earliest human remains are discoverable. The word is derived from the French town Chelles in the department of Seine-et-Marne. The climate of the Chelian epoch was warm and humid as evidenced by the wild growth of figs and laurels. The animals characteristic of the epoch are the Elephas antiquus, the rhinoceros, the cave-bear, the hippopotamus and the striped hyena. Man existed and belonged to the Neanderthal type. The implements characteristic of the period are flints chipped into leaf-shaped points and held in the hand when used. The drift-beds of St Glorien, in the department of Essonne (Seine), of Hoxne (Suffolk), and the detrital laterites of Madagascar, are considered by de Mortillet to be synchronous with the Chelian beds.

See Gabriel de Mortillet, Le Préhistorique (1900); Lord Avebury, Prehistoric Times (1900).

CHELFORD, FREDERICK THESSIER, 1ST BARON (1704–1785), lord chancellor of England, was the third son of Charles Thessier, and was born in London on the 15th of April 1704. His father, collector of customs at St Vincent's, was the son of a Saxon gentleman who had migrated to England and become secretary to Lord Rockingham, and was the brother of Sir Frederic Thesiger, naval A.D.C. to Nelson at Copenhagen. Young Frederic Thesiger was originally destined for a naval
CHELMSFORD—CHELSEA
career, and he served as a midshipman on board the "Cambrian" frigate in 1807 at the second bombardment of Copenhagen. His only surviving brother, however, died about this time, and he became entitled to succeed to a valuable estate in the West Indies, so it was decided that he should leave the navy and study law, with a view to practising in the West Indies and eventually managing his property in person. Another change of fortune, however, awaited him, for a volcano destroyed the family estate, and he was thrown back upon his prospect of a legal practice in the West Indies. He proceeded to enter at Gray's Inn in 1813, and was called on the 18th of November 1818, another change in his prospects being brought about by the strong advice of Godfrey Sykes, a special pleader in whose chambers he had been a pupil, that he should remain to try his fortune in England. He accordingly joined the home circuit, and soon got into good practice at the Surrey sessions, while he also made a fortunate purchase in buying the right to appear in the old palace court (see Lord Steward). In 1824 he distinguished himself by his defence of Joseph Hunt when on his trial at Hertford with John Thurtell for the murder of Wm. Weare; and eight years later at Chelmsford assizes he won a hard-fought action in an ejectment case after three trials, to which he attributed so much of his subsequent success that where he was called on to defend a peer he always referred to Lord Chelmsford.
In 1834 he was made king's counsel, and in 1835 was briefly in the Dublin election inquiry which unseated Daniel O'Connell. In 1840 he was elected M.P. for Woodstock. In 1844 he became solicitor-general, but having ceased to enjoy the favour of the duke of Marlborough, lost his seat for Woodstock and had to find another at Abingdon. In 1845 he became attorney-general, holding the post until the fall of the Peel administration on the 3rd of July 1846. Thus by three days Theisger missed being chief justice of the common pleas, for on the 6th of July Sir Nicholas Tindal died, and the seat on the bench, which would have been Theisger's as of right, fell to the Liberal attorney-general, Sir Thomas Wilde. Sir Frederic Theisger remained in parliament, changing his seat, however, again in 1852, and becoming member for Stanmore. During this period he enjoyed a very large practice at the bar, being employed in many causes célèbres. On Lord Derby coming into office for the second time in 1858, Sir Frederic Theisger was raised straight from the bar to the lord chancellory (as Lord Chelmsford) in 1866, and Lord Derby resigned his cabinet was broken up. Again in 1866, on Lord Derby coming into office for the third time, Lord Chelmsford became lord chancellor for a short period. In 1868 Lord Derby retired, and Disraeli, who took his place as prime minister, wished for Lord Cairns as lord chancellor. Lord Chelmsford was very sore at his supersession and the manner of it, but, according to Lord Malmesbury he retired under a compact made before he took office. Ten years later Lord Chelmsford died in London on the 5th of October 1878. Lord Chelmsford had married in 1822 Anna Maria Tinling. He left four sons and three daughters, of whom the eldest, Frederick Augustus, 2nd Baron Chelmsford (1827–1905), earned distinction as a soldier, while the third, Alfred Henry Theisger (1838–1880) was made a lord justice of appeal and a privy councillor in 1877, at the early age of thirty-nine, but died only three years later. See Lives of the Chancellors (1908), by J. A. Atlay, who has had the advantage of access to an unpublished autobiography of Lord Chelmsford's.

CHELMSFORD, a market town and municipal borough, and the county town of Essex, England, in the Chelmsford parliamentary division, 30 m. E.N.E. from London by the Great Eastern railway. Pop. (1901) 12,580. It is situated in the valley of the Chelmer, at the confluence of the Cann, and has communication by the river with Maldon and the Blackwater estuary 11 m. east. Besides the parish church of St Mary, a graceful Perpendicular edifice, largely rebuilt, the town has a grammar school founded by Edward VI., an endowed charity school and a museum. It is the seat of the county assizes and quarter sessions, and has a handsome shire hall; the county gaol

is near the town. Its corn and cattle markets are among the largest in the county; for the first a fine exchange is provided. In the centre of the square in which the corn exchange is situated stands a bronze statue of Lord Chief Justice Tindal (1776–1846), a native of the parish. There are agricultural implement and iron foundries, large electric light and engineering works, breweries, tanneries, maltings and extensive corn mills. There is a race-course 2 m. south of the town. The borough is under a mayor, 6 aldermen and 18 councillors. Area 2,568 acres.

A place of settlement since Palaeolithic times, Chelmsford (Chelmersford, Chelmerford, Chelmsfords) owed its importance to its posi on on the road from London to Colchester. It consisted of two manors: that of Moulsham, which remained in the possession of Westminster Abbey from Saxon times till the reign of Henry VIII., when it was granted to Thomas Mildmay; and that of Bishop's Hall, which was held by the bishops of London from the reign of Edward the Confessor to 1545, when it passed to the crown and was granted to Thomas Mildmay in 1563. The medieval history of Chelmsford centred round the manor of Bishop's Hall. Early in the 12th century Bishop Maurice built the bridge over the Chelmer which brought the road from London directly through the town, thus making it an important stopping-place. The town was not incorporated until 1888. In 1225 John of England, who was a justice of the peace for the county of Chelmsford, deposed the bishop of London for the county of Essex, and in 1227 it became the regular seat of assizes and quarter-sessions. Edward I. confirmed Bishop Richard de Gravesend in his rights of frank pledge in Chelmsford in 1290, and in 1305 Richard II. granted the return of writs to Bishop Robert de Braybrooke. In 1377 writs were issued for the return of representatives from Chelmsford to parliament, but no return of members has been found. In 1199 the bishop obtained the grant of a weekly market at the yearly rent of one palfrey, and in 1201 that of an annual fair, now discontinued, for four days from the feast of St Philip and St James.

CHELSEA, a western metropolitan borough of London, England, bounded E. by the city of Westminster, N.W. by Kensington, S.W. by Fulham, and S. by the river Thames. Pop. (1901) 73,842. Its chief thoroughfare is Sloane Street, containing handsome houses and good shops, running south from Knightsbridge to Sloane Square. Hence King's Road leads west, a wholly commercial highway, named in honour of Charles II., and recalling the king's private road from St James's Palace to Chelsea, which was maintained until the reign of George IV. The main roads south communicate with the Victoria or Chelsea, Albert and Battersea bridges over the Thames. The beautiful Chelsea embankment, planted with trees and lined with fine houses and, in part, with public gardens, stretches between Victoria and Battersea bridges. The better residential portion of Chelsea is the eastern, near Sloane Street and along the river; the western, extending north to Fulham Road, is mainly a poor quarter.

Chelsea, especially the riverside district, abounds in historical associations. At Caeclwthyn a synod was held in 785. A similar name occurs in a Saxon charter of the 11th century and in Domesday; in the 16th century it is Chelcith. The later termination ey or ea was associated with the insular character of the land, and the prefix with a gravel bank (ceosal; cf. Cheshill Bank, Dorsetshire) thrown up by the river; but the early suffix hythe is common in the meaning of a haven. The manor was originally in the possession of Westminster Abbey, but its history is fragmentary until Tudor times. It then came into the hands of Henry VIII., passed from him to his wife Catherine Parr, and thereafter from her to whom it was the Howards, to whom it was granted by Queen Elizabeth, and the Cheynes, from whom it was purchased in 1712 by Sir Hans Sloane, after which it passed to the Cadogans. The memorials which crowd the picturesque church and churchyard of St Luke near the river, commonly known as the Old Church, to a great extent epitomize the history of Chelsea. Such are those of Sir Thomas More (d. 1532); Lord Bray, lord of the manor (1539), his father and son; Lady Jane Gyldeford, duchess of Northumberland, who died “at her maner of Chelse”
CHELSEA—CHELTEMHAM

in 1555; Lord and Lady Dacre (1594–1595); Sir John Lawrence (1638), Lady Jane Cheyne (1668); Francis Thomas, "director of the china porcelain manufactory, Lawrence Street, Chelsea" (1720); Sir Hans Sloane (1753); Thomas Shadwell, poet laureate (1692); Woodfall the printer of Junius (1844), and many others. More's tomb is dated 1532, as he set it up himself, though it is doubtful whether he lies beneath it. His house was near the present Beaufort Street. In the 18th and 19th centuries Chelsea, especially the parts about the embankment and Cheyne Walk, was the home of many eminent men, particularly of writers and artists, with whom this pleasant quarter has long been in favour. Thus in the earlier part of the period named, Atterbury and Swift lived in Church Lane, Steele and Smollett in Monmouth House. Later, the names of Turner, Rossetti, Whistler, Leigh Hunt, Carlyle (whose house in Cheyne Row is preserved as a public memorial), Count D'Orsay, and Isambard Brunel, are intimately connected with Chelsea. At Lindsey House Count Zinzendorf established a Moravian Society (c. 1750). Sir Robert Walpole's residence was extant till 1810; and till 1824 the bishops of Winchester had a palace in Cheyne Walk. Queen's House, the home of D. G. Rossetti, in Cheyne Row, was built by Sir John Soane for Catherine of Braganza.

Chelsea was noted at different periods for two famous places of entertainment, Ranelagh (q.v.) in the second half of the 18th century, and Cremorne Gardens (q.v.) in the middle of the 19th. Don Saltero's museum, which formed the attraction of a popular coffee-house, was formed of curiosities from Sir Hans Sloane's famous collections. It was Sloane who gave to the Apothecaries' Company the ground which they had leased in 1673 for the Physick Garden, which is still extant, but ceased in 1902 to be maintained by the Company. At Chelsea Sir John Danvers (d. 1655) introduced the Italian style of gardening which was so greatly admired by Bacon and soon after became prevalent in England. Chelsea was formerly famous for a manufacture of buns; the original Chelsea bun-house, claiming royal patronage, stood until 1839, and one of its successors until 1888. The porcelain works existed for some 25 years before 1769, when they were sold and removed to Derby. Examples of the original Chelsea ware (see Ceramics) are of great value.

Of buildings and institutions the most notable is Chelsea Royal Hospital for invalid soldiers, initiated by Charles II (according to tradition on the suggestion of Nell Gwynne), and opened in 1694. The hospital itself accommodates upwards of 500 men, but a system of out-pensioning was found necessary from the outset, and now relieves large numbers throughout the empire. The picturesque building by Wren stands in extensive grounds, which include the former Ranelagh Gardens. A theological college (King James's) formerly occupied the site; it was founded in 1610 and was intended to be of great size, but the scheme was unsuccessful, and only a small part of the buildings was erected. In the vicinity are the Chelsea Barracks (not actually in the borough). The Royal Military Asylum for boys, commonly called the Duke of York's school, founded in 1801 by Frederick, duke of York, for the education of children connected with the army, was removed in 1909 to new quarters at Dover. Other institutions are the Whitelands training college for school-mistresses, in which Ruskin took deep interest; the Sir Mark's college for school-mistresses in Victoria and the Cheyne hospitals for children, a cancer hospital, the South-western polytechnic, and a public library containing an excellent collection relative to local history.

The parliamentary borough of Chelsea returns one member, and includes, as a detached portion, Kensal Town, north of Kensington. The borough council consists of a mayor, 6 aldermen and 36 councillors. Area, 639-6 acres. CHELSEA, a city of Suffolk county, Massachusetts, U.S.A., a suburb of Boston. Pop. (1890) 27,900; (1900) 34,072, of whom 11,203 were foreign-born; (1910) 32,452. It is situated on a peninsula between the Mystic and Chelsea rivers, and Charlestown and East Boston, and is connected with East Boston and Charlestown by bridges. It is served by the Boston & Maine and (for freight) by the Boston & Albany railways. The United States maintains here naval and marine hospitals, and the state a soldiers' home. Chelsea's interests are primarily industrial. The value of the city's factory products in 1905 was $13,879,150, the principal items being rubber and elastic goods ($3,035,211) and boots and shoes ($2,044,250). The manufacture of stores, and of mucilage and paste, is important industries. Flexible tubing for electric wires (first made at Chelsea 1889) and art tiles are important products. The first settlement was established in 1624 by Samuel Maverick (c. 1602–c. 1670), the first settler (about 1629) of Noddle's Island (or East Boston), and one of the first slave-holders in Massachusetts; a loyalist and Churchman, in 1664 he was appointed with three others by Charles II. on an important commission sent to Massachusetts and the other New England colonies (see Nicolls, Richard), and spent the last years of his life in New York. Until 1730, under the name of Winnsimmet, Chelsea formed a part of Boston, but in that year it was made a township; it became a city in 1857. In May 1775 a British schooner in the Mystic defended by a force of marines was taken by colonial militia under General John Stark and Israel Putnam—"the first conflicts of the War of Independence." A terrible fire swept the central part of the city on the 12th of April 1908.

See Mellen Chamberlain (and others), History of Chelsea (2 vols., Boston, 1908), published by the Massachusetts Historical Society.

CHELTENHAM, a municipal and parliamentary borough of Gloucestershire, England, 109 m. W. by N. of London by the Great Western railway; served also by the west and north line of the Midland railway. Pop. (1901) 49,439. The town is well situated in the valley of the Chelt, a small tributary of the Severn, under the high line of the Cotswold Hills to the east, and is in high repute as a health resort. Mineral springs were accidentally discovered in 1716. The Montpellier and Pittville Springs supply handsome pump rooms standing in public gardens, and are the property of the corporation. The Montpellier waters are sulphated, and are valuable for their diuretic effect, and as a stimulant to the liver and alimentary canal. The alkaline-saline waters of Pittville are efficacious against diseases resulting from excess of uric acid. The parish church of St Mary dates from the 14th century, but is almost completely modernized. The town, moreover, is wholly modern in appearance. Assembly rooms opened in 1815 by the duke of Wellington were removed in 1901. A new town hall, including a central spa and assembly rooms, was opened in 1903. There are numerous other handsome buildings, especially in High Street, and the Promenade forms a beautiful broad thoroughfare, lined with trees. The town is famous as an educational centre. Cheltenham College (1842) provides education for boys in three departments, classical, military and commercial; and includes a preparatory school. The Ladies' College (1834), long conducted by Miss Beale (q.v.), is one of the most successful in England. The Normal Training College was founded in 1846 for the training of teachers, male and female, in national and parochial schools. A free grammar school was founded in 1568 by Richard Pate, rector of Gloucester. The art gallery and museum may be mentioned also. The parliamentary borough returns one member. The municipal borough is under a mayor, 6 aldermen and 50 councillors. Area, 4726 acres. The urban district of Charlton Kings (pop. 3806) forms a south-eastern suburb of Cheltenham.

The site of a British village and burying-ground, Cheltenham (Celtanhomme, Chilhham, Cheltham) was a village with a church in 803. The manor belonged to the crown; it was granted to Henry de Bohun, earl of Hereford, late in the 12th century, but in 1199 was exchanged for other lands with the king. It was granted to William de Longespé, earl of Salisbury, in 1219, but resumed on his death and granted in dower to Eleanor of Provence in 1243. In 1257 the abbey of Fécamp purchased the manor, and it afterwards belonged to the priory of Corrèze, but was confiscated in 1415 as the possession of an alien priory, and was granted in 1461 to the abbey of Lyon, by which it was held until, once more returning to the crown at the Dissolution,
CHELYABINSK—CHEMICAL ACTION

it was granted to the family of Dutton. The town is first mentioned in 1223, when William de Longespee leased the benefit of the markets, fairs, and hundred of Cheltenham to the men of the town for three years; the lease was renewed by Henry III. in 1226, and again in 1230 for ten years. A market town in the time of Camden, it was governed by commissioners from the 18th century in 1786, when it was incorporated; it became a parliamentary borough in 1832. Henry III. in 1230 had granted to the men of Cheltenham a market on each Thursday, and a fair on the vigil, feast and morrow of St. James. Although Camden mentions a considerable trade in malt, the spinning of woollen yarn was the only industry in 1779. After the discovery of springs in 1776, and the erection of a pump-room in 1788, Cheltenham rapidly became fashionable, the visit of George III. and the royal princesses in 1788 ensuring its popularity.

See S. Moreau, _A Tour to Cheltenham Spa_ (Bath, 1738).

CHELYABINSK, a town of Russia, in the Orenburg government, at the east foot of the Ural, is the head of the Siberian railway, 624 m. by rail E.N.E. of Samara and 154 m. by rail S.S.E. of Ekaterinburg. Pop. (1900) 25,505. It has tanneries and distilleries, and is the centre of the trade in corn and pasture fodder for the Ural iron-works. The town was founded in 1668.

CHELYS (Gr. χλῆς, tortoise; Lat. testudo), the common lyre of the ancient Greeks, which had a convex back of tortoiseshell or of wood shaped like the shell. The word chelys was used in allusion to the oldest lyre of the Greeks which was said to have been invented by Hermes. According to tradition he was attracted by sounds of music while walking on the banks of the Nile, and found they proceeded from the shell of a tortoise across which were stretched tendons which the wind had set in vibration (Homer. _Hymn to Hermes_, 47–51). The word has been applied arbitrarily since classic times to various strung instruments, some bowed and some twanged, probably owing to the back being much vacated. Kircher (_Musurgia_, 1, 486) applied the name of chelys to a kind of violin with eight strings. Numerous representations of the chelys lyre or testudo occur on the Greek vases, in which the actual tortoise is depicted; a good illustration is given in _La Antiquité de l’Ecole_ (vol. i, pl. 43). Proportions (iv. 6) calls the instrument the lyra testudinaria. Scaliger (on Manilius, _Astronomicon_, Proleg. 420) was probably the first writer to draw attention to the difference between chelys and cithara (_q.v._). (K. S.)

CHEMICAL ACTION, the term given to any process in which change in chemical composition occurs. Such processes may be set up by the application of some form of energy (heat, light, electricity, &c.) to a substance, or by the mixing of two or more substances together. If two or more substances be mixed one of three things may occur. First, the particles may be mechanically intermingled, the degree of association being dependent upon the fineness of the particles, &c. Secondly, the substances may intermolecularly penetrate, as in the case of gas-mixtures and solutions. Or thirdly they may react chemically. The question whether, in any given case, we have to deal with a physical mixture or a chemical compound is often decided by the occurrence of very striking phenomena. To take a simple example, water and hydrogen are two gases which may be mixed in all proportions at ordinary temperatures, and it is easy to show that the properties of the products are simply those of mixtures of the two free gases. If, however, an electric spark be passed through the mixtures, powerful chemical union ensues, with its concomitants, great evolution of heat and consequent rise of temperature, and a compound, water, is formed which presents physical and chemical properties entirely different from those of its constituents.

In general, powerful chemical forces give rise to the evolution of large quantities of heat, and the properties of the resulting substance differ vastly more from those of its components than is the case with simple mixtures. This constitutes a valuable criterion as to whether mere mixture is involved on the one hand, or strong chemical union on the other. When, however, the chemical forces are weak and the reaction, being incomplete, leads to a state of chemical equilibrium, in which all the reacting substances are present side by side, this criterion vanishes. For example, the question whether a salt combines with water molecules when dissolved in water cannot be said even yet to be fully settled, and, although there can be no doubt that solution is, in many cases, attended by chemical processes, still we possess as yet no means of deciding, with certainty, how many molecules of water have bound themselves to a single molecule of the dissolved substance (_solution_). On the other hand, we possess exact methods of testing whether gases or solutes in dilute solution react one with another and of determining the equilibrium state which is attained. For if one solute react with another on adding the latter to its solution, then corresponding to the decrease of its concentration there must also be a decrease of vapour pressure, and of solubility in other solvents; further, in the case of a mixture of gases, the concentration of each single constituent follows from its solubility in some suitable solvent. We thus obtain the answer to the question: whether the concentration of a certain constituent has decreased during mixing, i.e. whether it has reacted chemically.

When a compound can be obtained in a pure state, analysis affords us an important criterion of its chemical nature, for unlike mixtures, the compositions of which are always variable within wider or narrower limits, chemical compounds present definite and characteristic mass-relations, which find full expression in the atomic theory propounded by Dalton (see Atom). According to this theory a mixture is the result of the mutual interpenetration of the molecules of substances, which remain unchanged as such, whilst chemical union involves changes more deeply seated, inasmuch as new molecular species appear. These new substances, if well-defined chemical compounds, have a perfectly definite composition and contain a definite, generally small, number of elementary atoms, and therefore the law of constant proportions follows at once, and the fact that only an integral number of atoms of any element may enter into the composition of any molecule determines the law of multiple proportions.

The considerations bring us face to face with the task of more closely investigating the nature of chemical forces, in other words, of answering the question: what forces guide the atoms in the formation of a new molecular species? This problem is still far from being completely answered, so that a few general remarks must suffice here.

It is remarkable that among the most stable chemical compounds, we find combinations of atoms of one and the same element. Thus, the stability of the di-atomic molecule N₂ is so great, that no trace of dissociation has yet been proved even at the highest temperatures, and as the constituent atoms of the molecule N₂ must be regarded as absolutely identical, it is clear that "polar" forces cannot be the cause of all chemical action. On the other hand, especially powerful affinities are also at work when so-called electro-positive and electro-negative elements react. The forces which here come into play appear to be considerably greater than those just mentioned; for instance, potassium fluoride is perhaps the most stable of all known compounds of fluorine.

It is also to be noticed that the combinations of the electro-negative elements (metaloids) with one another exhibit a metalloid character, and also we find, in the mutual combinations of metals, all the characteristics of the metallic state; but in the formation of a salt from a metal and a metalloid we have an entirely new substance, quite different from its components; and at the same time, the product is seen to be an electrolyte, i.e. to have the power of splitting up into a positively and a negatively charged constituent when dissolved in some solvent. These considerations lead to the conviction that forces of a "polar" origin play an important part here, and indeed we may make the general surmise that in the act of chemical combination forces of both a non-polar and polar nature play a part, and that the latter are in all probability identical with the electric forces. It now remains to be asked—what are the laws which govern
the action of these forces? This question is of fundamental importance, since it leads directly to those laws which regulate the chemical process. Besides the already mentioned fundamental law of chemical combination, that of constant and multiple proportions, there is the law of chemical mass-action, discovered by Guldberg and Waage in 1867, which we will now develop from a kinetic standpoint.

**Kinetic Basis of the Law of Chemical Mass-action.**—We will assume that the molecular species \( A_1, A_2, \ldots A'_1, A'_2, \ldots \) are present in a homogeneous system, where they can react on each other only according to the scheme

\[
A_1 + A_2 + \ldots = A'_1 + A'_2 + \ldots
\]

This is a special case of the general equation

\[
nA_1 + nA_2 + \ldots = nA'_1 + nA'_2 + \ldots
\]

in which only one molecule of each substance takes part in the reaction. The reacting substances may be either gaseous or form a liquid mixture, or they dissolved in some selected solvent; but in each case we may state the following considerations regarding the course of the reaction. For a transformation to take place from left to right in the sense of the reaction equation, all the molecules \( A_1, A_2, \ldots \) must collide at one point; otherwise no reaction is possible, since we shall not consider side-reactions. Such a collision need not of course bring about that transposition of the atoms of the single molecules which constitutes the above reaction. Much rather must it be of such a kind as is favourable to that loosening of the bonds that bind the atoms in the separate molecules, which must precede this transposition. Of a large number of such collisions, therefore, only a certain smaller number will involve a transposition from left to right in the sense of the equation. But this number will be the same under the same external conditions, and the greater the more numerous the collisions; in fact a direct ratio must exist between the two. Bearing in mind now, that the number of collisions must be proportional to each of the concentrations of the bodies \( A_1, A_2, \ldots \), and therefore, on the whole, to the product of all these concentrations, we arrive at the conclusion that the velocity \( v \) of the transposition from left to right in the sense of the reaction equation is \( v = k_0c_1c_2 \ldots \), in which \( c_1, c_2, \ldots \) represent the spatial concentrations, i.e. the number of gram-molecules of the substances \( A_1, A_2, \ldots \) present in one litre, and \( k_0 \) is, at a given temperature, a constant which may be called the velocity-coefficient.

Exactly the same consideration applies to the molecules \( A'_1, A'_2, \ldots \). Here the velocity of the change from right to left in the sense of the reaction-equation increases with the number of collisions of all these molecules at one point, and this is proportional to the product of all the concentrations. If \( k' \) denotes the corresponding proportionality-factor, then the velocity \( v' \) of the change from right to left in the sense of the reaction-equation is

\[
v' = k'c'_1c'_2 \ldots \]

These spatial concentrations are often called the "active masses" of the reacting components. Hence the reaction-velocity in the sense of the reaction-equation from left to right, or the reverse, is proportional to the product of the "active-masses" of the left-hand or right-hand components respectively.

Neither \( v \) nor \( v' \) can be separately investigated, and the measurements of the course of a reaction always furnish only the difference of these two quantities. The reaction-velocity actually observed represents the difference of these two partial reaction-velocities, whilst the amount of change observed during any period of time is equal to the change in the one direction, minus the change in the opposite direction. It must not be assumed, however, that on the attainment of equilibrium all action has ceased, but rather that the velocity of change in one direction has become equal to that in the opposite direction, with the result that no further total change can be observed, i.e. the system has reached equilibrium, for which the relation \( v = v' = 0 \) must therefore hold, or what is the same thing

\[
k_0c_1c_2 \ldots = k'c'_1c'_2 \ldots
\]

This is the fundamental law of chemical statics.

The conception that the equilibrium is not to be attributed to absolute indifference between the reacting bodies, but that these continue to exert their mutual actions unchanged and the opposing changes now balance, is of fundamental significance in the interpretation of changes of matter in general. This is generally expressed in the form: the equilibrium in this and other analogous cases is not static but dynamic. This conception was a direct result of the kinetic-molecular considerations, and was applied with special success to the development of the kinetic theory of gases. Thus with Clausius, we conceive the equilibrium of water-vapour with water, not as if neither water vaporized nor vapour condensed, but rather as though the two processes went on unhindered in the equilibrium state, i.e. during contact of saturated vapour with water, in a given time, as many water molecules passed through the water surface in one direction as in the opposite direction. This view, as applied to chemical changes, was first advanced by A. W. Williamson (1831), and further developed by C. M. Guldberg and P. Waage and others.

From the previous considerations it follows that the reaction-velocity at every moment, i.e. the velocity with which the chemical process advances towards the equilibrium state, is given by the equation

\[
v = v' = k_0c_1c_2 \ldots - k'c'_1c'_2 \ldots
\]

This states the fundamental law of chemical kinetics.

The equilibrium equation is simply a special case of this more general one, and results when the total velocity is written zero, just as in analytical mechanics the equilibrium conditions follow at once by specialization of the general equations of motion.

No difficulty presents itself in the generalization of the previous equations for the reaction which proceeds after the scheme

\[
nA_1 + nA_2 + \ldots = nA'_1 + nA'_2 + \ldots
\]

where \( n_1, n_2, \ldots, n'_1, n'_2, \ldots \) denote the numbers of molecules of the separate substances which take part in the reaction, and are therefore whole, mostly small numbers (generally one or two, seldom three or more). Here as before, \( v \) and \( v' \) are to be regarded as proportional to the number of collisions at one point of all molecules necessary to the respective reaction, but now \( n_1 \) molecules of \( A_1, n_2 \) molecules of \( A_2, \ldots \), must collide for the reaction to advance from left to right in the sense of the equation; and similarly \( n'_1 \) molecules of \( A'_1, n'_2 \) molecules of \( A'_2, \ldots \), must collide for the reaction to proceed in the opposite direction. If we consider the path of a single, arbitrarily chosen molecule over a certain time, then the number of its collisions with other similar molecules will be proportional to the concentration \( C \) of that kind of molecule to which it belongs. The number of encounters between two molecules of the kind in question, during the same time, will be in general \( C \) times as many, i.e. the number of encounters of two of the same molecules is proportional to the square of the concentration \( C \); and generally, the number of encounters of \( n \) molecules of one kind must be regarded as proportional to the \( nth \) power of \( C \), i.e. \( C^n \).

The number of collisions of \( n_1 \) molecules of \( A_1, n_2 \) molecules of \( A_2, \ldots \) is accordingly proportional to \( C^nC'^n \ldots \), and the reaction-velocity corresponding to it is therefore

\[
v = kC^nC'^n \ldots
\]

and similarly the opposed reaction-velocity is

\[
v' = kC'^nC'^n \ldots
\]

the resultant reaction-velocity, being the difference of these two partial velocities, is therefore

\[
v = v' = kC^nC'^n \ldots - kC'^nC'^n \ldots
\]

This is the most general expression of the law of chemical mass-action, for the case of homogeneous systems.

Equating \( v \) to zero, we obtain the equation for the equilibrium state, viz.

\[
C^nC'^n \ldots / C'^nC'^n \ldots = k/k' = K;
\]

\( K \) is called the "equilibrium-constant."
CHEMICAL ACTION

These formulae hold for gases and for dilute solutions, but assume the system to be homogeneous, i.e. to be either a homogeneous gas-mixture or a homogeneous dilute solution. The case in which other states of matter share in the equilibrium permits of simple treatment when the substances in question may be regarded as pure, and consequently as possessing definite vapour-pressure or solubilities at a given temperature. In this case the molecular species in question, which is, at the same time, present in excess and is hence usually, called a *Bodenkörper*, must possess a constant concentration in the gas-space or solution. But since the left-hand side of the last equation contains only variable quantities, it is simplest and most convenient to absorb these constant concentrations into the equilibrium-constant; whence we have the rule: leave the molecular species present as *Bodenkörper* out of account, when determining the concentration-product. Guldberg and Waage expressed this in the form “the active mass of a solid substance is constant.” The same is true of liquids when these participate in the pure state in the equilibrium, and possess therefore a definite vapour-pressure or solubility. When, finally, we are not dealing with a dilute solution but with any kind of mixture whatever, it is simplest to apply the law of mass-action to the gaseous mixture in equilibrium with this. The composition of the liquid mixture is then determinable when the vapour-pressures of the separate components are known. This, however, is not often the case; but in principle this consideration is important, since it involves the possibility of extending the law of chemical mass-action from ideal gas-mixtures and dilute solutions, for which it primarily holds, to any other system whatever.

The more recent development of theoretical chemistry, as well as the detailed study of many chemical processes which have found technical application, leads more and more convincingly to the recognition that in the law of chemical mass-action we have a law of as fundamental significance as the law of constant and multiple proportions. It is therefore not without interest to briefly touch upon the development of the doctrine of chemical affinity.

Historical Development of the Law of Mass-action.—The theory developed by Torbern Olof Bergman in 1774 must be regarded as the earliest example of importance to account for the more complex action of chemical forces. The essential principle of this may be stated as follows:—The magnitude of chemical affinity may be expressed by a definite number; if the affinity of the substance A is greater for the substance B than for the substance C, then the latter (C) will be completely expelled by B from its compound with A, in the sense of the equation A+C>B=A+B+C.

This theory fails, however, to take account of the influence of the relative masses of the reacting substances, and had to be abandoned as soon as such an influence was noticed. An attempt to consider this factor was made by Claude Louis Berthelot (1801), who introduced the conception of chemical equilibrium. The views of this French chemist may be summed up in the following sentence:—Different substances have different affinities for each other, which only come into play on immediate contact. The condition of equilibrium depends not only upon the chemical affinity, but also essentially upon the relative masses of the reacting substances.

Essentially, Berthelot’s idea is to-day the guiding principle of the theory of affinity. This is especially true of our conceptions of many reactions which, in the sense of Bergman’s idea, proceed to completion, i.e. until the reacting substances are all used up; but only for this reason, viz. that one or more of the products of the reaction is removed from the reaction mixture (either by crystallization, evaporation or some other process), and hence the reverse reaction becomes impossible. Following Berthelot’s idea, two Norwegian investigators, C. M. Guldberg and Peter Waage, succeeded in formulating the influence of the reacting masses in a simple law—the law of chemical mass-action already defined. The results of their theoretical and experimental studies were published at Christiania in 1867 (*Brousses sur les affinités chimiques*); this work marks a new epoch in the history of chemistry. Even before this, formulae to describe the progress of certain chemical reactions, which must be regarded as applications of the law of mass-action, had been put forward by Ludwig Wilhelm (1850), and by A. G. Vernon-Harcourt and William Eison (1856), but the service of Guldberg and Waage in having grasped the law in its full significance and logically applied it in all directions, remains of course undiminished. Their treatise remained quite unknown; and so it happened that John Hewitt Jellett (1873), J. H. van’t Hoff (1877), and others independently developed the same law. The thermodynamic basis of the law of mass-action is primarily due to Horstmann, J. Willard Gibbs and van’t Hoff.

Applications.—Let us consider, as an example of the application of the law of mass-action, the case of the dissociation of water-vapour, which takes place at high temperatures in the sense of the equation $2H_2O = 2H_2 + O_2$. Representing the concentrations of the corresponding molecular species by [H₂], [O₂], the expression $[H_2]^2 [O_2]/[H_2O]^2$ must be constant at any given temperature. This shows that the dissociation is set back by increasing the pressure; for if the concentrations of all three kinds of molecules be increased by strong compression, say to a hundred times the former amounts, then the numerator is increased one thousand, the denominator only one hundred times. Hence if the original equilibrium-constant is to hold, the dissociation must go back, and what is more, by an exactly determinable amount. At 200°C. water-vapour is only dissociated to the extent of a few per cent; therefore, even when only a small excess of oxygen or hydrogen be present, the numerator in the foregoing expression is much increased, and it is obvious that in order to restore the equilibrium state, the concentration of the other component, hydrogen or oxygen as the case may be, must diminish. In the case of slightly dissociated substances, therefore, even a relatively small excess of one component is sufficient to set back the dissociation substantially.

Chemical Kinetics.—It has been already mentioned that the law of chemical mass-action not only defines the conditions for chemical equilibrium, but contains at the same time the principles of chemical kinetics. The previous considerations show indeed that the actual progress of the reaction is determined by the difference of the reaction-velocities in the one and the other (opposed) direction, i.e. by the negative logarithm of the corresponding reaction-constant. Since the reaction-velocity is given by the amount of chemical change in a small interval of time, the law of chemical mass-action supplies a differential equation, which, when integrated, provides formulae which, as numerous experiments have shown, very happily summarize the course of the reaction. For the simplest case, in which a single species of molecule undergoes almost complete decomposition, so that the reaction-velocity in the reverse direction may be neglected, we have the simple equation $dx/dt = k(a-x)$, and if $x = 0$ when $t = 0$ we have by integration $k = \frac{1}{a} \ln(a-x)$.

We will now apply these conclusions to the theory of the ignition of an explosive gas-mixture, and in particular to the combustion of “knallgas” (a mixture of hydrogen and oxygen) to water-vapour. At ordinary temperatures knallgas undergoes practically no change, and it might be supposed that the two gases, oxygen and hydrogen, have no affinity for each other. This conclusion, however, is shown to be incorrect by the observation that it is only necessary to add some suitable catalyst such as platinum-black in order to immediately start the reaction. We must therefore conclude that even at ordinary temperatures strong chemical affinity is exerted between oxygen and hydrogen, but that at low temperatures this affords great frictional resistances, or in other words that the reaction-velocity is very small. It is a matter of general experience that the resistances which the chemical forces have to overcome diminish with rising temperature, i.e. the reaction-velocity increases with temperature. Therefore, when we warm the knallgas, the number of collisions of oxygen and hydrogen molecules favourable to the formation of...
of water becomes greater and greater, until at about 500° the gradual formation of water is observed, while at still higher temperatures the reaction-velocity becomes enormous. We are now in a position to understand what is the result of a strong local heating of the knallgas, as, for example, by an electric spark. The strongly heated parts of the knallgas combine to form water-vapour with great velocity and the evolution of large amounts of heat, whereby the adjacent parts are brought to a high temperature and into a state of rapid reaction, i.e. we observe an ignition of the whole mixture. If we suppose the knallgas to be at a very high temperature, then its combustion will no longer continue owing to the dissociation of water-vapour, whilst at extremely high temperatures it would practically disappear. Hence it is clear that knallgas appears to be stable at low temperatures only because the reaction-velocity is very small, but that at very high temperatures it is really stable, since no chemical forces are then active, or, in other words, the chemical affinity is very small.

The determination of the question whether the failure of some reaction is due to an inappreciable reaction-velocity or to absence of chemical affinity, is of fundamental importance, and only in the first case can reaction be hastened by catalysts. Many chemical compounds behave like knallgas. Acetylene is stable at ordinary temperatures, inasmuch as it only decomposes slowly; but at the same time it is explosive, for the decomposition when once started is rapidly propagated, on account of the heat evolved by the splitting up of the gas into carbon and hydrogen. At very high temperatures, however, acetylene acquires real stability, since carbon and hydrogen then react to form acetylene.

Many researches have shown that the combustion of an inflammable gas-mixture which is started at a point, e.g. by an electric spark, may be propagated in two essentially different ways. The characteristic of the slower combustion consists in this, viz. that the high temperature of the previously ignited layer spreads by conduction, thereby bringing the adjacent layers to the ignition-temperature; the velocity of the propagation is therefore conditioned in the first place by the magnitude of the conductivity for heat, and more particularly, in the second place, by the velocity with which a moderately heated layer begins to react chemically, and so to rise gradually in temperature, i.e. essentially by the change of reaction-velocity with temperature. A second entirely independent mode of propagation of the combustion lies at the basis of the phenomenon that an explosive gas-mixture can be ignited by strong compression or—more correctly—by the rise of temperature thereby produced. The increase of the concentrations of the reacting substances consequent upon this increase of pressure raises the reaction-velocity in accordance with the law of chemical mass-action, and so enormously favours the rapid evolution of the heat of combustion.

It is therefore clear that such a powerful compression-wave can not only initiate the combustion, but also propagate it with extremely high velocity. Indeed a compression-wave of this kind passes through the gas-mixture, heated by the combustion to a very high temperature. It must, however, be propagated considerably faster than an ordinary combustion-wave, for the reason that the ignited (unburnt) layer is the production of a very high pressure, which must in accordance with the principles of wave-motion increase the velocity of propagation. The absolute velocity of the explosion-wave would seem, in the light of these considerations, to be susceptible of accurate calculation. It is at least clear that it must be considerably higher than the velocity of sound in the mass of gas strongly heated by the explosion, and this is confirmed by actual measurements (see below) which show that the velocity of the explosion-wave is from one and a half times to double that of sound-waves at the combustion temperature.

We are now in a position to form the following picture of the processes which follow upon the ignition of a combustible gas-mixture contained in a long tube. First we have the condition of slow combustion; the heat is conveyed by conduction to the adjacent layers, and there follows a velocity of propagation of a few metres per second. But since the combustion is accompanied by a high increase of pressure, the adjacent, still unburnt layers are simultaneously compressed, whereby the reaction-velocity increases, and the ignition proceeds faster. This involves still greater compression of the next layers, and so forth the mixture be capable of sufficiently rapid combustion, the velocity of propagation of the ignition must continually increase. As soon as the compression in the still unburnt layers becomes so great that spontaneous ignition results, the now much more pronounced compression-waves excited with simultaneous combustion must be propagated with very great velocity, i.e. we have spontaneous development of an "explosion-wave." M. P. E. Berthelot, who discovered the presence of such explosion-waves, proved their velocity of propagation to be independent of the pressure, the cross-section of the tubes in which the explosive gas-mixture is contained, as well as of the material of which these are made, and concluded that this velocity is a constant, characteristic of the particular mixture. The determination of this velocity is naturally of the highest interest.

In the following table Berthelot's results are given along with the later (1892) concordant ones of H. B. Dixon, the velocities of propagation of explosions being given in metres per second.

The maximum pressure of the explosion-wave possesses very high values; it appears that a compression of from 1 to 30-40 atmospheres is necessary to produce spontaneous ignition of mixtures of oxygen and hydrogen. But since the heat evolved in the path of the explosion causes a rise of temperature of 2000°-3000°, i.e. a rise of absolute temperature about four times that directly following upon the initial compression, we are here concerned with pressures amounting to considerably more than 100 atmospheres. Both the magnitude of this pressure and the circumstance that it so suddenly arises are peculiar to the very powerful forces which distinguish the explosion-wave from the slow combustion-wave.

**Nascent State.**—The great reactive power of freshly formed or nascent substances (status nascendi) may be very simply referred to the principles of mass-action. As is well known, this phenomenon is specially striking in the case of hydrogen, which may therefore be taken as a typical example. The law of mass-action affirms the action of a substance to be the greater the higher its concentration, or, for a gas, the higher its partial pressure. Now experience teaches that those metals which liberate hydrogen from acids are able to supply the latter under extremely high pressure, and we may therefore assume that the hydrogen which results, for example, from the action of zinc upon sulphuric acid is initially under very high pressures which are then afterwards relieved. Hence the hydrogen during liberation exhibits much more active powers of reduction than the ordinary gas.

A deeper insight into the relations prevailing here is offered from the atomistic point of view. From this we are bound to conclude that the hydrogen is in the first instance evolved in the form of free atoms, and since the velocity of the reaction H + H = H₂ at ordinary temperatures, though doubtless very great, is not practically instantaneous, the freshly generated hydrogen will contain a remnant of free atoms, which are able to react both more actively and more rapidly. Similar considerations are of course applicable to other cases.

**Ion-reactions.**—The application of the law of chemical mass...
CHEMICAL ACTION

action is much simplified in the case in which the reaction-velocity is enormously great, when practically an instantaneous adjustment of the equilibrium results. Only in this case can the state of the system, which obtains after mixing the different components, be determined merely from knowledge of the equilibrium-constant. When it has been thoroughly studied on account of its fundamental importance for inorganic qualitative and quantitative analysis, the degrees of dissociation of the various electrolytes (acids, bases and salts) are for the most part easily determined by the aid of the freezing-point apparatus, or of measurements of the electric conductivity; and from these data the equilibrium-constant \( K \) may be calculated. Moreover, it can be shown that the state of the system can be determined when the equilibrium constants of all the electrolytes which are present in the common solution are known. If this be coupled with the law that the solubility of solid substances, as with vapour-pressures, is independent of the presence of other electrolytes, it is sufficient to know the solubilities of the electrolytes in question, in order to be able to determine which substances must participate in the equilibrium in the solid state, i.e. we arrive at the theory of the formation and solution of precipitates.

As an illustration of the application of these principles, we shall deal with a problem of the doctrine of affinity, namely, that of the relative strengths of acids and bases. It was quite an early and often repeated observation that the various acids and bases take part with very varying intensity or avidity in those reactions in which their acid or basic nature comes into play. No success attended the early attempts at giving numerical expression to the strengths of acids and bases, i.e. of finding a numerical coefficient for each acid and base, which should be the quantitative expression of the degree of its participation in those specific reactions characteristic of acids and bases respectively. Julius Thomsen and W. Ostwald attacked the problem in a far-seeing and comprehensive manner, and arrived at indisputable proof that the property of acids and bases of exerting their effects according to definite numerical coefficients finds expression not only in salt-formation but also in a large number of other, and indeed very miscellaneous, reactions.

When Ostwald compared the order of the strengths of acids deduced from their competition for the same base, as determined by Thomsen's thermo-chemical or his own volumetric method, with that order in which the acids arrange themselves according to their capacity to bring calcium oxalate into solution, or to convert acetamide into ammonium acetate, or to split up methyl acetate into methyl alcohol and acetic acid catalytically, or to invert cane-sugar, or to accelerate the mutual action of hydrobromic acid on boric acid, he found that in all these well-investigated and very miscellaneous cases the same succession of acids in the order of their strengths is obtained, whichever one of the above chemical processes be chosen as measure of these strengths.

It is evident, therefore, that the chemical character of acids is not to be changed in aqueous solution, consequently the above order of acids refers only to the power to react under these circumstances. The order of acids proved to be fairly independent of temperature. While therefore the above investigations afforded a definite qualitative solution of the order of acids according to strengths, the determination of the quantitative relations offered great difficulties, and the numerical coefficients, determined from the separate reactions, often displayed great variations, though occasionally also surprising agreement. Especially great were the variations of the coefficients with the concentration, and in those cases in which the concentration of the acid changed considerably during the reaction, the calculation was naturally quite uncertain. Similar relations were found in the investigation of bases, the scope of which, however, was much more limited.

These apparently rather complicated relations were now cleared up at one stroke, by the application of the law of chemical mass-action on the lines indicated by S. Arrhenius in 1887, when he put forward the theory of electrolytic dissociation to explain that peculiar behaviour of substances in aqueous solution first recognized by van't Hoff in 1885. The formulae which must be made use of here in the calculation of the equilibrium-constants follow naturally by simple application of the law of mass-action to the corresponding ion-concentrations.

The peculiarities which the behaviour of acids and bases presents, and, according to the theory of Arrhenius, must present—peculiarities which found expression in the very early distinction between neutral solutions on the one hand, and acid or basic ones on the other, as well as in the belief in a polar antithesis between the two last—must now, in the light of the theory of electrolytic dissociation, be conceived as follows:—

The reactions characteristic of acids in aqueous solution, which are common to and can only be brought about by acids, find their explanation in the fact that this class of bodies gives rise on dissociation to a common molecular species, namely, the positively charged hydrogen-ion \( \text{H}^+ \). The specific chemical actions peculiar to acids are therefore to be attributed to the hydrogen-ion just as the actions common to all chlorides are to be regarded as those of the free chlorine-ions. In like manner, the reactions characteristic of bases in solution are to be attributed to the negatively charged hydroxyl-ions \( \text{OH}^- \), which result from the dissociation of this class of bodies.

A solution has an acid reaction when it contains an excess of hydrogen-ions, and a basic reaction when it contains an excess of hydroxyl-ions. If an acid and an alkaline solution be brought together mutual neutralization must result, since the positive \( \text{H}^- \) and the negative \( \text{OH}^- \) ions cannot exist together in view of the extremely weak conductivity of pure water and its consequent slight electrolytic dissociation, and therefore they must at once combine to form electrically neutral molecules, in the sense of the equation

\[
\text{H}^+ + \text{OH}^- \rightarrow \text{H}_2\text{O}
\]

In this lies the simple explanation of the "polar" difference between acid and basic solutions. This rests essentially upon the fact that the ion peculiar to acids and the ion peculiar to bases form the two constituents of water, i.e. of that solvent in which we usually study the course of the reaction. The idea of the "strength" of an acid or base at once comes into its own. If we compare equivalent solutions of various acids, the intensity of those actions characteristic of them will be the greater the more free hydrogen-ions they contain; this is an immediate consequence of the law of chemical mass-action. The degree of electrolytic dissociation determines, therefore, the strength of acids, and a similar consideration leads to the same result for bases.

Now the degree of electrolytic dissociation changes with concentration in a regular manner, which is given by the law of mass-action. For if \( C \) denote the concentration of the electrolyte and \( a \) its degree of dissociation, the above law states that

\[
\text{Ca}^a/\text{C}(1-a) = \text{Ca}^a/(1-a) = K.
\]

At very great dilutions the dissociation is complete, and equivalent solutions of the most various acids therefore contain the same number of hydrogen-ions, or, in other words, are equally strong; and the same is true of the hydroxyl-ions of bases. The dissociation also decreases with increasing concentration, but at different rates for different substances, and the relative "strengths" of acids and bases must hence change with concentration, as was indeed found experimentally. The dissociation-constant \( K \) is the measure of the variation of the degree of dissociation with concentration, and must therefore be regarded as the measure of the strengths of acids and bases. So that in this special case we are again brought to the result which was stated in general terms above, viz. that the dissociation-coefficient forms the measure of the reactivity of a dissolved electrolyte. Ostwald's series of acids, based upon the investigation of the most various reactions, should therefore correspond with the order of their dissociation-constants, and further with the...
order of their freezing-point depressions in equivalent solutions, since the depression of the freezing-point increases with the degree of electrolytic dissociation. Experience confirms this conclusion completely. The degree of dissociation of an acid, at a given concentration, for which its molecular conductivity is \( \Lambda \), is shown by the theory of electrolytic dissociation to be
\[
a = \frac{\Lambda}{\Lambda_{\infty}}; \quad \Lambda_{\infty}
\]
the molecular conductivity at very great dilution in accordance with the law of Kohlrausch, is \( u + v \), where \( u \) and \( v \) are the ionic-mobilities (see Conduction, Electric). Since \( u \), the ionic-mobility of the hydrogen ion, is generally more than ten times as great as \( v \), the ionic-mobility of the negative acid-radical, \( \Lambda_{\infty} \) has approximately the same value (generally within less than 10%) for the different acids, and the molecular-conductivity of the acids in equivalent concentration is at least approximately proportional to the degree of electrolytic dissociation, i.e. to the strength.

In general, therefore, the order of conductivities is identical with that in which the acids exert their specific powers. This remarkable parallelism, first perceived by Arrhenius and Ostwald in 1885, was the happy development which led to the discovery of electrolytic dissociation (see Conduction, Electric; and Solution).

**Catalysis.**—We have already mentioned the fact, early known to chemists, that many reactions proceed with a marked increase of velocity in presence of many foreign substances. With Berzelius we call this phenomenon "catalysis," by which we understand that general acceleration of reactions which also progress when left to themselves, in the presence of certain bodies which do not change in amount (or only slightly) during the course of the reaction. Acids and bases appear to act catalytically upon all reactions involving consumption or liberation of water, and indeed that action is proportional to the concentration of the hydrogen or hydroxyl-ions. Further, the decomposition of hydrogen peroxide is "catalysed" by iodine-ions, the condensation of two molecules of benzaldehyde to benzoin by cyanogen-ions. One of the earliest known and technically most important instances of catalysis is that of the oxidation of sulphur dioxide to sulphuric acid by oxygen in the presence of oxides of nitrogen. Other well-known and remarkable examples are the catalysis of the combustion of hydrogen and of sulphur dioxide in oxygen by finely-divided platinum. We may also mention the interesting work of Dixon and Baker, which led to the discovery that a large number of gas-reactions, e.g. the combustion of carbon monoxide, the dissociation of sal-ammoniac vapour, and the action of sulphuretted hydrogen upon the salts of heavy metals, cease when water-vapour is absent, or at least proceed with greatly diminished velocity. "Negative catalysis," i.e. the retardation of a reaction by addition of some substance, which is occasionally observed, appears to depend upon the destruction of a "positive catalyse" by the body added.

A catalyse can have no influence, however, upon the affinity of a process, since that would be contrary to the second law of thermodynamics, according to which affinity of an isothermal process, which is measured by the maximum work, only depends upon the initial and final states. The effect of a catalyse is therefore limited to the resistances opposing the progress of a reaction, and does not influence its driving-force or affinity. Since the catalyse takes no part in the reaction its presence has no effect on the equilibrium-constant. This, in accordance with the law of mass-action, is the ratio of the separate reaction-velocities in the two contrary directions. A catalyse must therefore always accelerate the reverse-reaction. If the velocity of formation of a body be increased by addition of some substance then its velocity of decomposition must likewise increase. We have an example of this in the well-known fact that the formation, and no less the saponification, of esters, proceeds with increased velocity in the presence of acids, while the observation that in absence of water-vapour neither gaseous ammonium chloride dissociates nor dry ammonia combines with hydrogen chloride becomes clear on the same grounds.

A general theory of catalytic phenomena does not at present exist. The formation of intermediate products by the action of the reacting substance upon the catalyse has often been thought to be the cause of these. These intervening products, whose existence in many cases has been proved, then split up into the catalyse and the reaction-product. Thus chemists have sought to ascribe the influence of oxides of nitrogen on the formation of sulphuric acid to the initial formation of nitrosyl-sulphuric acid, \( \text{SO}_2\text{OH}(\text{NO}_3) \), from the mixture of sulphur dioxide, oxides of nitrogen and air, which then reacted with water to form sulphuric and nitrous acids. When the velocity of such intermediate reactions is greater than that of the total change, such an explanation may suffice, but a more certain proof of this theory of catalysis has only been reached in a few cases, though in many others it appears very plausible. Hence it is hardly possible to interpret all catalytic processes on these lines.

In regard to catalysis in heterogeneous systems, especially the hastening of gas-reactions by platinum, it is very probable that it is closely connected with the solution or absorption of the gases on the part of the metal. From the experiments of G. Bredig it seems that colloidal solutions of a metal act like the metal itself. The action of a colloidal-platinum solution on the decomposition of hydrogen peroxide is still sensible even at a dilution of \( 1/50,000 \) grm.-mol. per litre; indeed the activity of this colloidal-platinum solution calls to mind in many ways that of organic fermentes, hence Bredig has called it an "inorganic ferment." This analogy is especially striking in the change of their activity with time and temperature, and in the possibility, by means of bodies like sulphuretted hydrogen, hydrocyanic acid, &c., which act as strong poisons upon the latter, of "poisoning" the former also, i.e. of rendering it inactive. In the case of the catalytic action of water-vapour upon many processes of combustion already mentioned, a part of the effect is probably due to the circumstance, disclosed by numerous experiments, that the union of hydrogen and oxygen proceeds, between certain temperature limits at least, after the equation \( \text{H}_2 + \text{O}_2 = \text{H}_2\text{O} \), that is, with the preliminary formation of hydrogen peroxide, which then breaks down into water and oxygen, and further, above all, to the fact that this substance results from oxygen and water at high temperatures with great velocity, though indeed only in small quantities.

The view now suggests itself, that, for example, in the combustion of carbon monoxide at moderately high temperatures, the reaction
\[
(\text{I}) \quad 2\text{CO} + \text{O}_2 = 2\text{CO}_2
\]
advances with imperceptible speed, but that on the contrary the two stages
\[
(\text{II}) \quad 2\text{H}_2 + \text{O}_2 = 2\text{H}_2\text{O} \quad \text{and} \quad (\text{III}) \quad 2\text{CO} + 2\text{H}_2\text{O} = 2\text{CO}_2 + 2\text{H}_2\text{O},
\]
which together result in (I), proceed rapidly even at moderate temperatures.

**Temperature and Reaction-Velocity.**—There are few natural constants which undergo so marked a change with temperature as those of the velocities of chemical changes. As a rule a rise of temperature of 10° causes a twofold or threefold rise of reaction-velocity.

If the reaction-coefficient \( k \), in the sense of the equation derived above, viz. \( k = \text{e}^{-\frac{E}{RT}} \), be determined for the inversion of cane-sugar by an acid of given concentration, the following values are obtained:

<table>
<thead>
<tr>
<th>Temperature</th>
<th>25°</th>
<th>40°</th>
<th>45°</th>
<th>50°</th>
<th>55°</th>
</tr>
</thead>
<tbody>
<tr>
<td>( k )</td>
<td>97</td>
<td>73</td>
<td>139</td>
<td>268</td>
<td>491</td>
</tr>
</tbody>
</table>

here a rise of temperature of only 30° suffices to raise the speed of inversion fifty times.

We possess no adequate explanation of this remarkable temperature influence; but some account of it is given by the molecular theory, according to which the energy of that motion of substances in homogeneous gaseous or liquid systems which constitutes heat increases with the temperature, and hence also the frequency of collision of the reacting substances. When we reflect that the velocity of motion of the molecules of gases, and in all probability those of liquids also, are proportional to the square root of the absolute temperature, and therefore rise by
only \( \frac{1}{2} \) % per degree at room-temperature, and that we must assume the number of collisions proportional to the velocity of the molecules, we cannot regard the actually observed increase of reaction-velocity, which often amounts to 10 or even \( \frac{1}{2} \) % per degree, as exclusively due to the increase of the molecule velocities.

It is more probable that the increase of the kinetic energy of the atomic motions within the molecule itself is of significance here, as the rise of the specific heat of gases with temperature seems to show. The change of the reaction-coefficient \( k \) with temperature may be represented by the empirical equation

\[
\log k = -\frac{\Delta T}{T} + B + CT,
\]

where \( A, B, C \) are positive constants. For low temperatures the influence of the last term is as a rule negligible, whilst for high temperatures the first term on the right side plays a vanishingly small part.

**Definition of Chemical Affinity.**—We have still to discuss the question of what is to be regarded as the measure of chemical affinity. Since we are not in a position to measure directly the intensity of chemical forces, the idea suggests itself to determine the strength of chemical affinity from the amount of the work which the corresponding reaction is able to do. To a certain extent the evolution of heat accompanying the reaction is a measure of this work, and attempts have been made to measure chemical affinities thermo-chemically, though it may be easily shown that this definition was not well chosen. For when, as is clearly most convenient, affinity is so defined that it determines under all circumstances the direction of chemical change, the above definition fails. So far chemical processes often take place with absorption of heat, that is, contrary to affinities so defined. But even in those cases in which the course of the reaction at first proceeds in the sense of the evolution of heat, it is often observed that the reaction advances not to completion but to a certain equilibrium, or, in other words, stops before the evolution of heat is complete.

A definition free from this objection is supplied by the second law of thermodynamics, in accordance with which all processes must take place in so far as they are able to do external work. When therefore we identify chemical affinity with the maximum work which can be gained from the process in question, we reach such a definition that the direction of the process is under all conditions determined by the affinity. Further, this definition has proved serviceable in so far as the maximum work in many cases may be experimentally measured, and moreover it stands in a simple relation to the equilibrium constant \( K \). Thermodynamics teaches that the maximum work \( A \) may be expressed as \( A = RT \log K \), where \( K \) denotes the gas-constant, \( T \) the absolute temperature.

In this it is further assumed that both the molecular species produced as well as those that disappear are present in unit concentration. The simplest experimental method of directly determining chemical affinity consists in the measurement of electromotive force. The latter at once gives us the work which can be gained when the corresponding galvanic element supplies the electricity, and, since the chemical exchange of one gram-equivalent from Faraday’s law requires 96,540 coulombs, we obtain from the product of this number and the electromotive force the work per gram-equivalent in watt-seconds, and this quantity when multiplied by \( 0.2587 \) is obtained in terms of the usual unit, the gram-calorie.

Experience teaches that, especially when we have to deal with strong affinities, the affinity so determined is for the most part almost the same as the heat-evolution, whilst in the case in which only solid or liquid substances in the pure state take part in the reaction at low temperatures, heat-evolution and affinity appear to possess a practically identical value.

Hence it seems possible to calculate equilibria for low temperatures from heats of reaction, by the aid of the two equations

\[
A = Q, \quad A = RT \log K;
\]

and since the change of \( A \) with temperature, as required by the principles of thermodynamics, follows from the specific heats of the reacting substances, it seems further possible to calculate chemical equilibria from heats of reaction and specific heats. The circumstance that chemical affinity and heat-evolution so nearly coincide at low temperatures may be derived from the hypothesis that chemical processes are the result of forces of attraction between the atoms of the different elements. If we may disregard the kinetic energy of the atoms, and this is legitimate for low temperatures, it follows that both heat-evolution and chemical affinity are nearly equal to the decrease of the potential energy of the above-mentioned forces, and it is at once clear that the evolution of heat during a reaction between only pure solid or pure liquid substances possesses special importance.

More complicated is the case in which gases or dissolved substances take part. This is simplified if we first consider the mixing of two mutually chemically indifferent gases. Thermodynamics teaches that external work may be gained by the mere mixing of two such gases (see Diffusion), and these amounts of work, which assume very considerable proportions at high temperatures, naturally affect the value of the maximum work and so also of the affinity, in that they always come into play when gases or solutions react. While therefore we regard as chemical affinity in the strictest sense the decrease of potential energy of the forces acting between the atoms, it is clear that the quantities here involved exhibit the simplest relations under the experimental conditions just given, for when only substances in a pure state take part in a reaction, all mixing of different kinds of molecules is excluded; moreover, the circumstance that the respective substances are considered at very low temperatures reduces the quantities of energy absorbed as kinetic energy by their molecules to the smallest possible amount.

Chemical affinity is often defined by the chemical affinity of the reaction; we are in a position to decide in which direction the process must advance, but, unless we know the reaction-velocity also, we can in many cases say nothing as to whether or not the reaction in question will progress with a practically inappreciable velocity so that apparent chemical indifference is the result. This question may be stated in the light of the law of mass-action briefly as follows:—From a knowledge of the chemical affinity we can calculate the equilibrium, i.e. the numerical value of the constant \( K = \frac{b}{a} \); but to be completely informed of the process we must know not only the ratio of the two velocity-constants \( a \) and \( b \), but also the separate absolute values of the same.

In many respects the following view is more comprehensive, though naturally in harmony with the one just expressed. Since the chemical equilibrium is periodically attained, it follows that, as in the case of the motion of a body or of the diffusion of a dissolved substance, it must be opposed by very great friction. In all these cases the velocity of the process at every instant is directly proportional to the driving-force and inversely proportional to the frictional resistance. We hence arrive at the result that an equation of the form

\[
\text{reaction-velocity} = \frac{\text{chemical force}}{\text{chemical resistance}}
\]

must also hold for chemical change; here we have an analogy with Ohm’s law. The “chemical force” at every instant may be calculated from the maximum work (affinity); as yet little is known about “chemical resistance,” but it is not improbable that it may be directly measured or theoretically deduced. The problem of the calculation of chemical reaction-velocity in absolute measure would then be solved; so far we possess only a few general facts concerning the magnitude of chemical resistance. It is immeasurably small at ordinary temperatures for ion-reactions, and, on the other hand, fairly large for nearly all reactions in which carbon-bonds must be loosened (so-called “inertia of the carbon-bond”) and possesses very high values for most gas-reactions also. With rising temperature it always strongly diminishes; on the other hand, at very low temperatures its value is always enormous, and at the absolute zero of temperature may be infinitely great. Therefore at that temperature all reactions cease, since the denominator in the above expression assumes enormous values.

It is a very remarkable phenomenon that the chemical resistance is often small in the case of precisely those reactions in which the affinity is also small; to this circumstance is to be traced the fact that in many chemical changes the most stable condition is not at once reached, but is preceded by the formation
of more or less unstable intermediate products. Thus the unstable ozone is very often first formed on the evolution of oxygen, whilst in the reaction between oxygen and hydrogen water is often not at once formed, but first the unstable hydrogen peroxide as an intermediate product.

Let us now consider the chemical process in the light of the equation

\[ \text{reaction} = \text{velocity} = \text{chemical force}/\text{chemical resistance}. \]

Thermodynamics shows that at very low temperatures, i.e., in the immediate vicinity of the absolute zero, there is no equilibrium, but every chemical process advances to completion in the one or the other direction. The chemical forces therefore act in the one direction towards complete consumption of the reacting substance. But since the chemical resistance is now immensely great, they can produce practically no appreciable result.

At higher temperatures the reaction always proceeds, at least in homogeneous systems, to a certain equilibrium, and as the chemical resistance now has finite values this equilibrium will always finally be reached after a longer or shorter time. Finally, at very high temperatures the chemical resistance is in every case very small, and the equilibrium is almost instantaneously reached; at the same time, the affinity of the reaction, as in the case of the mutual affinity between oxygen and hydrogen, may very strongly diminish, and we have then chemical indifference again, not because, as at low temperatures, the denominator of the previous expression becomes very great, but because the numerator now assumes vanishingly small values. (W. N.)

CHEMISTRY (formerly "chemistry"; Gr. χημεία; for derivation see ALCHEMY), the natural science which has for its province the study of the composition of substances. In common with physics it includes the determination of properties or characters which serve to distinguish one substance from another, but while the physicist is concerned with properties possessed by all substances and with substances in which the molecules remain intact, the chemist is restricted to those processes in which the molecules undergo some change. For example, the physicist determines the density, elasticity, hardness, electrical and thermal conductivity, thermal expansion, &c.; the chemist, on the other hand, investigates changes in composition, such as may be effected by an electric current, or by heat, or when two or more substances are mixed. A further differentiation of the provinces of chemistry and physics is shown by the classifications of matter. To the physicist matter is presented in three leading forms—solids, liquids and gases; and although further subdivisions have been rendered necessary with the growth of knowledge the same principle is retained, namely, a classification based on properties having no relation to composition. The fundamental chemical classification of matter, on the other hand, recognizes two groups of substances, namely, elements, which are substances not admitting of analysis into other substances, and compounds, which do admit of analysis into simpler substances and are of synthesis from simple substances. Chemistry, however,15 is based not only on common ground in a well-defined branch of science, named physical chemistry, which is primarily concerned with the correlation of physical properties and chemical composition, and, more generally, with the elucidation of natural phenomena on the molecular theory.

It may be convenient here to state how the whole subject of chemistry is treated in this edition of the Encyclopædia Britannica. The present article includes the following sections:

I. History.—This section is confined to the general trend of the science from its infancy to the foundations of the modern theories. The history of the alchemical period is treated in more detail in the article ALCHEMY, and of the artificial chemistry in the article MEDICINE. The evolution of the notion of elements is treated under ELEMENT; the molecular hypothesis of matter under MOLECULE; and the development of, and deduction from, the atomic theory of Dalton by receiving detailed analysis in the article ATOM.

II. Principles.—This section treats of such subjects as nomenclature, formulae, chemical equations, chemical change and similar subjects. It is intended to provide an introduction, necessarily brief, to the terminology and machinery of the chemical processes and composition.

III. Inorganic Chemistry.—Here is treated the history of descriptive inorganic chemistry; reference should be made to the articles on the separate elements for an account of their preparation, properties, &c.

IV. Organic Chemistry.—This section includes a brief history of the subject, and proceeds to treat of the principles underlying the structure and interrelations of organic compounds.

V. Analytical Chemistry.—This section treats of the qualitative detection of metals, and the commoner methods employed in quantitative analysis. The analysis of organic compounds is also noticed.

VI. Physical Chemistry.—This section is restricted to an account of the processes existing between the physical properties and chemical composition. Other branches of this subject are treated in the articles CHEMICAL ACTION; ENERGETICS; SOLUTION; ALLOYS; THERMOCHEMISTRY.

I. History

Although chemical actions must have been observed by man in the most remote times, and also utilized in such processes as the extraction of metals from their ores and in the arts of tanning and dyeing, there is no evidence to show that, beyond an unordered accumulation of facts, the early developments of these industries were attended by any real knowledge of the nature of the processes involved. All observations were the result of accident or chance, or possibly in some cases of experimental trial, but there is no record of a theory or even a general classification of the phenomena involved, although there is no doubt that the ancients had a fair knowledge of the properties and uses of the commoner substances. The origin of chemistry is intimately bound up with the arts which we have indicated; in this respect it is essentially an experimental science. A unifying principle of chemical and physical changes was provided by metaphysical conceptions of the structure of matter. We find the notion of "elements," or primary qualities, which confer upon all species of matter their distinctive qualities by appropriation and combination, and the doctrine that this essence is composed of minute discrete particles, prevailing in the Greek schools. These "elements," however, had not the significance of the elements of to-day; they connoted physical appearances or qualities rather than chemical relations; and the atomic theory of the ancients is a speculation based upon metaphysical considerations, having, in its origin, nothing in common with the modern molecular theory, which was based upon experimentally observed properties of gases (see ELEMENT; MOLECULE).

Although such hypotheses could contribute nothing directly to the development of a science which laid especial claim to experimental investigations, yet indirectly they stimulated inquiry into the nature of the "essence" with which the four "elements" were associated. This prima essentia had been speculated upon by the Greeks, some regarding it as material or aethereal, and others as material; and a school of philosophers termed alchemists arose who attempted the isolation of this essence. The existence of a fundamental principle, unalterable and indestructible, prevailing alike through physical and chemical changes, was generally accepted. Any change which a substance may chance to undergo was simply due to the discarding or taking up of some proportion of the primary "elements" or qualities: of these coverings "water," "air," "earth" and "fire" were regarded as clinging most tenaciously to the essence, while "cold," "heat," "moistness" and "dryness" were more easily cast aside or assumed. Several origins have been suggested for the word alchemy, and some authors have held the etymology as of no decisive value; there seems to have been some doubt as to the exact nature and import of the alchemical doctrines. According to M. P. E. Berthelot, "Alchemy rested partly on the industrial processes of the ancient Egyptians, partly on the speculative theories of the Greek philosophers, and partly on the mystical reverence of certain ancient oriental traditions." The word "alchemy" subsequently resolved itself into the desire to effect the transmutation of metals, more especially the base metals, into silver and gold. It seems that this secondary principle became the dominant idea in alchemy, and in this sense the word is used in Byzantine literature of the 4th century; Suidas, writing in ALCHEMY.
CHEMISTRY

The second half of the 17th century witnessed remarkable transitions and developments in all branches of natural science, and the facts accumulated by preceding generations during their generally unordered researches were replaced by a co-ordination of experiment and deduction. From the mazy and incoherent alchemic and iatrochemical doctrines, the former based on false conceptions of matter, the latter on erroneous views of life processes and physiology, a new science arose—the study of the composition of substances. The formulation of this definition of chemistry was due to Robert Boyle. In his *Sceptical Chemist* (1662) he freely criticized the prevailing scientific views and methods, with the object of showing that true knowledge could only be gained by the logical application of the principles of experiment and deduction. Boyle's masterly exposition of this method is his most important contribution to scientific progress. At the same time he clarified the conception of elements and compounds, rejecting the older notions, the four elements of the "vulgar Peripatetics" and the three principles of the "vulgar Stagyristis," and defining an element as a substance incapable of decomposition, and a compound as composed of two or more elements. He explained chemical combination, the mutual affinity of substances, and showed that by the coalescence of corpuscles of different substances distinctly new corpuscles of a compound were formed, and that each corpuscle had a certain affinity for other corpuscles.

Although Boyle practised the methods which he expounded, he was unable to gain general acceptance of his doctrine of elements; and, strangely enough, the theory which next dominated chemical thought was an alchemical invention, and lacked the lucidity and perspicuity of Boyle's views. This theory, named the phlogistic theory, was primarily based upon certain experiments on combustion and calcination, and in effect reduced the number of the alchemical principles, while setting up a new one, a principle of combustibility, named phlogiston (from φλόγας, burnt). Much discussion had centred about fire or the "igneous principle." On the one hand, it had been held that when a substance was burnt or calcined, it combined with an "air"; on the other hand, the operation was supposed to be attended by the destruction or loss of the igneous principle. Georg Ernst Stahl, following in some measure the views held by Johann Joachim Becher, as far as he could, that all combustible matter (of which the notion itself is of older date than Becher's terra pinguis), regarded all substances as capable of resolution into two components, the inflammable principle phlogiston, and another element—"water," "acid" or "earth." The violence or completeness of combustion was proportional to the amount of phlogiston present. Combustion meant the liberation of phlogiston. Metals on calcination gave calces from which the metals could be recovered by adding phlogiston, and experiment showed that this could generally be effected by the action of coal or carbon, which was therefore regarded as practically pure phlogiston; the other constituent being regarded as an acid. At the hands of Stahl and his school, the phlogistic theory, by exhibiting a fundamental similarity between all processes of combustion and by its remarkable flexibility, came to be a general theory of chemical action. The objections of the antiphlogistonists, such as the fact that calces weigh more than the original metals instead of less as the theory suggests, were answered by postulating that phlogiston was a principle of levity, or even completely ignored as an accident, the change of quality being regarded as the only matter of importance. It is remarkable that this theory should have gained the esteem of the notable chemists who flourished in the 18th century. Henry Cavendish, a careful and accurate experimenter, was a phlogistonist, as were J. Black, K. W. Scheele, A. S. Marggraf, J. Priestley and many others who might be mentioned.

---

1 The more notable chemists of this period were Turquet de Mayerne (1573–1656), a physician of Paris, who rejected the Galenic doctrines and accepted the exaggerations of Paracelsus; Andreas Libavius (d. 1616), chiefly famous for his *Opera Omnia Medico-chymica* (1595); Jean Baptistie van Helmont (1577–1644), celebrated for his researches on gases; F. de la Boë Sylvius (1614–1672), who regarded medicine as applied chemistry; and Otto Tachenius, who elucidated the nature of salts.
Descriptive chemistry was now assuming considerable proportions; the experimental inquiries suggested by Boyle were being assiduously developed; and a wealth of observations was being accumulated, for the explanation of which the resources of the dominant theory were sorely taxed.

To quote Antoine Laurent Lavoisier, "...chemists have turned phlogiston into a vague principle, ... which consequently adapts itself to all the explanations for which it may be required. Sometimes this principle has weight, and sometimes it has not; sometimes it is free fire and sometimes it is fire combined with the earthy element; sometimes it passes through the pores of vessels, sometimes they are impervious to it; it explains both causticity and non-causticity, transparency and opacity, colours and their absence; it is a veritable Proteus changing in form at each instant." Lavoisier may be justly regarded as the founder of modern or quantitative chemistry. First and foremost, he demanded that the balance must be used in all investigations into chemical changes. He established as fundamental that combustion and calcination were attended by an increase of weight, and concluded, as did Jean Rey and John Mayow in the 17th century, that the increase was due to the combination of the metal with the air. The problem could obviously be completely solved only when the composition of the air, which was generally regarded as a mixture of calx and aird, was made known. At all times the air had received attention, especially since van Helmont made his far-reaching investigations on gases. Mayow had suggested the existence of two components, a spiritus nitro-aerus which supported combustion, and a spiritus nitri acidi which extinguished fire; J. Priestley and K. W. Scheele, although they isolated oxygen, were fogged by the phlogistic tenets; and H. Cavendish, who had isolated the nitrogen of the atmosphere, had failed to decide conclusively what had really happened to the air which disappeared during combustion.

Lavoisier adequately recognized and acknowledged how much he owed to the researches of others; to himself is due the co-ordination of these researches, and the welding of his results into a doctrine to which the phlogistic theory ultimately succumbed. He burned phosphorus in air standing over mercury, and showed that (1) there was a limit to the amount of phosphorus which could be burned in the confined air, (2) that when no more phosphorus could be burned, one-fifth of the air had disappeared, (3) that the weight of the air lost was nearly equal to the difference in weight of the solids before and after the phosphorus was burned, (4) that the density of the residual air was less than that of ordinary air. The same results were obtained with lead and tin; and a more elaborate repetition indubitably established their correctness. He also showed that on heating mercury calx alone an "air" was liberated which differed from other "aeris," and was slightly heavier than ordinary air; moreover, the weight of the "air" set free from a given weight of the calx was equal to the weight taken up in forming the calx from mercury, and if the calx be heated with charcoal, the metal was recovered and a gas named "fixed air," the modern carbon dioxide, was formed. The former experiment had been performed by Scheele and Priestley, who had named the gas "phlogisticated air"; Lavoisier subsequently named it oxygen, regarding it as the "acid producer" (oxy, sour). The theory advocated by Lavoisier came to displace the phlogistic conception; but at first its acceptance was slow. Chemical literature was full of the phlogistic modes of expression—oxygen was "dephlogisticated air," nitrogen "phlogisticated air," &c.—and this tended to retard its promotion. Yet really the transition from the one theory to the other was simple, if it be necessary to change the "addition or loss of phlogiston" into the "loss or addition of oxygen." By his insistence upon the use of the balance as a quantitative check upon the masses involved in all chemical reactions, Lavoisier was enabled to establish by his own investigations and the results achieved by others the principle now known as the "conservation of mass." Matter can neither be created nor destroyed; however a chemical system be changed, the weights before and after are equal. 1 To him is also due a rigorous examination of the nature of elements and compounds; he held the same views that were later brought by Boyle, and with the same prophetic foresight predicted that some of the elements which he himself accepted might be eventually found to be compounds.

It is unnecessary in this place to recapitulate the many results which had accumulated by the end of the 18th century, or to discuss the labours and theories of individual workers since these receive attention under biographical headings; in this article only the salient features in the history of our science can be treated. The beginning of the 19th century was attended by far-reaching discoveries in the nature of the composition of compounds. Investigations proceeded in two directions:—(1) the nature of chemical affinity, (2) the laws of chemical combination. The first question has not yet been solved, although it has been speculated upon from the earliest times. The alchemists explained chemical action by means of such phrases as "like attracts like," substances being said to combine when one "loved" the other, and the reverse when it "hated" it. Boyle rejected this terminology, which was only strictly applicable to intelligent beings; and he used the word "affinity" as had been previously done by Stahl and others. The modern sense of the word, viz. the forces of attraction between all atoms of the same or different elements, which are fixed together (and also similar substances as is seen in di-, tri-, and polyatomic molecules), was introduced by Hermann Boerhaave, and made more precise by Sir Isaac Newton. The laws of chemical combination were solved, in a measure, by John Dalton, and the solution expressed as Dalton's "atomic theory." Lavoisier appears to have assumed that the composition of every chemical compound was constant, and the same opinion was the basis of much experimental inquiry at the hands of Joseph Louis Proust during 1801 to 1809, who vigorously combated the doctrine of Claude Louis Berthollet (Essai de statique chimique, 1803), viz. that fixed proportions of elements and compounds combine only under exceptional conditions, the general rule being that the composition of a compound may vary continuously between certain limits. 2 This controversy was unfinished when Dalton published the first part of his New System of Chemical Philosophy in 1808, although the per salvm theory was the most popular. 3

Chemical affinity.

1 This dictum was questioned by the researches of H. Landolt, Proust, and others. In a series of 75 reactions it was found that in 61 there was apparently a diminution in weight, but in 1988, after a more careful repetition and making allowance for all experimental errors, Landolt concluded that no change occurred (see chemical action).

2 The theory of Berthollet was essentially mechanical, and he attempted to prove that the course of a reaction depended not on affinities alone but also on the masses of the reacting components. In this respect his hypothesis has much in common with the law of mass-action developed at a much later date by the Swedish chemists Guldberg and Waage, and the American, Willard Gibbs (see chemical action). In his classical thesis Berthollet vigorously attacked the results deduced by Bergman, who had followed in his table of elective attractions the path traversed by Stahl and S. Geoffroy.
deduced the relative weight of the oxygen atom to be 6.5; from marsh gas and olefiant gas he deduced carbon = 4, there being one atom of carbon and two of hydrogen in the former and one atom of hydrogen to one of carbon in the latter; nitrogen had an equivalent of 5, and so on.1

The value of Dalton's generalizations can hardly be overestimated, notwithstanding the fact that in several cases they needed correction. The first step in this direction was effected by the co-ordination of Gay Lussac's observations on the combining volumes of gases. He discovered that gases always combined in volumes having simple ratios, and that the volume of the product had a simple ratio to the volumes of the reacting gases. For example, one volume of oxygen combined with two of hydrogen to form two volumes of steam, three volumes of hydrogen combined with one of nitrogen to give two volumes of ammonia, one volume of hydrogen combined with one of chlorine to give two volumes of hydrochloric acid. An immediate inference was that the Daltonian "atom" must have parts which enter into combination with parts of other atoms; in other words, there must exist two orders of particles, viz. (1) particles derived by limiting mechanical subdivision, the modern molecule, and (2) particles derived from the first class by chemical subdivision, i.e., particles which are incapable of existing alone, but may exist in combination. Additional evidence as to the structure of the molecule was discussed by Avogadro in 1811, and by Ampère in 1814. From the gas-laws of Boyle and J. A. C. Charles—viz. equal changes in temperature and pressure occasion equal changes in equal volumes of all gases and vapours—Avogadro deduced the law:—Under the same conditions of temperature and pressure, equal volumes of gases contain equal numbers of molecules; and he showed that the relative weights of the molecules are determined as the ratios of the weights of equal volumes, or densities. He established the existence of molecules and atoms as we have defined above, and stated that the number of atoms in the molecule is generally 2, but may be 4, 8, &c. We cannot tell whether his choice of the powers of 2 is accident or design.

Notwithstanding Avogadro's perspicuous investigation, and a similar exposition of the atom and molecule by A. M. Ampère, Berzelius, the views therein expressed were ignored both by their own and the succeeding generation. In place of the relative molecular weights, attention was concentrated on relative atomic or equivalent weights. This may be due in some measure to the small number of gaseous and easily volatile substances then known, to the attention which the study of the organic compounds received, and especially to the energetic investigations of J. J. Berzelius, who, fired with enthusiasm by the original theory of Dalton and the law of multiple proportions, determined the equivalents of combining ratios of many elements in an enormous number of compounds.2 He prosecuted his labours in this field for thirty years; as proof of his industry it may be mentioned that as early as 1819 he had determined the combining ratios of about two thousand simple and complex substances.

We may here notice the important chemical symbolism or notation introduced by Berzelius, which greatly contributed to the definite and convenient representation of chemical composition and the tracing of chemical reactions. The denotation of elements by symbols had been practised by the alchemists, and it is interesting to note that the symbols allotted to the well-known elements are identical with the astrological symbols of the sun and the other planets. Cold, the metal, had the symbol of the Sun, ☉; silver, the semiperfect metal, had the symbol of the Moon, ☽; copper, iron and antimony, the imperfect metals of the gold class, had the symbols of Venus ☉; Mars ☽; and the Earth ☾; tin and lead, the imperfect metals of the silver class, had the symbols of Jupiter ☽ and Saturn ☾; while mercury, the imperfect metal of both the gold and silver class, had the symbol of the planet, ☾. Torber Olof Bergman used an elaborate system in his Opuscula physica et chemica (1783); the elements received symbols composed of circles, arcs of circles, and lines, while certain class symbols, such as ⊙ for metals, + for alkalies, + for salts, + for calces, &c., were used. Compounds were represented by copulating smaller symbols, e.g. mercury calx was ☀, 4. Bergman's symbolism was obviously cumbrous, and the system used in 1782 by Lavoisier was equally abstruse, since the forms gave no clue as to composition; for instance water, oxygen, and nitric acid were ⊙, ⊙, and ⊙, the first three representing the gaseous oxides, and the last two the liquid oxides.

A great advance was made by Dalton, who, besides introducing simpler symbols, regarded the symbol as representing not only the element or compound but also one atom of that element or compound; in other words, his symbol denoted equivalent weights.3 This system, which permitted the correct representation of molecular composition, was adopted by Berzelius in 1814, who, having replaced the common signs of the elements by the number of atoms of the Latins names of the elements, represented a compound by placing a plus sign between the symbols of its components, and the number of atoms of each component (except in the case of only one atom) by the number of signs in the symbols. An example of the copper oxide was Cu + O, sulphur trioxide S + 3O. If two compounds combined, the + signs of the free compounds were discarded, and the number of atoms denoted by an Arabic index placed after the symbol, or by a horizontal bar, to denote the double atom (or molecule). Although the system of Berzelius has been modified and extended, its principles survive in the modern notation.

In the development of the atomic theory and the deduction of the atomic weights of elements and the formulae of compounds, Dalton's arbitrary rules failed to find complete acceptance. Berzelius objected to the hypothesis that if two elements form only one compound, then the atom combine one and one; and although he agreed with the foundation of simple as a truth, in representing a compound, he availed himself of other data in order to gain further information as to the structure of compounds. For example, at first he represented ferrous and ferric oxides by the formulae FeO, Fe₂O₃, and by the analogy of zinc and other basic oxides he regarded these substances as constituted similarly to FeO₂, and the acidic oxides alumina and chromium oxide as similar to FeO₂. He found, however, that chromic acid, which he had represented as CrO₃, neutralized a base containing 3 the

1 Dalton's atomic theory is treated in more detail in the article Atom.
2 Berzelius, however, appreciated the necessity of differentiating the atom and the molecule, and even urged Dalton to amend his doctrine, but without success.
3 The following symbols were also used by Bergman:

[[Symbols and their meanings provided here.]]

4 The following are the symbols employed by Dalton:

[[Symbols and their meanings provided here.]]

which represent in order, hydrogen, nitrogen, carbon, oxygen, phosphorus, sulphur, magnesia, lime, soda, potash, strontia, baryta, mercury; iron, zinc, copper, lead, silver, platinum, and gold were represented by circles enclosing the initial letter of the element.
quantity of oxygen. He inferred that chromic acid must contain only three atoms of oxygen, as did sulphuric acid $\text{SO}_4$; consequently chromic oxide, which contains half the amount of oxygen, must be $\text{Cr}_2\text{O}_3$, and hence ferric oxide must be $\text{Fe}_2\text{O}_3$.

The basic oxides must have the general formula $\text{MO}$. To these results he was aided by the law of isomorphism formulated by E. Mitscherlich in 1820; and he confirmed his conclusions by showing the agreement with the law of atomic heat formulated by Dulong and Petit in 1819.

While successfully investigating the solid elements and their compounds gravimetrically, Berzelius was guilty of several inconsistencies in his views on gases. He denied that gaseous atoms could have parts, although compound gases could. This attitude was due to his adherence to the "dualistic theory" of the structure of substances, which he deduced from electrochemical researches. From the behaviour of substances on electrolysis (q.v.) he assumed that all substances had two components, one bearing a negative charge, the other a positive charge. Combination was associated with the coalescence of these charges, and the nature of the resulting compound showed the nature of the residual electricity. For example, positive iron combined with negative oxygen to form positive ferrous oxide; positive sulphur combined with negative oxygen to form negative sulphuric acid; positive ferrous oxide combined with negative sulphuric acid to form neutral ferrous sulphate.

Berzelius elevated this theory to an important position in the history of our science. He recognized that if an elementary atom had parts, his theory demanded that these parts should carry different electric charges when they entered into reaction, and the products of the reaction should vary according as a positive or negative atom entered into combination. For instance if the reaction $2\text{H}_2\text{O} = \text{H}_2\text{O} + \text{H}_2\text{O}$ be true, the molecules of water should be different, for a negative oxygen atom would combine in one case, and a positive oxygen atom in the other. Hence the gaseous atoms of hydrogen and oxygen could not have parts. A second inconsistency was presented when he was compelled by the researches of Dumas to admit Avogadro's hypothesis; but here he would only accept it for the elementary gases, and denied it for other substances. It is to be noticed that J. B. Dumas did not adopt the best methods for emphasizing his discoveries. His terminology was vague and provoked caustic criticism from Berzelius; he assumed that all molecules contained two atoms, and consequently the atomic weights deduced from vapour density determinations of sulphur, mercury, arsenic, and phosphorus were quite different from those established by gravimetric and other methods. Chemists gradually tired of the notion of atomic weights on account of the uncertainty which surrounded them; and the suggestion made by W. H. Wollaston as early as 1814 to deal only with "equivalents," i.e. the amount of an element which can combine with or replace unit weight of hydrogen, came into favour, being adopted by L. Gmelin in his famous text-book.

Simultaneously with this discussion of the atom and molecule, great controversy was ranging over the positiveness or negativity of compounds. This subject is discussed in section IV., Organic Chemistry. The gradual accumulation of data referring to organic compounds brought in its train a revival of the discussion of atoms and molecules. A. Laurent and C. F. Gerhardt attempted a solution by investigating chemical reactions. They assumed the atom to be the smallest part of matter which can exist in combination, and the molecule to be the smallest part which can enter into a chemical reaction. Gerhardt found that reactions could be best followed if one assumed the molecular weight of an element or compound to be that weight which occupied the same volume as two unit weights of hydrogen, and this assumption led him to double the equivalents accepted by Gmelin, making $H=1$, $O=16$, and $C=12$, thereby agreeing with Berzelius, and also to halve the values given by Berzelius to many metals. Laurent generally agreed, except when the theory compelled the adoption of formulae containing fractions of atoms; in such cases he regarded the molecular weight as the weight occupying a volume equal to four unit weights of hydrogen. The bases upon which Gerhardt and Laurent founded their views were not sufficiently well grounded to lead to the acceptance of their results; Gerhardt himself returned to Gmelin's equivalents in his "Lehrbuch der Chemie" (1833) as they were in such general use.

In 1860 there prevailed such a confusion of hypotheses as to the atom and molecule that a conference was held at Karlsruhe to discuss the situation. At the conclusion of the sitting, Lothar Meyer obtained a paper written by Stanislas Cannizzaro in 1858 wherein was found the final link required for the determination of atomic weights. This link was the full extension of Avogadro's theory to all substances, Cannizzaro showing that chemical reactions in themselves would not suffice. He chose as his unit of reference the weight of an atom of hydrogen, i.e. the weight contained in a molecule of hydrochloric acid, thus differing from Avogadro who chose the weight of a hydrogen molecule. From a study of the free elements Cannizzaro showed that an element may have more than one molecular weight; for example, the molecular weight of sulphur varied with the temperature. And from the study of compounds he showed that each element occurred in a definite weight or in some multiple of this weight. He called this proportion the "atom," since it invariably enters compounds without division, and the weight of this atom is the atomic weight. This generalization was of great value inasmuch as it permitted the deduction of the atomic weight of a non-gasifiable element from a study of the densities of its gasifiable compounds.

From the results obtained by Laurent and Gerhardt and their predecessors it immediately followed that, while an element could have but one atomic weight, it could have several equivalent weights. From a detailed study of organic compounds Gerhardt had promulgated a "theory of types" which represented a fusion of the older radical and type theories. This theory brought together, as it were, the most varied compounds, and stimulated inquiry into many fields. According to this theory, an element in a compound had a definite saturation capacity, an idea very old in itself, being framed in the law of multiple proportions. These saturation capacities were assiduously studied by Sir Edward Frankland, who from the investigation, not of simple inorganic compounds, but of the organo-metallic derivatives, determined the kernel of the theory of valency. Frankland showed that any particular element preferentially combined with a definite number (which might vary between certain limits) of other atoms; for example, some atoms always combined with one atom of oxygen, some with two, while with others two atoms entered into combination with one of oxygen. If an element or radical combined with one atom of hydrogen, it was termed monovalent; if with two (or with one atom of oxygen, which is equivalent to two atoms of hydrogen) it was divalent, and so on. The same views were expressed by Cannizzaro, and also by A. W. von Hofmann, who materially helped the acceptance of the doctrine by the lucid exposition in his Lehrbuch der Chemie (1865).

The recognition of the quadrivalency of carbon by A. Kekulé was the forerunner of his celebrated benzene theory in particular, and of the universal application of structural formulæ to the representation of the most complex organic compounds equally lucidly as the representation of the simplest salts. Alexander Butlerow named the "structure theory," and contributed much to the development of the subject. He defined structure "as the manner of the mutual linking of the atoms in the molecule," but denied that any such structure could give information as to the orientation of the atoms in space. He regarded the chemical properties of a substance as due to (1) the chemical atoms composing it, and (2) the structure, and he asserted that while different compounds might have the same components (isomerism), yet only one compound could have a particular structure. Identity in properties necessitated identity in structure.

While the principle of varying valency laid down by Frankland is still retained, Butlerow's view that structure had no spatial significance has been modified. The researches of L. Pasteur,
CHEMISTRY

J. A. Le Bel, J. Wieliczenus, van't Hoff and others showed that substances having the same graphic formulæ vary in properties and reactions, and consequently the formulae need modification in order to exhibit these differences. Such isomerism, named stereo-
isomerism (q.v.), has been assiduously developed during recent years; it prevails among many different classes of organic compounds and many examples have been found in inorganic chemistry.

The theory of valency as a means of showing similarity of properties and relative composition became a dominant feature of chemical theory, the older hypotheses of types, radicals, &c. being more or less discarded. We have seen how its utilization in the "structure theory" permitted great clarification, and attempts were not wanting for the deduction of analogies or a periodicity between elements. Frankland had recognized the analogies existing between the chemical properties of nitrogen, phosphorus, arsenic and antimony, noting that they act as tri- or penta-valent. Carbon was joined with silicon, zirconium and titanium, while boron, being trivalent, was relegated to another group. A general classification of elements, however, was not realized by Frankland, nor even by Odling, who had also investigated the question from the valency standpoint. The solution came about by arranging the elements in the order of their atomic weights, tempering the arrangement with the results deduced from the theory of valencies and experimental observations. Many chemists contributed to the establishment of such a periodicity, the greatest advances being made by John Newlands in England, Lothar Meyer in Germany, and D. J. Mendeleeff in St. Petersburg. For the development of this classification see Element.

In the above sketch we have briefly treated the history of the main tendencies of our science from the earliest times to the establishment of the modern laws and principles. We have seen that the science took its origin in the arts practised by the Egyptians, and, having come under the influence of philosophers, it chose for its purpose the isolation of the quinque essentias, and subsequently the "art of making gold and silver." This spirit gave way to the physicians, who regarded "chemistry as the art of preparing medicines," a denomination which in turn succumbed to the arguments of Boyle, who regarded it as the "science of the composition of substances," a definition which adequately fits the science to-day. We have seen how his classification of substances into elements and compounds, and the definitions which he assigned to these species, have similarly been retained; and how Lavoisier established the law of the "conservation of mass," overthrew the prevailing phlogistic theory, and became the founder of modern chemistry by the overwhelming importance which he gave to the use of the balance.

The development of the atomic theory and its concomitants—the laws of chemical combination and the notion of atoms and equivalents—at the hands of Dalton and Berzelius, the extension to the modern theory of the atom and molecule, and to atomic and molecular weights by Avogadro, Ampère, Dumas, Laurent, Gerhardt, Cannizzaro and others, have been noted. The structure of the molecule, which mainly followed investigations in organic chemistry, especially from 1840 onwards, and the conception of valency, and finally the periodic law, have also been shown in their chronological order. The principles outlined above constitute the foundations of our science; and although it may happen that experiments may be made with which they appear to be not in complete agreement, yet in general they constitute a body of working hypotheses of inestimable value.

Chemical Education.—It is remarkable that systematic instruction in the theory and practice of chemistry only received earnest attention in our academic institutions during the opening decades of the 19th century. Although for a long time lecturers and professors had been attached to universities, generally their duties had also included the study of physics, mineralogy and other subjects, with the result that chemistry received scanty encouragement. Of practical instruction there was none other than that to be gained in a few private laboratories and in the shops of apothecaries. The necessity for experimental demonstration and practical instruction, in addition to academic lectures, appears to have been urged by the French chemists L. N. Vauquelin, Gay Lussac, Thénard, and more especially by A. F. Fourcroy and G. F. Rouelle, while in England Humphry Davy expounded the same idea in the experimental demonstrations which gave his lectures their brilliant charm. But the real founder of systematic instruction in our science was Justus von Liebig, who, having accepted the professorship at Giessen in 1824, made his chemical laboratory and course of instruction the model of all others. He emphasized that the practical training should include (1) the qualitative and quantitative analysis of mixtures, (2) the preparation of substances according to established methods, (3) original research—a course which has been generally adopted. The pattern set by Liebig at Giessen was adopted by F. Wöhler at Göttingen in 1856, by W. Bunsen at Marburg in 1840, and by O. L. Erdmann at Leipzig in 1843; and during the 'fifties and 'sixties many other laboratories were founded. A new era followed the erection of the laboratories at Bonn and Berlin according to the plans of A. W. von Hofmann in 1857, and of that at Leipzig, designed by Kolbe in 1868. We may also mention the famous laboratory at Munich designed by A. von Baeyer in 1875.

In Great Britain the first public laboratory appears to have been opened in 1817 by Thomas Thomson at Glasgow. But the first important step in providing means whereby students could systematically study chemistry was the foundation of the College of Chemistry in 1845. This institution was taken over by the Government in 1853, becoming the Royal College of Chemistry, and incorporated with the Royal School of Mines; in 1881 the names were changed to the Normal School of Science and Royal School of Mines, and again in 1890 to the Royal College of Science. In 1907 it was incorporated in the Imperial College of Science and Technology. Under A. W. von Hofmann, who designed the laboratories and accepted the professorship in 1845 at the instigation of Prince Albert, and under his successor (in 1864) Sir Edward Frankland, this institution became one of the most important centres of chemical instruction. Oxford and Cambridge sadly neglected the erection of convenient laboratories for many years, and consequently we find technical schools and other universities having a far better equipment and offering greater facilities. In the provinces Victoria University at Manchester exercised the greater impetus, numbering among its professors Sir W. H. Perkin and Sir Henry Roscoe.

In America public laboratory instruction was first instituted at Yale College during the professorship of Benjamin Silliman. To the great progress made in recent years F. W. Clarke, W. Gibbs, E. W. Morley, Ira Remsen, and T. W. Richards have especially contributed.

In France the subject was almost entirely neglected until late in the 19th century. The few laboratories existing in the opening decades were ill-equipped, and the exorbitant fees constituted a serious bar to general instruction, for these institutions received little government support. In 1869 A. Wurtz reported the existence of only one efficient laboratory in France, namely the École Normale Superieure, under the direction of H. Sainte Claire Deville. During the succeeding years it has become one of the most important subjects in the curriculum of technical schools and universities, and at the present time no general educational institution is complete until it has its full equipment of laboratories and lecture theatres.

Chemical Literature.—The growth of chemical literature since the publication of Lavoisier's famous Traité de chimie in 1789, and of Berzelius' Lehrbuch der Chemie in 1818-1819, has been enormous. The numerous works later followed by Thénard, Liebig, Streeker, Wöhler and many others, including Thomas Graham, upon whose Elements of Chemistry was founded Otto's famous Lehrbuch der Chemie, to which H. Kopp contributed a theoretical section, and Kolbe and Buhl and Zinamin the physico-chemical. Organic chemistry was especially developed by the publication of Gerhardt's Traité de chimie organique in 1853-1856, and of Kekulé's Lehrbuch der organischen Chemie in 1862-1882. General theoretical and physical chemistry was treated with conspicuous acumen by Lothar Meyer in his Moderne Theorien, by W. Ostwald in his Lehrbuch der allgemeinen Chemie (1884-1887), and by Nernst in his Theoretische Chemie. In English, Roscoe and Schorlemmer's Treatise on Chemistry is a standard work; it records...
PRINCIPLES

CHEMISTRY

a successful attempt to state the theories and facts of chemistry, not in condensed epitomes, but in an easily read form. The *Traité de chimie minérale*, edited by H. Moissan, and the *Handbuch der anorganischen Chemie*, edited by Abegg, are of the same type. Of Dammann’s *Handbuch der anorganischen Chemie* and P. Bellonnet’s *Handbuch der organischen Chemie* are invaluable works of reference. Of the earlier encyclopaedias we may notice the famous *Handwörterbuch der reinen und angewandten Chemie*, edited by Liebig; *Fremy’s Encyclopædia of Chemistry*, Volumes I and II, and the *Annales de chimie et de physique*, founded in 1839, with the *Cours de chimie*, by the late Sir W. Crookes in 1866, may also be noted. In America the chief periodical is the *American Chemical Journal*, founded in 1879, with the *Jahrbuch für praktische Chemie*, founded by Erdmann in 1834, the *Zeitschrift für anorganische Chemie* and the *Jahrbuch für angewandte Chemie*. In France, the most important journals are the *Annales de chimie and physique*, founded in 1789 with the *Annuaire des chimie* and the *Comptes rendus*, published weekly by the Académie française since 1835.

II. GENERAL PRINCIPLES

The substances with which the chemist has to deal admit of classification into elements and compounds. Of the former about eighty may be regarded as well characterized, although many more have been described.

**Elements.**—The following table gives the names, symbols and atomic weights of the perfectly characterized elements:

The elements are usually divided into two classes, the metallic and the non-metallic elements; the following are classed as non-metals, and the remainder as metals:

- **Hydrogen**
- **Oxygen**
- **Boron**
- **Neon**
- **Chlorine**
- **Sulphur**
- **Carbon**
- **Krypton**
- **Bromine**
- **Selenium**
- **Silicon**
- **Xenon**
- **Iodine**
- **Tellurium**
- **Phosphorus**
- **Helium**
- **Fluorine**
- **Nitrogen**
- **Argon**

Of these, hydrogen, chlorine, fluorine, oxygen, nitrogen, argon, neon, krypton, xenon and helium are gases, bromine is a liquid, and the remainder are solids. All the metals are solids at ordinary temperatures with the exception of mercury, which is liquid.

The metals are mostly bodies of high specific gravity; they exhibit a peculiar brilliance or metallic lustre, and they are good conductors of heat and electricity. The non-metals, on the other hand, are mostly bodies of low specific gravity, and bad conductors of heat and electricity, and do not exhibit metallic lustre. The non-metallic elements are also sometimes termed metalloids, but this appellation, which signifies metal-like substances (Gr. ἂνθος, like), strictly belongs to certain elements which do not possess the properties of the true metals, although they more closely resemble them than the non-metals in many respects; thus, selenium and tellurium, which are closely allied to sulphur in their chemical properties, although bad conductors of heat and electricity, exhibit metallic lustre and have relatively high specific gravities. But when the properties of the elements are carefully contrasted together it is found that no strict line of demarcation can be drawn dividing them into two classes; and if they are arranged in a series, those which are most closely allied in properties being placed next to each other, it is observed that there is a more or less regular alteration in properties from term to term in the series.

When binary compounds, or compounds of two elements, are decomposed by an electric current, the two elements make their appearance at opposite poles. Those elements which are disengaged at the negative pole are termed electro-positive, or positive, or balsy elements, whilst those disengaged at the positive pole are termed electro-negative, or negative, or chlorous elements. But the difference between these two classes of elements is one of degree only, and they gradually merge into each other; moreover the electric relations of elements are not absolute, but vary according to the state of combination in which they exist, so that it is just as impossible to divide the elements into two classes according to this property as it is to separate them into two distinct classes of metals and non-metals.

The following, however, are negative towards the remaining elements which are more or less positive. The tendency of positive elements to unite with positive elements, or of negative elements to unite with negative elements, is much less than that of positive elements to unite with negative elements, and the greater the difference in properties between two elements the more powerful is their affinity for each other. Thus, the affinity of hydrogen and oxygen for each other is extremely powerful, much heat being developed by the combination of these two elements; when binary compounds of oxygen are decomposed by the electric current, the oxygen invariably appears at the positive pole, being negative to all other elements, but the hydrogen of hydrogen compounds is always disengaged at the negative pole. Hydrogen and oxygen are, therefore, of very opposite natures, and this, is well illustrated by the circumstance that oxygen combines with very few exceptions with all the remaining elements, whilst compounds of only a limited number with hydrogen have been obtained.

**Compounds.**—A chemical compound contains two or more
elements; consequently it should be possible to analyse it, i.e., separate it into its components, or to synthesise it, i.e., build it up from its components. In general, a compound has properties markedly different from those of the elements of which it is composed.

Laws of Chemical Combination.—A molecule may be defined as the smallest part of a substance which can exist alone; an atom as the smallest part of a substance which can exist in combination. The molecule of every compound must obviously contain at least two atoms, and generally the molecules of the elements are also polyatomic, the elements with monatomic molecules (at moderate temperatures) being mercury and the gases of the argon group. The laws of chemical combination are as follows:—

1. Law of Definite Proportions.—The same compound always contains the same elements combined together in the same mass proportion. Silver chloride, for example, in whatever manner it may be prepared, invariably consists of chlorine and silver in the proportions by weight of 35:45 parts of the former and 107:93 parts of the latter.

2. Law of Multiple Proportions.—When the same two elements combine together to form more than one compound, the different masses of one of the elements which unite with a constant mass of the other, bear a simple ratio to one another. Thus, a part by weight of hydrogen unites with 8 parts by weight of oxygen, forming water, and with 16 or 8 × 2 parts of oxygen, forming hydrogen peroxide. Again, in nitrous oxide we have a compound of 8 parts by weight of oxygen and 14 of nitrogen; in nitric oxide a compound of 16 or 8 × 2 parts of oxygen and 14 of nitrogen; in nitrous anhydride a compound of 24 or 8 × 3 parts of oxygen and 14 of nitrogen; in nitric peroxide a compound of 32 or 8 × 4 parts of oxygen and 14 of nitrogen; and lastly, in nitric anhydride a compound of 40 or 8 × 5 parts of oxygen and 14 of nitrogen.

3. Law of Reciprocal Proportions.—The masses of different elements which combine separately with one and the same mass of another element, are either the same as, or simple multiples of, the masses of these different elements which combine with each other. For instance, 35:45 parts of chlorine and 79:96 parts of bromine combine with 107:93 parts of silver; and when chlorine and bromine unite it is in the proportion of 35:45 parts of the former to 70:96 parts of the latter. Iodine unites with silver in the proportion of 126:97 parts to 107:93 parts of the latter, but it combines with chlorine in two proportions, viz., in the proportion of 126:97 parts either to 35:45 or to three times 35:45 parts of chlorine.

There is a fourth law of chemical combination which only applies to gases. This law states that gases combine with one another in simple proportions by volume, and the volume of the product (if gaseous) has a simple ratio to the volumes of the original mixtures; in other words, the densities of gases are simply related to their combining weights.

Nomenclature.—If a compound contains two atoms it is termed a binary compound, if three a ternary, if four a quaternary, and so on. Its systematic name is formed by replacing the last syllable of each of the two elements by -ide and prefixing the name of the other element. For example, compounds of oxygen are oxides, of chlorine, chlorides, and so on. If more than one compound be formed from the same two elements, the difference is shown by prefixing such words as mono-, di-, tri-, sesqui-, per-, sub-, &c., to the last part of the name, or the suffixes -ous and -ic may be appended to the name of the first element. For example take the oxides of nitrogen, NO, NO₂, NO₃, NO₄; these are known respectively as nitrous oxide, nitric oxide, nitrogen trioxide, nitrogen peroxide and nitrogen pentoxide. The affixes -ous and sub- refer to the compounds containing more of the positive element, -ic and per- to those containing less.

An acid (q.v.) is a compound of hydrogen, which element can be replaced by metals, the hydrogen being liberated, giving substances named salts. An alkali or base is a substance which neutralizes an acid with the production of salts but with no evolution of hydrogen. A base may be regarded as water in which part of the hydrogen is replaced by a metal, or by a radical which behaves as a metal. (The term radical is given to a group of atoms which persist in chemical changes, behaving as if the group were an element; the commonest is the ammonium group, NH₄, which forms salts similar to the salts of sodium and potassium.) If the acid contains no oxygen it is a hydrazic, and its systematic name is formed from the prefix hydrazo- and the name of the other element or radical, the last syllable of which has been replaced by the termination -ic. For example, the acid formed by hydrogen and chlorine is termed hydrochloric acid (and sometimes hydrogen chloride). If an acid contains oxygen it is termed an oxyacid. The nomenclature of acids follows the same general lines as that for binary compounds. If one acid be known its name is formed by the termination -ic, e.g. carbonic acid; if two, the one containing the less amount of oxygen takes the termination -ous and the other the termination -ic, e.g. nitrous acid, HNO₃, nitric acid, HNO₄. If more than two be known, the one inferior in oxygen content has the prefix hypo- and the termination -ous, and the one superior in oxygen content has the prefix per- and the termination -ic. This is illustrated in the four oxyacids of chlorine, HClO, HClO₂, HClO₃, HClO₄, which have the names hypochlorous, chlorous, chloric and perchloric acids. An acid is said to be monobasic, dibasic, tribasic, &c., according to the number of replaceable hydrogen atoms; thus HNO₂ is monobasic, sulphuric acid H₂SO₄ dibasic, phosphoric acid H₃PO₄ tribasic.

An acid terminating in -ous forms a salt ending in -ite, and an oxyacid ending in -ic forms a salt ending in -ate. Thus the chlorine oxyacids enumerated above form salts named respectively hypochlorites, chlorites, chlorates and perchlorates. Salts formed from hydrazics terminate in -ide, following the rule for binary compounds. An acid salt is one in which the whole amount of hydrogen has not been replaced by metal; a normal salt is one in which all the hydrogen has been replaced; and a basic salt is one in which part of the acid of the normal salt has been replaced by oxygen.

Chemical Formulas.—Opposite the name of each element in the second column of the above table, the symbol is given which is always employed to represent it. This symbol, however, not only represents the particular element, but a certain definite quantity of it. Thus, the letter H always stands for 1 atom or 1 part by weight of hydrogen, the letter N for 1 atom or 14 parts of nitrogen, and the symbol Cl for 1 atom or 35:5 parts of chlorine. Compounds are in like manner represented by writing the symbols of their constituent elements side by side, and if more than one atom of each element be present, the number is indicated by a numeral placed on the right of the symbol of the element either below or above the line. Thus, hydrochloric acid is represented by the formula HCl, that is to say, it is a compound of an atom of hydrogen with an atom of chlorine, or of 1 part by weight of hydrogen with 35:5 parts by weight of chlorine; again, sulphuric acid is represented by the formula H₂SO₄, which is a statement that it consists of 2 atoms of hydrogen, 1 of sulphur, and 4 of oxygen, and consequently of certain relative weights of these elements. A figure placed on the right of a symbol only affects the symbol to which it is attached, but when figures are placed in front of several symbols all are affected by it, thus 2H₂SO₄ means H₂SO₄ taken twice.

The distribution of weight in chemical change is readily expressed in the form of equations by the aid of these symbols; the equation

\[2\text{HCl} + \text{Zn} = \text{ZnCl}_2 + \text{H}_2\]

for example, is to be read as meaning that from 73 parts of hydrochloric acid and 65 parts of zinc, 136 parts of zinc chloride and 2 parts of hydrogen are produced. The + sign is invariably employed in this way, to express combination or action upon, the meaning usually attached to the use of the sign = being that from such and such bodies such and such other bodies are formed.

* Approximate values of the atomic weights are employed here.
it is formed, and the behaviour it will exhibit under various circumstances. Before explaining these formulae it will be necessary, however, to consider the differences in combining power exhibited by the various elements.

Valency.—It is found that the number of atoms of a given element, of chlorine, for example, which unite with an atom of each of the other elements is very variable. Thus, hydrogen unites with but a single atom of chlorine, zinc with two, boron with three, silicon with four, phosphorus with five and tungsten with six. Those elements which are equivalent in combining or displacing power to a single atom of hydrogen are said to be univalent or monad elements; whilst those which are equivalent to two atoms of hydrogen are termed bivalent or dyad elements; and those equivalent to three, four, five or six atoms of hydrogen triad, tetrad, pentad or hexad elements. But not only is the combining power or valency (atomicity) of the elements different, it is also observed that one element may combine with another in several proportions, or that its valency may vary; for example, phosphorus forms two chlorides represented by the formulae PC1 and PC12, nitrogen the series of oxides represented by the formulae NO, NO2, NO3, whilst the molecule of acetic acid, CH3COOH, is divided into two parts, the formula of each of the parts being CH3 and COOH.

In explanation of these facts it is supposed that each element has a certain number of "units of affinity," which may be entirely, or only in part, engaged when it enters into combination with other elements; and in those cases in which the entire number of units of affinity are not engaged by other elements, it is supposed that those which are thus disengaged neutralize each other, as it were. For example, in phosphorus pentachloride the five units of affinity possessed by the phosphorus atom are satisfied by the five monad atoms of chlorine, but in the trichloride two are disengaged, and, it may be supposed, satisfy each other. Compounds in which all the units of affinity of the contained elements are engaged are said to be saturated, whilst in all the others in which the affinities of the contained elements are not all engaged by other elements are said to be unsaturated. According to this view, it is necessary to assume that, in all such compounds, two, or even some number of affinities are disengaged; and also that all elements which combine with an even number of monad atoms cannot combine with an odd number, and vice versa,—in other words, that the number of units of affinity active in the case of any given element must be always either an even or an odd number, and that it cannot be at one time an even and at another an odd number. There are, however, a few remarkable exceptions to this "law." Thus, it must be supposed that in nitric oxide, NO, an odd number of affinities are disengaged, since a single atom of d Yad oxygen is united with a single atom of nitrogen, which in all its compounds with other elements acts either as a triad or pentad. When nitric peroxide, N2O3, is converted into gas, it decomposes, and at about 180° C. its vapour entirely consists of molecules of the composition NO2; while at temperatures between this and 0° C. it consists of a mixture in different proportions of the two kinds of molecules, N2O3 and NO2. The oxides NO2 must be regarded as another instance of a compound in which an odd number of affinity is disengaged; the other disengaged elements are disengaged, since it contains two atoms of dyad oxygen united with a single atom of triad or pentad nitrogen. Again, when tungsten hexachloride is converted into vapour it is decomposed into chlorine and a pentachloride, having a normal vapour density, but as in the majority of its compounds tungsten acts as a hexad, we apparently must regard its pentachloride as a compound in which an odd number of free affinities are disengaged. Hitherto no explanation has been given of these exceptions which appears to be a law of almost universal application, viz. that the sum of the units of affinity of all the atoms in a compound is an even number.

The number of units of affinity active in the case of any particular element is largely dependent, however, upon the nature of the element or elements with which it is associated. Thus, an atom of iodine only combines with one of hydrogen,
CHEMISTRY

Oxygen, and thus also oxonium the Group, Ca, valency. Helium, attached of phosphorus, with only three atoms of hydrogen, but with five of chlorine, or with four of hydrogen and one of iodine; and the chlorides corresponding to the higher oxides of lead, nickel, manganese and arsenic, PbO, NiO, MnO and AsO do not exist as stable compounds, but the lower chlorides, PbCl₂, NiCl₂, MnCl₂ and AsCl₂ are very stable.

The valency of an element is usually expressed by dashes or Roman numerals placed on the right of its symbol, thus: H', O, B<sup>+</sup>, C<sup>+</sup>, P<sup>+</sup>, Mo<sup>+</sup>; but in constructing graphic formulæ the symbols of the elements are written with as many lines attached to each symbol as the element which it represents has units of affinity.

The periodic law (see Element) permits a grouping of the elements according to their valency as follows: Group I.: the alkali metals Li, Na, K, Rb, Cs, and also Ag, monovalent; Cu, monovalent and divalent; Au, monovalent and trivalent. Group II.: the alkaline earth metals Ca, Sr, Ba, and also Be (G), Mg, Zn, Cd, divalent; Hg, monovalent and divalent. Group III.: B, trivalent; Al, trivalent, but possibly also tetra- or penta-valent; Ga, divalent and trivalent; In, mono-, di- and tri-valent; TI, monovalent and trivalent. Group IV.: C, Si, Ge, Zr, Th, tetravalent; Ti, tetravalent and hexavalent; Sn, Pb, divalent and tetravalent; Ce, trivalent and tetravalent. Group V.: N, trivalent and pentavalent, but divalent in nitric oxide; F, As, Sb, Bi, trivalent and pentavalent, the last being possibly divalent in BiO and BiCl₂. Group VI.: O, usually divalent, but tetravalent and possibly hexavalent in oxonium and other salts; S, Se, Te, di-, tetra- and hexa-valent; Cr, di-, tri- and hexa-valent; Mo, W, di-, tri-, tetra-, penta- and hexa-valent. Group VII.: H (?), monovalent; the halogens F, Cl, Br, I, usually monovalent, but possibly also tri- and pentavalent; Mn, divalent and trivalent, and possibly hexavalent in permanganates. Group VIII.: Fe, Co, divalent and trivalent; Ni, divalent; Os, Ru, hexavalent and octavalent; Pd, Pt, divalent and tetravalent; Ir, tri-, tetra- and hexa-valent. (See also Valency.)

**Constitutional Formulæ.**—Graphic or constitutional formulæ are employed to express the manner in which the constituent atoms of compounds are associated together; for example, the tetroxide of sulphur is usually regarded as a compound of an atom of hexad sulphur with three atoms of dyad oxygen, and this hypothesis is illustrated by the graphic formulæ:

\[ O = S < O \]

When this oxide is brought into contact with water it combines with it forming sulphuric acid, H₂SO₄.

In this compound only two of the oxygen atoms are wholly associated with the sulphur atom, each of the remaining oxygen atoms being united by one of its affinities to the sulphur atom, and by the remaining affinity to an atom of hydrogen; thus—

\[ H - O - S < O \]

The graphic formula of a sulphate is readily deduced by remembering that the hydrogen atoms are partially or entirely replaced. Thus acid sodium sulphate, normal sodium sulphate, and zinc sulphate have the formulæ:

\[ NaO - S < O \]

Again, the reactions of acetic acid, C₂H₅O₂, show that the four atoms of hydrogen which it contains have not all the same function, and also that the two atoms of oxygen have different functions; the graphic formulæ which we are led to assign to acetic acid, viz.

\[ H - C < O - H \]

serves in a measure to express this, three of the atoms of hydrogen being represented as associated with one of the atoms of carbon, whilst the fourth atom is associated with an atom of oxygen which is united by a single affinity to the second atom of carbon, to which, however, the second atom of oxygen is united by both of its affinities. It is not to be supposed that there are any actual bonds of union between the atoms; graphic formulæ such as these merely express the hypothesis that certain of the atoms in a compound are united directly within the sphere of attraction of certain other atoms, and only indirectly within the sphere of attraction of others,—an hypothesis to which chemists are led by observing that it is often possible to separate a group of elements from a compound, and to displace it by other elements or groups of elements.

Rational formulæ of a much simpler description than these graphic formulæ are generally employed. For instance, sulphuric acid is usually represented by the formulæ SO₄(OH)₂, which indicates that it may be regarded as a compound of the group SO₄ with twice the group OH. Each of these OH groups is equivalent in combining or displacing power to a monad element, since it consists of an atom of dyad oxygen associated with a single atom of monad hydrogen, so that in this case the SO₄ group is equivalent to an atom of a dyad element. This formula for sulphuric acid, however, merely represents such facts as that it is possible to displace an atom of hydrogen and an atom of oxygen in sulphuric acid by a single atom of chlorine, thus forming the compound SO₂Cl₂; and that by the action of water on the compound SO₃Cl₂ twice the group OH, or water minus an atom of hydrogen, is introduced in place of the two monad atoms of chlorine—

\[ SO₃Cl₂ + 2H₂O = SO₄(OH)₂ + 2Cl⁻ \]

Water. Sulphuric acid.

Constitutional formulæ like these, in fact, are nothing more than symbolic expressions of the character of the compounds which they represent, the arrangement of symbols in a certain definite manner being understood to convey certain information with regard to the compounds represented.

Groups of two or more atoms like SO₂ and OH, which are capable of playing the part of elementary atoms (that is to say, which can be transferred from compound to compound), are termed compound radicals, the elementary atoms being simple radicals. Thus, the atom of hydrogen is a monad simple radical, the atom of oxygen a dyad simple radical, whilst the group OH is a monad compound radical.

It is often convenient to regard compounds as formed upon certain types; alcohol, for example, may be said to be a compound formed upon the water type, that is to say, a compound formed from water by displacing one of the atoms of hydrogen by the group of elements C₂H₅, thus—

\[ O \]

Water

\[ O / C₂H₅ \]

Alcohol.

Constitutional formulæ become of preponderating importance when we consider the more complicated inorganic and especially organic compounds. Their full significance is treated in the section of this article dealing with organic chemistry, and in the articles Isomerism and Stereo-isomerism.

**Chemical Action.**—Chemical change or chemical action may be said to take place whenever changes occur which involve an alteration in the composition of substances; and that they are the result of the action of agents such as heat, electricity or light, or of two or more elements or compounds upon each other.

Three kinds of changes are to be distinguished, viz. changes which involve combination, changes which involve decomposition or separation, and changes which involve at the same time both decomposition and combination. Changes of the first and second kind, according to our views of the constitution of molecules, are probably of very rare occurrence; in fact, chemical action appears almost always to involve the occurrence of both these kinds of change, for, as already pointed out, we must assume that the molecules of hydrogen, oxygen and several other elements are diatomic, or that they consist of two atoms. Indeed, it appears probable that with few exceptions the elements
are all compounds of similar atoms united together by one or more units of affinity, according to their valencies. If this be the case, however, it is evident that there is no real distinction between the reactions which take place when two elements combine together and when an element in a compound is displaced by another. The combination, as it is ordinarily termed, of chlorine with hydrogen, and the displacement of iodine in potassium iodide by the action of chlorine, may be cited as examples; if these reactions are represented, as such reactions very commonly are, by equations which merely express the relative weights of the bodies which enter into reaction, and of the products, thus—

$$\text{H} + \text{Cl}_2 \rightarrow \text{HCl}.$$  

$$\text{KI} + \text{Cl}_2 = \text{KCl} + \text{I}_2.$$  

They appear to differ in character; but if they are correctly represented by molecular equations, or equations which express the relative number of molecules which enter into reaction and which result from the reaction, it will be obvious that the character of the reaction is substantially the same in both cases, and that both are instances of the occurrence of what is ordinarily termed double decomposition—

$$\text{H}_2 + \text{Cl}_2 = 2\text{HCl}.$$  

$$2\text{KI} + \text{Cl}_2 = 2\text{KCl} + \text{I}_2.$$  

In all cases of chemical change energy in the form of heat is either developed or absorbed, and the amount of heat developed or absorbed in a given reaction is as definite as are the weights of the substance engaged in the reaction. Thus, in the production of hydrochloric acid from hydrogen and chlorine 22,000 calories are developed; in the production of hydrobromic acid from hydrogen and bromine, however, only 8440 calories are developed; and in the formation of hydrobromic acid from hydrogen and iodine 6040 calories are absorbed.

This difference in behaviour of the three elements, chlorine, bromine and iodine, which in many respects exhibit considerable resemblance, may be explained in the following manner. We may suppose that in the formation of gaseous hydrochloric acid from gaseous chlorine and hydrogen, according to the equation

$$\text{H}_2 + \text{Cl}_2 \rightarrow \text{HCl} + \text{HCl},$$

a certain amount of energy is expended in separating the atoms of hydrogen in the hydrogen molecule, and the atoms of chlorine in the chlorine molecule, from each other; but that heat is developed by the combination of the hydrogen atoms with the chlorine atoms, and that, as more energy is developed by the union of the atoms of hydrogen and chlorine than is expended in separating the hydrogen atoms from each other and the chlorine atoms from each other, the result of the action of the two elements upon each other is the development of heat,—the amount finally developed in the reaction being the difference between that absorbed in decomposing the elementary molecules and that developed by the combination of the atoms of chlorine and hydrogen. In the formation of gaseous hydrobromic acid from liquid bromine and gaseous hydrogen—

$$\text{H}_2 + \text{Br}_2 = \text{HBr} + \text{HBr},$$

in addition to the energy expended in decomposing the hydrogen and bromine molecules, energy is also expended in converting the liquid bromine into the gaseous condition, and probably less heat is developed by the combination of bromine and hydrogen than by the combination of chlorine and hydrogen, so that the amount of heat finally developed is much less than is developed in the formation of hydrochloric acid. Lastly, in the production of gaseous hydriodic acid from hydrogen and solid iodine—

$$\text{H}_2 + \text{I}_2 = \text{HI} + \text{HI},$$

so much energy is expended in the decomposition of the hydrogen and iodine molecules and in the conversion of the iodine into the gaseous condition, that the heat which it may be supposed is developed by the combination of the hydrogen and iodine atoms is insufficient to balance the expenditure, and the final result is therefore negative; hence it is necessary in forming hydriodic acid from its elements to apply heat continuously.

These compounds also afford examples of the fact that, generally speaking, those compounds are most readily formed, and are most stable, in the formation of which the most heat is developed. Thus, chlorine enters into reaction with hydrogen, and removes hydrogen from hydrogenized bodies, far more readily than bromine; and hydrochloric acid is a far more stable substance than hydrobromic acid, hydriodic acid being greatly inferior even to hydrobromic acid in stability. Compounds formed with the evolution of heat are termed exothermic, while those formed with an absorption are termed endothermic. Explosives are the commonest examples of endothermic compounds.

When two substances which by their action upon each other develop much heat enter into reaction, the reaction is usually complete without the employment of an excess of either; for example, when a mixture of hydrogen and oxygen, in the proportions to form water—

$$2\text{H}_2 + \text{O}_2 = 2\text{OH}_2,$$

is exploded, it is entirely converted into water. This is also the case if two substances are brought together in solution, by the action of which upon each other a third body is formed which is insoluble in the solvent employed, and which also does not tend to react upon any of the substances present; for instance, when a solution of a chlorine is added to a solution of silver nitrate, insoluble silver chloride is precipitated, and almost the whole of the silver is removed from solution, even if the amount of the chloride employed be not in excess of that theoretically required.

But if there be no tendency to form an insoluble compound, or one which is not liable to react upon any of the other substances present, this is no longer the case. For example, when a solution of a ferric salt is added to a solution of potassium thiocyanate, a deep red coloration is produced, owing to the formation of ferric thiocyanate. Theoretically the reaction takes place in the case of ferric nitrate in the manner represented by the equation

$$\text{Fe(NO}_3)_3 + 3\text{KCN}_3 = \text{Fe(CNS)}_3 + 3\text{KNO}_3;$$

but it is found that even when more than sixty times the amount of potassium thiocyanate required by this equation is added, a portion of the ferric nitrate still remains unconverted, doubtless owing to the occurrence of the reverse change—

$$\text{Fe(CNS)}_3 + 3\text{KNO}_3 = \text{Fe(NO}_3)_3 + 3\text{KCN}_3.$$

In this, as in most other cases in which substances act upon one another under such circumstances that the resulting compounds are free to react, the extent to which the different kinds of action which may occur take place is dependent upon the mass of the substances present in the mixture. As another instance of this kind, the decomposition of bismuth chloride by water may be cited. If a very large quantity of water be added, the chloride is entirely decomposed in the manner represented by the equation—

$$\text{BiCl}_3 + \text{OH}_2 = \text{BiOCl} + 2\text{HCl},$$

Bismuth chloride. Bismuth oxychloride.

the oxychloride being precipitated; but if smaller quantities of water be added the decomposition is incomplete, and it is found that the extent to which decomposition takes place is proportional to the quantity of water employed, the decomposition being incomplete, except in presence of large quantities of water, because of the occurrence of the reverse action—

$$\text{BiOCl} + 2\text{HCl} = \text{BiCl}_3 + \text{OH}_2.$$

Chemical change which merely involves simple decomposition is thus seen to be influenced by the masses of the reacting substances and the presence of the products of decomposition; in other words the system of reacting substances and resultants form a mixture in which chemical action has apparently ceased, or the system is in equilibrium. Such reactions are termed reversible (see Chemical Action).
III. INORGANIC CHEMISTRY

Inorganic chemistry is concerned with the descriptive study of the elements and their compounds, except those of carbon. Reference should be made to the separate articles on the different elements and the more important compounds for their preparation, properties and uses. In this article the development of this branch of the science is treated historically.

The earliest discoveries in inorganic chemistry are to be found in the metallurgy, medicine and chemical arts of the ancients. The Egyptians obtained silver, iron, copper, lead, zinc and tin, either pure or as alloys, by smelting the ores; mercury is mentioned by Theophrastus (c. 300 B.C.). The manufacture of glass, also practised in Egypt, demanded a knowledge of sodium or potassium carbonates; the former occurs as an efflorescence on the shores of certain lakes; the latter was obtained from wood ashes. Many substances were used as pigments: Pliny records white lead, cinnabar, verdigris and red oxide of iron; and the preparation of coloured glasses and enamels testifies to the uses to which these and other substances were put. Salts of ammonium were also known; we alum was used as a mordant in dyeing. Many substances were employed in ancient medicine: galena was the basis of a valuable Egyptian cosmetic and drug; the arsenic sulphides, realgar and orpiment, litharge, alum, saltpetre, iron rust were also used. Among the Arabian and later alchemists we find attempts made to collate compounds by specific properties, and it is to these writers that we are mainly indebted for such terms as "alkali," "sal," &c. The mineral acids, hydrochloric, nitric and sulphuric acids, and also aqua regia (a mixture of hydrochloric and nitric acids) were discovered, and the vitriols, alum, saltpetre, sal-ammoniac, ammonium carbonate, silver nitrate (lunar caustic) became better known.

The compounds of mercury attracted considerable attention, mainly on account of their medicinal properties; mercuric oxide and corrosive sublimate were known to pseudo-Geber, and the nitrate and basic sulphate to "Basil Valentine." Antimony and its compounds formed the subject of an elaborate treatise ascribed to this last writer, who also contributed to our knowledge of the compounds of zinc, bismuth and arsenic. All the common occurring elements and compounds appear to have received notice by the alchemists; but the writings assigned to the alchemical period are generally so vague and indefinite that it is difficult to determine the true value of the results obtained.

In the succeeding iatrochemical period, the methods of the alchemists were improved and new ones devised. Glauber showed how to prepare hydrochloric acid, spiritus solis, by heating rock-salt with sulphuric acid, the method in common use to-day; and also nitric acid from saltpetre and arsenic trioxide. Libavius obtained sulphuric acid from many substances, e.g. alum, vitriol, sulphur and nitric acid, by distillation. The action of these acids on many metals was also studied; Glauber obtained zinc, stannic, arsenious and cuprous chlorides by dissolving the metals in hydrochloric acid, compounds hitherto obtained by heating the metals with corrosive sublimate and subsequently supposed to contain mercury. The scientific study of salts dates from this period, especial interest being taken in those compounds which possessed a medicinal or technical value. In particular, the salts of potassium, sodium and ammonium were carefully investigated, but sodium and potassium salts were rarely differentiated. The metals of the alkaline earths were somewhat neglected; we find Georg Agricola considering gypsum (calcium sulphate) as a compound of lime, while calcium nitrate and chloride became known at about the beginning of the 17th century. Antimonial, bismuth and arsenical compounds were assiduously studied, a direct consequence of their high medicinal importance; mercurial and silver compounds were investigated for the same reason. The general tendency of this period appears to have taken the form of improving and developing the methods of the alchemists; a few new fields were opened, and apart from a more complete knowledge of the nature of salts, no valuable generalizations were attained.

The discovery of phosphorus by Brand, a Hamburg alchemist, in 1669 excited chemists to an unwonted degree; it was also independently prepared by Robert Boyle and J. Kunckel, Brand having kept his process secret. Towards the middle of the 18th century two new elements were isolated: cobalt by G. Brandt in 1742, and nickel by A. F. Cronstedt in 1750. These discoveries were followed by Daniel Rutherford's isolation of nitrogen in 1772, and by K. Scheele's isolation of chlorine and oxygen in 1774 (J. Priestley discovered oxygen independently at about the same time), and his investigation of molybdenic and tungstic acids in the following year; metallic molybdenum was obtained by P. J. Hjelm in 1783, and tungsten by Don Fausto d'Elhuyar; manganese was isolated by J. G. Gahn in 1774. In 1784 Henry Cavendish thoroughly examined hydrogen, establishing its elementary nature; and he made the far-reaching discovery that water was composed of two volumes of hydrogen to one of oxygen.

The phlogistic theory, which pervaded the chemical doctrine of this period, gave rise to continued study of the products of calcination and combustion; it thus happened that the knowledge of oxides and oxidation products was considerably developed. The synthesis of nitric acid by passing electric sparks through moist air by Cavendish is a famous piece of experimental work, for in the first place it determined the composition of this important substance, and in the second place the minute residue of air which would not combine, although urged for about a century, was subsequently examined by Lord Rayleigh and Sir William Ramsay, who showed that it consisted of a mixture of elementary substances—argon, krypton, neon and xenon (see ARGON).

The 18th century witnessed striking developments in pneumatic chemistry, or the chemistry of gases, which had been begun by van Helmont, Mayow, Hales and Boyle. Gases formerly considered to be identical came to be clearly distinguished, and many new ones were discovered. Atmospheric air, of course, had been carefully investigated by Cavendish, who showed that it consisted of two elementary constituents: nitrogen, which was isolated by Rutherford in 1775, and oxygen, isolated in 1774; and Black established the presence, in minute quantity, of carbon dioxide (van Helmont's gas sylvestre). Of the many workers in this field, Priestley occupies an important position. A masterly device, initiated by him, was to collect gases over mercury instead of water; this enabled him to obtain gases previously only known in solution, such as ammonia, hydrochloric acid, silicon fluoride and sulphur dioxide. Sulphuretted hydrogen and nitric oxide were discovered at about the same time.

Returning to the history of the discovery of the elements and their more important inorganic compounds, we come in 1789 to M. H. Klaproth's discovery of a previously unknown constituent of the mineral pitchblende. He extracted a substance to which he gave the name of an element, naming it uranium (from Urano, heaven); but it was afterwards shown by E. M. Péligot, who prepared the pure metal, that Klaproth's product was really an oxide. This element was investigated at a later date by Sir Henry Roscoe, and more thoroughly and successfully by C. Zimmermann and Alibegoff. Pitchblende attained considerable notoriety towards the end of the 19th century on account of two important discoveries. The first, made by Sir William Ramsay in 1866, was that the mineral evolved a peculiar gas when treated with sulphuric acid; this gas, helium (q.v.), proved to be identical with a constituent of the sun's atmosphere, detected as early as 1868 by Sir Norman Lockyer during a spectroscopic examination of the sun's chromosphere. The second discovery, associated with the Curies, is that of the peculiar properties exhibited by the impure substance, and due to a constituent named radium. The investigation of this substance and its properties (see RADIOACTIVITY) has proceeded so far as to render it probable that the theory of the unalterability
of elements, and also the hitherto accepted explanations of various celestial phenomena—the source of solar energy and the theory, established its power—may require recasting.

In the same year as Klaproth detected uranium, he also isolated zirconia or zirconium oxide from the mineral variously known as zircon, hyacinth, jacinth, and jargon; but he failed to obtain the metal, this being first accomplished some years later by Berzelius, who decomposed the double potassium zirconium fluoride with potassium. In the following year, 1795, Klaproth announced the discovery of a third new element, potassium oxide, its isolation (in a very pure form), as in the case of zirconium, was reserved for Berzelius.

Passing over the discovery of carbon disulphide by W. A. Lampaadius in 1796, of chromium by L. N. Vauquelin in 1797, and Klaproth’s investigation of tellurium in 1798, the next important series of observations was concerned with platinum and the allied metals. Platinum had been described by Antonio de Ulloa in 1748, and subsequently discussed by H. T. Scheffer in 1752. In 1803 W. H. Wollaston discovered palladium, especially interesting for its striking property of absorbing (“occluding”) water vapor, in which it is known by its symbol Pd. In 1808 Davy isolated hydrogen at ordinary temperatures and at 634 volumes at 90°. In the following year he discovered rhodium, and at about the same time Smithson Tennant added two more to the list—iridium and osmium; the former was so named from the changing tints of its oxides (πριξ, rainbow), and the latter from the odour of its oxide (οφρυ, smell). The most recently discovered “platinum metal,” ruthenium, was recognized by C. E. Claus in 1845. The great number and striking character of the compounds of this group of metals have formed the subject of many investigations, and already there is a most voluminous literature. Berzelius was an early worker in this field; he was succeeded by Bunsen, and Deville and Debay, who worked out the separation of rhodium, and at a later date by P. T. Cleve, the first to make a really thorough study of these elements and their compounds.

Of especial note are the curious compounds formed by the union of carbon monoxide with platinous chloride, discovered by Paul Schützenberger and subsequently investigated by F. B. Mylius and by F. F. Förster, and by G. H. Poulter; the phosphoplatinum compounds formed primarily from platinum and phosphorus pentachloride; and also the “ammonio” compounds, formed by the union of ammonia with the chloride, &c., of these metals, which have been studied by many chemists, especially S. M. Jörgensen. Considerable uncertainty existed as to the atomic weights of these metals, the values obtained by Berzelius being doubtful. K. F. O. Seubert redetermined this constant for platinum, osmium, and iridium; E. H. Keiser for palladium, and A. A. Joly for ruthenium.

The beginning of the 19th century witnessed the discovery of certain powerful methods for the analysis of compounds and the isolation of elements. Berzelius’s investigation of the action of the electric current on salts clearly demonstrated the invaluable assistance that electrolysis could render to the isolator of elements; and the adoption of this method by Sir Humphry Davy for the analysis of the hydrates of the metals of the alkalis and alkaline earths, and the results which he thus achieved, led to the discovery of potassium, electrometre, and by P. F. G. de la Rue, the phosphoplatinum compounds formed primarily from platinum and phosphorus pentachloride; and also the “ammonio” compounds, formed by the union of ammonia with the chloride, &c., of these metals, which have been studied by many chemists, especially S. M. Jörgensen. Considerable uncertainty existed as to the atomic weights of these metals, the values obtained by Berzelius being doubtful. K. F. O. Seubert redetermined this constant for platinum, osmium, and iridium; E. H. Keiser for palladium, and A. A. Joly for ruthenium.

The discovery of boron by Gay Lussac and Davy in 1809 led Berzelius to investigate silica (siles). In the following year he announced that silica was the oxide of a hitherto unrecognized element, which he named silicium, considering it to be a metal. This has proved to be erroneous; it is non-metallic in character, and its name was altered to silicon, from analogy with carbon and boron. At the same time Berzelius obtained the element, in an impure condition, by fusing silica with charcoal and iron in a blast furnace; its preparation in a pure condition he first accomplished in 1823, when he invented the method of heating double potassium fluorides with metallic potassium. The success which attended his experiments in the case of silicon led him to apply it to the isolation of other elements. In 1824 he obtained zirconium from potassium zirconium fluoride; the preparation of (impure) titanium quickly followed, and in 1828 he obtained thorium. A similar process, and equally efficacious, was introduced by F. Wöhler in 1827. It consisted in heating metallic chlorides with potassium, and was first applied to aluminium, which was isolated in 1827; in the following year, beryllium chloride was analysed by the same method, beryllium oxide (berylla or glauca) having been known since 1798, when it was detected by L. N. Vauquelin in the gem-stone beryl.

In 1812 B. Courtis isolated the element iodine from “kelp,” the burned ashes of marine plants. The chemical analogy of this substance to chlorine was quickly perceived, especially after its investigation by Davy and Gay Lussac. Cyanogen, a compound which in combination behaved very similarly to chlorine and iodine, was isolated in 1815 by Gay Lussac. This discovery of the first of the then-styled “compound radicals” exerted great influence on the prevailing views of chemical composition. Hydrochloric acid was first investigated at about this time by Davy, Faraday and Gay Lussac, its composition and the elementary nature of chlorine being thereby established.

In 1817 F. Stromehey detected a new metallic element, cadmium, in certain zinc ores; it was rediscovered at subsequent dates by other observers and its chemical resemblance to zinc noticed. In the same year Berzelius discovered selenium in a deposit from sulphuric acid chambers, his masterly investigation including a study of the hydride, oxides and other compounds. Selenic acid was discovered by E. Mitscherlich, who also observed the similarity of the crystallographic characters of selenates and sulphates, which afforded valuable corroboration of his doctrine of isomorphism. More recent and elaborate investigations in this direction by A. E. H. Tuton have confirmed this view.

In 1818 L. J. Thénard discovered hydrogen dioxide, one of the most interesting inorganic compounds known, which has since been carefully investigated by H. E. Schöne, M. Traube, and others. About the same time, J. A. Arfwedson, a pupil of Berzelius, detected a new element, which he named lithium, in various minerals—notably petalite. Although unable to isolate the metal, he recognized its analogy to sodium and potassium; this was confirmed by R. Bunsen and A. Matthiessen in 1825, who obtained the metal by electrolysis and thoroughly examined it and its compounds. Its crimson flame-coloration was observed by C. G. Gmelin in 1818.

The discovery of bromine in 1826 by A. J. Balard completed for many years Berzelius’s group of “halogen” elements; the remaining member, fluorine, notwithstanding many attempts, remains unisolated until 1886, when Henri Maissan obtained it by the electrolysis of potassium fluoride dissolved in hydrofluoric acid. Hydrobromic and hydroiodic acids were investigated by Gay Lussac and Balard, while hydrochloric acid received considerable attention at the hands of Gay Lussac, Thénard and Berzelius. We may, in fact, consider that the descriptive study of the various halogen compounds dates from about this time. Balard discovered chlorine monoxide in 1834, investigating its properties and reactions; and his observations on hypo-hydrachloric acid and hypochlorites led him to conclude that “bleaching-powder” or “chloride of lime” was a compound or mixture in equimolecular proportions of calcium chloride and hypochlorite, with a little calcium hydrate. Gay Lussac investigated chloric acid; Stillman discovered perchloric acid, since more fully studied by G. S. Berzelius and Roscoe; Davy and Stillman investigated chloric oxide, formed by treating potassium chloride with sulphuric acid. Davy also discovered and partially investigated the gas, named by him “euclore,” obtained by heating potassium chloride with hydrochloric acid; this gas has been more recently examined by Patallo. The oxy-acids of iodine were investigated by Davy and H. G. Magnus; periodic acid, discovered by the latter, is characterized by the striking complexity of its salts as pointed out by Kimmins.
In 1830 N. G. Sefström definitely proved the existence of a metallic element vanadium, which had been previously detected (in 1801) in certain lead ores by A. M. del Rio; subsequent elaborate researches by Sir Henry Roscoe showed many inaccuracies in the conclusions of earlier workers (for instance, the substance considered to be the pure element was in reality an oxide) and provided science with an admirable account of this element and its compounds. B. W. Gerland contributed to our knowledge of vanadyl salts and the vanadic acids. Chemically related to vanadium are the two elements tantalum and columbium or niobium. These elements occur in the minerals columbite and tantalite, and their compounds became known in the early part of the 19th century by the labours of C. Hatchett, A. G. Ekeberg, W. H. Wollaston and Berzelius. But the knowledge was very imperfect; neither was it much clarified by H. Rose, who regarded niobium oxide as the element. The subject was revived in 1866 by C. W. Blomstrand and J. C. Marignac, to whom is due the credit of first showing the true chemical relations of these elements. Subsequent researches by Sainte Claire Deville and L. J. Troost, and by A. G. Krüss and L. E. Nilson, and subsequently (1904) by Hall, rendered notable additions to our knowledge of these elements and their compounds. These researches have been mainly employed in the same manner as tungsten, for the production of the filaments employed in incandescent electric lighting.

In 1833 Thomas Graham, following the paths already traced out by E. D. Clarke, Gay Lussac and Stromeyer, published his masterly investigation of the various phosphoric acids and their salts, obtaining results subsequently employed by J. von Liebig in establishing the doctrine of the characterization and basicity of acids. Both phosphoric and phosphorous acids became known, although imperfectly, towards the end of the 18th century; phosphorous acid was first obtained pure by Davy in 1812, while pure phosphoric oxide, the anhydride of phosphoric acid, remained unknown until T. E. Thorpe's investigation of the products of the slow combustion of phosphorus. Of other phosphorus compounds we may here notice Gengembre's discovery of phosphuretted hydrogen (phosphine) in 1783, the analogy of which to ammonia was first pointed out by Davy and supported at a later date by H. Rose; liquid phosphorus was first obtained by Thénard in 1828; and hypophosphoric acid was discovered by Dulong in 1816. Of the halogen compounds of phosphorus, the trichloride was discovered by Gay Lussac and Thénard, while the pentachloride was obtained by Davy. The oxychloride, bromides, and other compounds were subsequently discovered; here we need only notice Moissan's preparation of the trifluoride and Thorpe's discovery of the pentafluoride, a compound of special note, for it volatilizes unchanged, giving a vapour of normal density and so demonstrating the stability of the pentavalent phosphorus compound (the pentachloride and pentabromide dissociate into a molecule of the halogen element and phosphorus trichloride).

In 1840 C. F. Schönbein investigated ozone, a gas of peculiar odour (named from the Gr. σκωμ, to smell) observed in 1795 by Martin van Marum to be formed by the action of a silent electric discharge on the oxygen of the air; he showed it to be an allotropic modification of oxygen, a view subsequently confirmed by Marignac, Andrews and Soret. In 1845 a further contribution to our study of allogenic was made by August Schröter, who investigated the transformations of yellow and red phosphorus, phenomena previously noticed by Berzelius, the inventor of the term “allotropy.” The preparation of crystalline boron in 1856 by Wöhler and Sainte Claire Deville showed that this element also existed in allotropic forms, amorphous boron having been obtained simultaneously and independently in 1809 by Gay Lussac and Davy. Before leaving this phase of inorganic chemistry, we may mention other historical examples of allotropy. Of great importance is the chemical identity of the diamond, graphite and charcoal, a fact demonstrated in part by Lavoisier in 1773, Smithson Tennant in 1796, and by Sir George Steuart-Mackenzie (1780–1843), who showed that equal weights of these three substances yielded the same weight of carbon dioxide on combustion. The allotropy of selenium was first investigated by Berzelius; and more fully in 1851 by J. W. Hittorf, who carefully investigated the effects produced by heat; crystalline selenium possesses a very striking property, viz. when exposed to the action of light its electric conductivity increases. Another element occurring in allotropic forms is sulphur, of which many forms have been described. E. Mitscherlich was an early worker in this field. A modification known as “black sulphur,” soluble in water, was announced by F. L. Knapp in 1848, and a colloidal modification was described by H. Debus. The dynamical equilibrium between rhombic, liquid and monosymmetric sulphur has been worked out by H. W. Bakhuis Roozeboom. The phenomenon of allotropy is not confined to the non-metals, for evidence has been advanced to show that allotropy is far commoner than hitherto supposed. Thus the researches of Carey Lca, E. A. Schneider and others, have proved the existence of “colloidal silver”; similar forms of the metals gold, copper, and of the platinum metals have been described. The allotropy of arsenic and antimony is also worthy of notice, but in the case of the first of these elements and of antimony, the modification is the iodating of that of phosphorus. The term allotropy has also been applied to inorganic compounds, identical in composition, but assuming different crystallographic forms. Mercuric oxide, sulphide and iodide; arsenic trioxide; titanium dioxide and silicon dioxide may be cited as examples.

The joint discovery in 1859 of the powerful method of spectrum analysis (see SPECTROSCOPY) by G. R. Kirchhoff and R. W. Bunsen, and its application to the detection and the characterization of elements when in a state of incandescence, rapidly led to the discovery of many hitherto unknown elements. Within two years of the invention the authors announced the discovery of two metals, rubidium and caesium, closely allied to sodium, potassium and lithium in properties, in the mineral lepidolite and in the Dürrheim mineral water. In 1861 Sir William Crookes detected thallium (named from the Gr. αθλος, a green bud, on account of a brilliant green line in its spectrum) in the selenious mud of the sulphuric acid manufacture; the chemical affinities of this element, on the one hand approximating to the metals of this group, and on the other being very closely related to lead, were well established by C. A. Lamy. Of other metals first detected by the spectroscope mention is to be made of indium, determined by F. Reich and H. T. Richter in 1863, and of gallium, detected in certain zinc blende by Lecoq de Boisbaudran in 1875. The spectroscope has played an all-important part in the characterization of the elements, which, in combination with oxygen, constitute the group of substances collectively named the “rare earths.” The substances occur, in very minute quantity, in a large number of sparingly-distributed and comparatively rare minerals—euxenite, samarskite, cerite, yttrotantalite, &c. Scandinavian specimens of these minerals were examined by J. Gadolin, M. H. Klaproth, and especially by Berzelius; these chemists are to be regarded as the pioneers in this branch of descriptive chemistry. Since their day many chemists have entered the lists, new and powerful methods of research have been devised, and several new elements definitely characterized. Our knowledge on many points, however, is very chaotic; great uncertainty and conflict of evidence circulate around many of the new elements, but have been announced, so much so that P. T. Cleave proposed to divide the “rare earth” metals into two groups, (1) “perfectly characterized”; (2) “not yet thoroughly characterized.” The literature of this subject is very large. The memorial address on J. C. G. de Marignac, a noted worker in this field, delivered by Cleve, a high authority on this subject, before the London Chemical Society (J. C. S. Trans., 1895, p. 468), and various papers in the same journal by Sir William Crookes, Bohuslav Brauner and others should be consulted for details.

In the separation of the constituents of the complex mixture of oxides obtained from the “rare earth” minerals, the methods
CHEMISTRY

IV. ORGANIC CHEMISTRY

While inorganic chemistry was primarily developed through the study of minerals—a connexion still shown by the French appellation chimie minérale—organic chemistry owes its origin to the investigation of substances occurring in the vegetable and animal organisms. The quest of the alchemists for the philosopher's stone, and the almost general adherence of the later chemists to the study of the medicinal characters and preparation of metallic compounds, stultified in some measure the investigation of vegetable and animal products. It is true that by the distillation of many herbs, resins and similar substances, several organic compounds had been prepared, and in a few cases employed as medicines; but the prevailing classification of substances by physical and superficial properties led to the correlation of organic and inorganic compounds, without our realizing the chemical composition. The clarification and spirit of research so clearly emphasized by Robert Boyle in the middle of the 17th century is reflected in the classification of substances expounded by Nicolas Lémery, in 1675, in his Cours de chimie. Taking as a basis the nature of the source of compounds, he framed three classes: "mineral," comprising the metals, minerals, earths and stones; "vegetable," comprising plants, resins, gums, juices, &c.; and "animal," comprising animals, their different parts and excreta. Notwithstanding the inconsistency of his allocation of substances to the different groups (for instance, acetic acid was placed in the vegetable class, while the acetates and the products of their dry distillation, acetic, &c., were placed in the mineral class), this classification came into favour. The phlogistonians endeavoured to introduce chemical notions to support it: Becher, in his Physica subterranea (1669), stated that mineral, vegetable and animal matter contained the same elements, but that more simple combinations prevailed in the mineral kingdom; while Stahl, in his Specimen becherianum (1702), held the "earthy" principle to predominate in the mineral class, and the "aqueous" and "combustible" in the vegetable and animal classes. It thus happened that in the earlier treatises on phlogistic chemistry organic substances were grouped with all combustibles.

The development of organic chemistry from this time until almost the end of the 18th century was almost entirely confined to such compounds as had practical applications, especially in pharmacy and dyeing. A new and energetic spirit was introduced by Scheele; among other discoveries this gifted experimenter isolated and characterized many organic acids, and proved the general occurrence of glycerin (Olsiiss) in all oils and fats. Bergman worked in the same direction; while Rouelle was attracted to the study of animal chemistry. Theoretical speculations were revived by Lavoisier, who, having explained the nature of combustion, turned to the methods. For analysing compounds, concluded that vegetable substances ordinarily contain carbon, hydrogen and oxygen, while animal substances generally contained, in addition to these elements, nitrogen, and sometimes phosphorus and sulphur. Lavoisier, to whom chemistry was primarily the chemistry of oxygen compounds, having developed the radical theory initiated by Guyton de Morveau, formulated the hypothesis that vegetable and animal substances were oxides of radicals composed of carbon and hydrogen; moreover, since simple radicals (the elements) can form more than one oxide, he attributed the same character to his hydrocarbon radicals: he considered, for instance, sugar to be a neutral oxide and oxalic acid a higher oxide of a certain radical, for, when oxidized by nitric acid, sugar yields oxalic acid. At the same time, however, he adhered to the classification of Lémery; and it was only when identical compounds were obtained from both vegetable and animal sources that this subdivision was discarded, and the classes were assimilated in the division of organic chemistry.

At this time there existed a belief, held at a later date by Berzelius, Gmelin and many others, that the formation of organic compounds was conditioned by a so-called vital force; and the difficulty of artificially realizing this action explained the supposed impossibility of synthesizing organic compounds.
This dogma was shaken by Wöhler's synthesis of urea in 1828. But the belief died hard; the synthesis of urea remained isolated for many years, and many explanations were attempted by the vitalists (as, for instance, that urea was halfway between the inorganic and organic kingdoms, or that the carbon, from which it was obtained, retained the essentials of this hypothetical vital force), but only to succumb at a later date to the indubitable fact that the same laws of chemical combination prevail in both the animate and inanimate kingdoms, and that the artificial or laboratory synthesis of any substance, either inorganic or organic, is a question of time, once its constitution is determined.\(^1\)

The exact delimitation of inorganic and organic chemistry engrossed many minds for many years; and on this point there existed considerable divergence of opinion for several decades. In addition to the vitalistic doctrine of the origin of organic compounds, views based on purely chemical considerations were advanced. The atomic theory, and its corollaries—the laws of constant and multiple proportions—had been shown to possess absolute validity so far as well-characterized inorganic compounds were concerned; but it was open to question whether organic compounds obeyed the same laws. Berzelius, in 1813 and 1814, by improved methods of analysis, established that the Daltonian laws of combination held in both the inorganic and organic kingdoms; and he adopted the view of Lavoisier that organic compounds were oxides of compound radicals, and therefore necessarily contained at least three elements—carbon, hydrogen and oxygen. This view was accepted in 1817 by Leopold Gmelin, who, in his Handbuch der Chemie, regarded inorganic compounds as being of binary composition (the simplest being oxides, both acid and basic, which by combination form salts also of binary form), and organic compounds as ternary, i.e. composed of three elements; furthermore, he concluded that inorganic compounds could be synthesized, whereas organic compounds could not. A consequence of this empirical division was that marsh gas, ethylene and cyanogen were regarded as inorganic, and at a later date many other hydrocarbons of undoubtedly organic nature had to be included in the same division.

The binary conception of compounds held by Berzelius received apparent support from the observations of Gay Lussac, in 1815, on the vapour densities of alcohol and ether, which pointed to the conclusion that these substances consisted of one molecule of water and one and two of ethylene respectively; and from Pierre Jean Robiquet and Jean Jacques Colin, showing, in 1816, that ethyl chloride (hydrochloric ether) could be regarded as a compound of ethylene and hydrochloric acid.\(^2\) Compound radicals came to be regarded as the immediate constituents of organic compounds; and, at first, a determination of their empirical composition was supposed to be sufficient to characterize them. To this problem there was added another in about the third decade of the 19th century—namely, to determine the manner in which the atoms composing the radical were combined; this supplementary requisite was due to the discovery of the isomerism of silver fulminate and silver cyanate by Jean Baptiste Doré and Lacroix, and Faraday's discovery of butylene, isomeric with ethylene, in 1825.

The classical investigation of Liebig and Friedrich Wöhler on the radical of benzoic acid ("Über das Radikal der Benzoësäure," Ann. Chem., 1832, p. 249) is to be regarded as a most important contribution to the radical theory, for it was shown that a radical containing the elements carbon, hydrogen and oxygen, which they named benzoil (the termination \(y\) coming from the Gr. \(y\lambda\eta\), matter), formed the basis of benzaldehyde, benzoic acid, benzoyl chloride, benzoyl bromide and benzoyl sulphide, benzamide and benzoic ether. Berzelius immediately appreciated the importance of this discovery, notwithstanding

\(^1\) The reader is specially referred to the articles Allizarin; Indigo; Pyroxylin and Terpenes for illustrations of the manner in which chemists have artificially prepared important animal and vegetable products.

\(^2\) These observations were generalized by J. B. Dumas and Polidore Bouilla (1806-1855) in their "etherin theory" (vide infra).
More explicit opposition to the dualistic theory of Berzelius was hardly possible; this illustrious chemist perceived that the validity of his electrochemical theory was called in question, and therefore he waged a vigorous war upon Dumas and his followers. But he fought in a futile cause; to explain the facts put forward by Dumas he had to invent intricate and involved hypotheses, which, it must be said, did not meet with general acceptance; Liebig seceded from him, and invited Wöhler to endeavour to correct him. Still, till the last Berzelius remained faithful to his original theory; experiment, which he had hitherto held to be the only sure method of research, he discarded, and in its place he substituted pure speculation, which greatly injured the radical theory. At the same time, however, the conception of radicals could not be entirely displaced, for the researches of Liebig and Wöhler, and those made subsequently by Bunsen, demonstrated beyond all doubt the advantages which would accrue from their correct recognition.

A step forward—the fusion of Dumas' type theory and the radical theory—was made by Laurent and Charles Gerhardt. As early as 1842, Gerhardt in his Précis de chimie organique exhibited a marked leaning towards Dumas' theory, and it is without doubt that both Dumas and Laurent exercised considerable influence in this respect. Unwilling to discard the strictly unitarian view of the chemists, Laurent, to substitute the con-plexes of acid residues, put forward a modification of the generalization of Berzelius, he revived the notion of radicals in a new form. According to Gerhardt, the process of substitution consisted of the union of two residues to form a unitary whole; these residues, previously termed "compound radicals," are atomic complexes which remain over from the interaction of two compounds. Thus, he interpreted the interaction of benzene and nitric acid as \( C_6H_5 + HNO_3 = C_6H_4NO_2 + H_2O \), the "residues" of benzene being \( C_6H_4 \) and \( H \), and of nitric acid \( \text{HO} - \text{HNO}_2 \). Similarly he represented the reactions investigated by Liebig and Wöhler on benzyol compounds as double decompositions.

This rejuvenation of the notion of radicals rapidly gained favour; and the complete fusion of the radical theory with the theory of types was not long delayed. In 1849 C. A. Wurtz discovered the amines or substituted amonias, previously predicted by Liebig; A. W. von Hofmann continued the investigation, and established their recognition as amonias in which one or more hydrogen atoms had been replaced by hydrocarbon radicals, thus formulating the "ammonia type." In 1850 A. W. Williamson showed how alcohol and ether were to be regarded as derived from the hydrocarbon radical of the alcohol or hydrogen atoms by the ethyl group; he derived acids and the acid anhydrides from the same type; and from a comparison of many inorganic and the simple organic compounds he concluded that this notion of a "water-type" clarified, in no small measure, the conception of the structure of compounds.

These conclusions were co-ordinated in Gerhardt's "new theory of types." Taking as types hydrogen, hydrochloric acid, water and ammonia, he postulated that all organic compounds were referable to these four forms: the hydrogen type included hydrocarbons, aldehydes and ketones; the hydrochloric acid type, the chlorides, bromides and iodides; the water type, the alcohols, ethers, monobasic acids, acid anhydrides, and the analogous sulphur compounds; and the ammonia type, the amines, acid-amides, and the analogous phosphorus and arsenic compounds. The recognition of the polybasity of acids, which followed from the researches of Thomas Graham and Liebig, had caused Williamson to suggest that dibasic acids could be referred to a double water type, the acid radical replacing an atom of hydrogen in each water molecule; while his discovery of tribasic organic ethers, \( CH(OH)CH_3 \), in 1856 suggested a triple water type. These views were extended by William Odling, and adopted by Gerhardt, but with modifications of Williamson's aspects. A further generalization was effected by August Kekulé, who rejected the hydrochloric acid type as unnecessary, and introduced the methane type and condensed mixed types. Pointing out that condensed types can only be fused with a radical replacing more than one atom of hydrogen, he laid the foundation of the doctrine of valency, a doctrine of incalculable service to the knowledge of the structure of chemical compounds.

At about the same time Hermann Kolbe attempted a re-habilitation, with certain modifications, of the dualistic conception of Berzelius. He rejected the Berzelian tenet as to the unalterability of radicals, and admitted that they exercised a considerable influence upon the compounds with which they were copulated. By his own investigations and those of Sir Edward Frankland it was proved that the radical methyl existed in acetic acid; and by the electrolysis of sodium acetate, Kolbe Clarked that he had isolated this radical; in this, however, he was wrong, for he really obtained ethane, \( C_2H_6 \), and not methyl, \( CH_3 \). From similar investigations of valeric acid he was led to conclude that fatty acids were oxygen compounds of the radicals hydrogen, methyl, ethyl, \&c., combined with the double carbon equivalent \( C_2 \). Thus the radical of acetic acid, acetyl, \(^1\) was \( CH_3CO \). (It will be noticed that Kolbe used the atomic weights \( H=1 \), \( C=6 \), \( O=8 \), \( S=16 \), \&c.; in his formulae, however, were molecular formulae, i.e. the molecular weights were the same as in use to-day.) This connecting link, \( C_2 \), was regarded as essential, while the methyl, ethyl, \&c., was but a sort of appendage; but Kolbe could not clearly conceive the manner of copulation.

The brilliant researches of Frankland on the organo-metallic compounds, and his consequent doctrine of saturation capacity or valency of elements and radicals, relieved Kolbe's views of all obscurity. The doctrine of copulae was discarded, and in 1859 emphasis was given to the view that all organic compounds were derivatives of inorganic by simple substitution processes. He was thus enabled to predict compounds then unknown, e.g. the secondary and tertiary alcohols; and with inestimable perspicacity he proved intimate relations between compounds previously held to be quite distinct. Lactic acid and alamine were shown to be oxy- and amino-proponic acids respectively; glycollic acid and glucycol, oxy- and amino-acetic acids; salicylic and benzoic acids, oxy- and amino-benzoic acids.

Another consequence of the doctrine of valency was that it permitted the graphic representation of the molecule. The "structure theory" (or the mode of linking of the atoms) of carbon compounds, founded by Butlerow, Kekulé and Couper and, at a later date, marvellously enhanced by the doctrine of stereo-isomerism, due to J. H. van't Hoff and Le Bel, occupies such a position in organic chemistry that its value can never be transcended. By its aid the molecule is represented as a collection of atoms connected together by valencies in such a manner that the part played by each atom is represented; isomerism, or the existence of two or more chemically different substances having identical molecular weights, is adequately shown; and, most important of all, once the structure is determined, the synthesis of the compound is but a matter of time.

In this summary the leading factors which have contributed to a correct appreciation of organic compounds have so far been considered historically, but instead of continuing this method it has been thought advisable to present an epitome of present-day conclusions, not chronologically, but as exhibiting the principles and subject-matter of our science.

Classification of Organic Compounds.

An apt definition of organic chemistry is that it is "the study of the hydrocarbons and their derivatives." This description, absolutely comprehensive, serves as a convenient starting-point for a preliminary classification, since a great number of substances, including the most important, are directly referable to hydrocarbons, being formed by replacing one or more hydrogen atoms by other atoms or groups. Two distinct types of hydrocarbons exist: (1) those consisting of an open chain of carbon atoms—named the "aliphatic series" (\( \text{Alkane} \), oil or fat), and (2) those consisting of a closed chain—the "carbocyclic series." The second series can be further divided

\(^1\) This must not be confused with the modern acetyl, \( CH_3CO \), which at that time was known as acetoxy.
into two groups: (1) those exhibiting properties closely analogous to the aliphatic series—the polymethylene (q.v.), and (2) a series exhibiting properties differing in many respects from the aliphatic and polymethylene compounds, and characterized by a peculiar stability which is to be associated with the disposition of certain valencies not saturated by hydrogen—

the "aromatic series." There also exists an extensive class of compounds termed the "heterocyclic series"—these compounds are derived from ring systems containing atoms other than carbon; this class is more generally allied to the aromatic series than to the aliphatic.

We now proceed to discuss the types of aliphatic compounds; then, the characteristic groupings having been established, an epitome of their derivatives will be given. Carboxylic rings will next be treated, benzene and its allies in some detail; and finally the heterocyclic nuclei.

Accepting the doctrine of the tetravalency of carbon (its divinity in such compounds as carbon monoxide, various isocyanides, fulminic acid, &c., and its possible trivality in M. Gomberg's triphenyl-methyl play no part in what follows), it is readily seen that the simplest hydrocarbon has the formula \( CH_4 \), named methane, in which the hydrogen atoms are of equal value, and which may be pictured as placed at the vertices of a tetrahedron, the carbon atom occupying the centre. This tetrahedral configuration is based on the existence of only one hydrogen atom for the carbon atom; the other valencies were considered to lie in a plane square to its corners, and on the existence of two optical isomers of the formula C.A.B.D.E.C, being a carbon atom and A.B.D.E. being different monoatomic valencies or radicals (see Stereo-Isomerism). The equivalence of the four hydrogen atoms of methane rested on indirect evidence, e.g. the existence of only one acetic acid, methyl chloride, and other monosubstitution derivatives—until the experimental proof by L. Henry (Zeit. f. Phys. Chem., 1888, 2, p. 553), who prepared the four nitromethanes, \( CH_3NO_2 \), each in methane being subsequently replaced by the nitro-group.

Henry started with methyl iodide, the formula of which we write in the form \( CH_3I \). This readily gave with silver nitrate a nitromethane in which we may suppose the nitro-group to replace the \( CH_3 \) hydrogen atom, i.e. \( CH_3NO_2 \). The same methyl iodide gave with potassium cyanide, acetonitril, which was hydrolysed to acetic acid; this must be \( CH_3CONH_2 \). Chlorination of this substance gave a monochloroacetic acid; we will assume the chlorine atom to replace the hydrogen atom. This acid with silver nitrate gave a nitroacetic acid, which readily gave the second nitromethane, \( CH_3(NO_2)CH_3 \), identical with the first nitromethane. From the nitroacetic acid obtained above, malonic acid was prepared, and from this a monochloroacetic acid by chlorination of the carbon atom to replace the \( CH_3 \) hydrogen atom. This acid gives with silver nitrate the corresponding nitromalonic acid, which readily yielded the third nitromethane, \( CH_3(NO_2)CH_2NO_2 \), identical also with the first. The fourth nitromethane was obtained from the nitromalonic acid previously mentioned by a repetition of the method by which the third was prepared; this was identical with the other three.

Let us now consider hydrocarbons containing \( x \) atoms of carbon. Three such compounds are possible according to the number of valencies acting directly between the carbon atoms. Thus, if they are connected by one valency, and the remaining valencies saturated by hydrogen, we obtain the compound \( CH_3-CH_3 \), ethane. This compound may be considered as derived from hydrogen, \( CH_4 \), replacing a hydrogen atom by the monoatomic group \( CH_3 \), known as methyl; hence ethane may be named "methylmethylene." If the carbon atoms are connected by two valencies, we obtain a compound \( CH_2=CH_2 \), ethylene. These two compounds are termed unsaturated, whereas ethane is saturated. It is obvious that we have derived three combinations of carbon with hydrogen, characterized by containing a single, double, and triple linkage; and from each of these, by the substitution of a methyl group for a hydrogen atom, compounds of the same nature result. Thus ethane gives \( CH_3-CH_2-CH_3 \), propane; ethylene gives \( H_2C=CH_2 \); propylene; and acetylene gives \( H:C=CH_2 \). By continuing the introduction of methyl groups we obtain three series of homologous hydrocarbons given by the general formulae \( CH_3H_n \), \( CH_3H_n \), and \( CH_3H_{n-3} \), each member differing from the preceding one of the series by \( CH_3 \). It will be noticed that compounds containing two double linkages will have the same general formula as the acetylene series; such compounds are known as the "dienes." Hydrocarbons containing any number of double or triple linkages, as well as both double and triple linkages, are possible, and a considerable number of such compounds have been prepared.

A more complete idea of the notion of a compound radical follows from a consideration of the compound propane. We derived this substance from ethane by introducing a methyl group; hence it is called "methylated" propane. Equally well we may derive it from methane by replacing a hydrogen atom by the monovalent group \( CH_2 \), named ethyl; hence propane may be regarded as "ethylmethane." Further, since methane may be regarded as a combination of a methyl group with a hydrogen atom, it may be named "methyl hydride"; similarly ethane is "ethyl hydride," propane, "propyl hydride," and so on. The importance of such groups as methyl, ethyl, &c., in attempting a nomenclature of organic compounds cannot be overestimated; these compound radicals, frequently termed alkyl radicals, serve a similar purpose to the organic chemist as the elements to the inorganic chemist.

In methane and ethane the hydrogen atoms are of equal value, and no matter which one may be substituted by another element or group the same compound will result. In propane, on the other hand, the hydrogen atoms attached to the terminal carbon atoms differ from those joined to the medial atom; we may therefore expect to obtain different compounds according to the position of the hydrogen atom substituted. By introducing a methyl group we may obtain \( CH_3CH_2-CH_3 \), known as "normal" or \( n \)-butane, substitution occurring at a terminal atom, or \( CH_2=CH(CH_3) \) isobutane, substitution occurring at the medial atom. From \( n \)-butane we may derive, by a similar substitution of methyl groups, the two hydrocarbons: (1) \( CH_3-CH_2CH_2CH_3 \), and (2) \( CH_2=CH(CH_3)CH_3 \); from isobutane we may derive two compounds identical with (1), and a new one (3) \( CH_2=CH(CH_3)CH_3 \). These three hydrocarbons are isomeric, i.e. they possess the same formula, but differ in constitution. We notice that they may be differentiated as follows: (1) is built up solely of methyl and \( CH_2(=CH_2) \) (methylene) groups and the molecule consists of a simple chain; such hydrocarbons are referred to as being normal; (2) has a branch and contains the group \( CH(=CH_2) \) (methylene) in which the free valencies are attached to carbon atoms; such hydrocarbons are termed secondary or iso; (3) is characterized by a carbon atom linked directly to four other carbon atoms; such hydrocarbons are known as tertiary.

Deferring the detailed discussion of cyclic or ringed hydrocarbons, a correlation of the various types or classes of compounds which may be derived from hydrocarbon nuclei will now be given. We shall see that each type, depending upon a specific radical or atom, and the copulation of this character with any hydrocarbon radical (open or cyclic) gives origin to a compound of the same class.

It is convenient first to consider the effect of introducing one, two, or three hydroxyl (OH) groups into the \( CH_3 \), \( >CH_2 \), and \( >CH \) groups, which we have seen to characterize the different types of hydrocarbons. It may be noticed here that cyclic nuclei can only contain the groups \( >CH_2 \) and \( >CH \), the first characterizing the polymethylene and reduced heterocyclic compounds, the second true aromatic compounds.

Substituting one hydroxyl group into each of these residues, we obtain radicals of the type \( -CH_2OH \), \( >CH_2OH \), and \( >COH \); these compounds are known as alcohols (q.v.), and are termed primary, secondary, and tertiary respectively. Polyols (q.v.), having only secondary and tertiary hydroxyls, are characterized by the latter compounds are known as phenols. A second hydroxyl group may be introduced into the residues \( CH_2OH \) and \( COH \); the production of radicals of the form \( -CH(=O)H \), and \( >CH(=O)H \), containing the oxygen atom, may be similarly observed (see Chloral), and it is generally found that when compounds of these types are expected, the elements of water are split off, and the typical groupings are reduced to \( -CH=O \) or \( >C =O \). Compounds containing the group \( -CH=O \) are known as aldehydes (q.v.), while the group \( >C =O \) (sometimes termed the carbonyl or keto group) characterizes the ketones (q.v.). A third hydroxyl group may be
introduced into the $-\text{CH}_2\text{O}$ residue with the formation of the radical $-\text{C(OH)}_2\text{O}$: this is known as the carboxyl group, and characterizes the organic acids.

Sulphur analogues of these oxygen compounds are known. Thus the RS(O)R (named disulphides) contain the group $R\text{S-S}R$, and the elimination of the elements of sulphur-heterocyclic between two molecules of a thio-alcohol results in the formation of a thio-ether or sulphide, R$S\text{R}$. Oxidation of thio-ethers results in the formation of thio-sulphoxides, R$S\text{O}2$, and sulphides, R$S\text{S}2$; oxidation of mercaptides yields thio-acids, R$\text{SH}$, and of sodium mercaptides sulphonic acids, R$\text{SO}_2\text{OH}$. We may also notice that thio-ethers combine with alkali iodides to form sulphine or sulphonium compounds, R$i$; thi-alddehydes, thioketones and thi-acids also exist.

We proceed to consider various simple derivatives of the alcohols, which we may here regard as hydroxyl hydrocarbons, R$\text{OH}$, where R is an alkyl radical, either aliphatic or cyclic in nature.

Of these, undoubtedly the simplest are the ethers (q.v.), formed by the elimination of the elements of water between two molecules of the same alcohol, "simple ethers," or of different alcohols, "mixed ethers." These compounds may be regarded as oxides in just the same way as the alkyl haloids; exactly comparable in structure CH$\text{N}2$ is benzene. Thus, the ketone group and the aldehyde group, as a ketonic nitro-compounds of the type R-CBr$\text{Br}$; nitric acid forms nitrates, R$\text{O}$-NO$2$; nitric acid, nitrates, R$\text{O}$-NO$2$; sulphuric acid gives sulphonic acids, R$\text{SO}_2\text{ON}$, and of various bases, R$\text{ON}$; acids also condense with alcohol to form similar compounds:

- the fats, waxes, and essential oils are naturally occurring substances of this class.

An important class of compounds, termed amines (q.v.), results from the condensation of alcohols with ammonia, water being eliminated between the alcoholic hydroxyl group and a hydrogen atom of the ammonia. Three types of amines are possible and have been prepared: primary, R$\text{NH}_2$; secondary, R$\text{NH}_2$; tertiary, R$i$: R$\text{NH}_2$; the oximes, R$i$: R$\text{N}=\text{O}$; are closely related to the tertiary amines, which also unite with a molecule of alkyl iodide to form salts of quaternary ammonium bases, e.g. R$i$: R$\text{N}2$. It is worthy of note that phosphorous and arsenic bases analogous to the amines are known (see PHOSPHURS and ARSENIC). From the primary amines are derived the diazo compounds (q.v.) and azo compounds (q.v.); closely related are the hydrazines (q.v.). Secondary amines yield nitroso-compounds, R$\text{N}=\text{O}$, which form nitroso-compounds of the type R$\text{NO}$; with nitrous acid, R$i$: R$\text{N}=\text{O}$; with hydroxylamine, R$i$: R$\text{N}=\text{O}$; and with peroxides, R$i$: R$\text{N}=\text{O}$; with hydrogen peroxide. By the action of hydroxylamine or phenylhydrazine on aldehydes or ketones, condensation occurs between the hydroxyl oxygen of the aldehyde or ketone and the amino group of the hydroxylamine or hydrazine. Thus, the aldohydrazine, aldehydehydrazine, ketohydrazine, and ketones, ketoximes, R$i$: R$\text{N}2$: OH (see OXIMES), while phenylhydrazine gives phenyldrazones, R$i$: R$\text{N}=\text{C}=\text{NH}_2$ (see HYDRAZONES). Oxaldehydes and oxo-tetronic acids (viz. compounds containing an oxo-group, e.g. aldehydes, ketones, and aldo-compounds) both condensation and oxidation when treated with phenyldrazine, forming compounds known as osozones; these are of great importance in characterizing the sugars (q.v.).

The carboxyl group constitutes another convenient starting-point for the orientation of many types of organic compounds. This group may be considered as resulting from the fusion of a carboxyl (-CO$\text{O}$) with a hydroxyl (HO$\text{-}$) group; and we may expect to meet with compounds bearing structural resemblances to the derivatives of alcohols and aldehydes (or ketones). Considering derivatives primarily concerned with transformations of the hydroxyl group, we may regard our typical acid as a form of CH$\text{O}$: CH$\text{O}$: CH$\text{O}$: CH$\text{O}$, generally according to the name of the hydrocarbon containing the same number of carbon atoms) and a hydroxyl group. By replacing the hydroxyl group by a halogen, acid-haloids result; by the elimination of an acid, other hydroxyl derivatives are obtained, such as ethers, acids, esters, etc., which may be oxidized to acid-peroxides; by replacing the hydroxyl group by the group -SH, thio-acids; by replacing it by the amino group, acid-amides (q.v.); by replacing it by the group -NH$\text{2}$, amino-compounds. The structural relations of these compounds are here shown:

$$\text{R-CO-OH; R-CO-O; R-CO-SH; (R-CO)$_2$O; R-CO-SH; acid; acid-chloride; acid-anhydride; thio-acid; R-CO-NH; R-CO-NH-; acid-amide; acid-hydrazide.}$$

It is necessary clearly to distinguish such compounds as the amino- (or amido-) acids and acid-amides; in the first case the amino group is substituted in the hydrocarbon residue, in the second it is substituted in the carboxyl group.

By transformations of the carbonyl group, and at the same time of the hydroxyl group, many interesting types of nitrogen compounds may be correlated.

Thus from the acid-amides, which we have seen to be closely related to the hydroxyl, we may obtain by the action of sodium and other bases, the amides, R-C(NH$_2$): NOH, and ammonia, R-C(NH$_2$): NH$_2$. The carboxyl oxygen may also be replaced by the oxide group, NO$_2$; thus the acids yield the hydroxamic acids, R-C(OH): NOH, and the acid-amides the amidoximes, R-C(NH$_2$): NOH. Closely related to the amidoximes are the nitric acids, R-C(NO$_2$): NOH.

Cyclic Hydrocarbons and Nuclei.

Having passed in rapid review the various types of compounds derived by substituting for hydrogen various atoms or groups of atoms in hydrocarbons (the separate articles on specific compounds should be consulted for more detailed accounts), we now proceed to consider the closed chain compounds. Here we meet with a great diversity of types: oxygen, nitrogen, sulphur and other elements may, in addition to carbon, combine together in a great number of arrangements to form cyclic nuclei, which exhibit characters closely resembling open-chain compounds in so far as they yield substitution derivatives, and behave as compound radicals. In classifying closed chain compounds, the first step consists in dividing them into: (1) carbocyclic, in which the ring is composed solely of carbon atoms—these are also known as homocyclic or isocyclic on account of the identity of the members of the ring— and (2) heterocyclic, in which different elements go to make up the ring. Two primary divisions of carbocyclic compounds may be conveniently made: (1) those in which the carbon atoms are completely saturated—these are known by the generic term polyethylene, their general formula being (CH$_2$)$_n$; it will be noticed that they are isomeric with ethylene and its homologues; they differ, however, from this series in not containing a double linkage, but have a ringed structure, and (2) those containing fewer hydrogen atoms than suffice to saturate the carbon valences—these are known as the aromatic compounds proper, or as benzene compounds, from the predominant part which benzene plays in their constitution.

It was long supposed that the simplest ring obtainable contained six carbon atoms, and the discovery of trimethylene in 1882 by August Freund by the action of sodium on trimethylene bromide, Br(CH$_2$)$_3$Br, came somewhat as a surprise, especially in view of its behaviour with bromine and hydrogen bromide. In comparison with the isomeric propylene, CH$_3$:CH:CH, it is remarkably inert, being only very slowly attacked by bromine, which readily combines with propylene. But on the other hand, it is readily converted by hydrobromic acid into normal propyl bromide, CH$_3$:CH$_2$:CH$_2$:Br. The separation of carbon atoms united by single affinities in this manner at the time the observation was made was altogether without precedent. A similar behaviour has since been noticed in other trimethylene derivatives, but the fact that bromine, which usually acts so much more powerfully than hydrobromic acid on unsaturated compounds, should be so slow in effecting the hydrobromic acid acts readily is one still needing a satisfactory explanation. A great impetus was given to the study of polyethylene derivatives by the important and unexpected observation made by W. H. Perkin, jun., in 1883, that ethylene and trimethylene bromides are capable of acting in such a way on sodium acetooxyester as to form tri- and tetra-methylene rings. Perkin has himself contributed largely to our knowledge of such compounds; penta- and hexa-methylene derivatives have also received considerable attention (see POLYETHYLENES).

A. von Baeyer has sought to explain the variations in stability manifest in the various polyethylene rings by a purely mechanical hypothesis, the "strain" or Spannungs theory (Br., 1885, p. 2777). Assuming the four valencies of the carbon atom to be directed from the centre of a regular tetrahedron towards its four corners, the angle at which they meet is 109° 28'. Baeyer supposes that in the formation of carbon
"rings" the valencies become deflected from their positions, and that the tension thus introduced may be deduced from a comparison of this angle with the angles at which the strained valencies would meet. He regards the amount of deflection as a measure of the stability of the "ring." The readiness with which ethylene is acted on in comparison with other types of hydrocarbon, for example, is in harmony, he considers, with the circumstance that the greatest distortion must be involved in its formation, as if deflected into parallelism each valency will be drawn out of its position through $^{180^o}$ $28'$. The values in other cases are calculable from the formula $^{4}(108^o 28' - a)$, where $a$ is the internal angle of the regular polygon contained by sides equal in number to the number of the carbon atoms composing the ring. These values are:—

- Trimethylene. $^{4}(108^o 28' - 60' = 24^o 44')$
- Tetramethylene. $^{4}(108^o 28' - 56' = 5^o 44')$
- Pentamethylene. $^{4}(108^o 28' - 58' = 5^o 16')$
- Hexamethylene. $^{4}(108^o 28' - 108') = 0^o 44'$

The general behaviour of the several types of hydrocarbons is certainly in accordance with this conception, and it is a remarkable fact that when benzene is reduced with hydriodic acid, it is converted into a mixture of hexamethylene and methylpentamethylene (cf. W. Markownikow, Ann., 1898, 302, p. 1); and many other cases of the conversion of six-carbon rings into five-carbon rings have been recorded (see below, Decompositions of the Benzene Ring). Similar considerations will apply to rings containing other elements besides carbon. As an illustration it may be pointed out that in the case of the two known types of lactones—the $\gamma$-lactones, which contain four carbon atoms and one oxygen atom in the ring, are more readily formed and more stable (less readily hydrolysed) than the $\delta$-lactones, which contain one oxygen and five carbon atoms in the ring. That the number of atoms which can be associated in a ring by single affinities is limited there can be no doubt, but there is not yet sufficient evidence to show where the limit must be placed. Baeyer has suggested that his hypothesis may also be applied to explain the instability of acetylene and its derivatives, and the still greater instability of the polycyclic compounds.

**Benzene.**

The ringed structure of benzene, $C_6H_6$, was first suggested in 1865 by August Kekulé, who represented the molecule by six CH groups placed at the six angles of a regular hexagon, the sides of which denote the carbon atoms, and the vertices the valencies of each carbon atom being represented as separated along alternate sides. This formula, notwithstanding many attempts at both disproving and modifying it, has well stood the test of time; the subject has been the basis of constant discussion, many variations have been proposed, but the original conception of Kekulé remains quite as convenient as any of the newer forms, especially when considering the syntheses and decompositions of the benzene complex. It will be seen, however, that the absolute disposition of the fourth valency may be ignored in a great many cases, and consequently the complex may be adequately represented as a hexagon. This symbol is in general use; it is assumed that at each corner there is a CH group which, however, is not always written in; if a hydrogen atom be substituted by another group, then this group is attached to the corner previously occupied by the displaced hydrogen. The following diagrams illustrate these statements:

From the benzene nucleus we can derive other aromatic nuclei, graphically represented by fusing two or more hexagons along common sides. By fusing two nuclei we obtain the formula of napthale, $C_{10}H_{10}$; by fusing three, the hydrocarbons anthracene and phenanthrene, $C_{18}H_{12}$, by fusing four, chrysene, $C_{24}H_{18}$, and possibly pyrene, $C_{24}H_{16}$. By fusing five, picene, $C_{30}H_{20}$, and it must be here understood that each member of these condensed nuclei need not necessarily be identical in structure; thus the central nuclei in anthracene and phenanthrene differ considerably from the terminal nuclei (see below, Condensed Nuclei). Other hydrocarbon nuclei generally classed as aromatic in character result from the union of two or more benzene nuclei joined by one or two valencies with polyethylene or oxidized polyethylene rings; instances of such nuclei are indene, hydridene, fluorene, and fluoranthene. From these nuclei an immense number of derivatives may be obtained, the hydrogen atoms may be substituted by any of the radicals discussed in the preceding section on the classification of organic compounds.

We now proceed to consider the properties, decompositions, constitution and modification of the benzene complex. It has already been stated that benzene derivatives may be regarded as formed by the replacement of hydrogen atoms by other elements or radicals in exactly the same manner as in the aliphatic series. Important differences, however, are immediately met with when we consider the methods by which derivatives are obtained. For example, nitric acid and sulphuric acid readily react with benzene and its homologues with the production of nitro derivatives and sulphonic acids, while in the aliphatic series these acids exert no substituting action (in the case of the olefines, the latter acid forms an addition product); another distinction is that the benzene complex is more stable towards oxidizing agents. This and other facts connected with the stability of benzenoid compounds are clearly shown when we consider mixed aromatic-aliphatic hydrocarbons, i.e. compounds derived by substituting aliphatic radicals in the benzene nucleus; such a compound is methylbenzene or toluene, $C_7H_8$. This compound is readily oxidized to benzoic acid, $C_7H_6COOH$, the aromatic residue being unattacked; nitric and sulphuric acids produce nitro-toluenes, $C_7H_5CH_2NO_2$, and tolune sulphonic acids, $C_7H_5CH_2SO_3H$; chlorination may result in the formation of derivatives substituted either in the aromatic nucleus or in the side chain; the former substitution occurs most readily, chlor-toluenes, $C_7H_5CH_2Cl$, being formed, while the latter, which involves an elevation in temperature or other auxiliary, yields benzyl chloride, $C_7H_5CH_2Cl$, and benzal chloride, $C_7H_5CHCl$. In general, the aromatic residues in such mixed compounds retain the characters of their class, while the aromatic residues retain the properties of benzene.

Further differences become apparent when various typical compounds are compared. The introduction of hydroxyl groups into the benzene nucleus gives rise to compounds generally named phenols, which, although resembling the aliphatic alcohols in their origin, differ from these substances in their increased chemical activity and acid nature. The phenols more closely resemble the tertiary alcohols, since the hydroxyl group is linked to a carbon atom which is united to other carbon atoms by its remaining three valencies; hence on oxidation they cannot yield the corresponding aldehydes, ketones or acids (see below, Decompositions of the Benzene Ring). The amines also exhibit striking differences: in the aliphatic series these compounds may be directly formed from the alkyl haloids and ammonia, but in the benzene series this reaction is quite impossible unless the haloid atom be weakened by the presence of other substituents, e.g. nitro groups. Moreover, while methylamine, dimethylamine, and trimethylamine increase in basicity corresponding to the introduction of successive methyl groups, phenylamine or aniline, diphenylamine, and triphenylamine are in decreasing order of basicity, the salts of diphenylamine being decomposed by water. Mixed aromatic-aliphatic amines, both secondary and tertiary, are also more strongly basic than the pure aromatic amines, and less basic than the true aliphatic compounds; e.g. aniline, $C_6H_5NH_2$, monomethyl aniline, $C_6H_5NH_2H$, and dimethyl aniline, $C_6H_5N(CH_3)_2$, in increasing order of basicity. These observations may be summarized by saying that the benzene nucleus is more negative in character than the aliphatic residues.

**Isomerism of Benzene Derivatives.**—Although Kekulé founded his theory of benzene in 1865 on the assumptions that the six hydrogen atoms in benzene are equivalent and that the molecule is symmetrical, i.e. that two pairs of hydrogen atoms are symmetrically situated with reference to any specified hydrogen atom, the absolute demonstration of the validity of
these assumptions was first given by A. Ladenburg in 1874
(see Ber., 1874, 7, p. 1684; 1875, 8, p. 1666; "Theorie der
aromatischen Verbindungen," 1876). These results may be
graphically represented as follows: numbering the hydrogen
datoms in cyclic order from 1 to 6, then the first thesis demands
that whichever atom is substituted the same compound
atoms, while the second thesis, which is assumed by the
substitution derivatives 1.2 and 1.6, and also 1.3 and 1.5 are
identical. Therefore three di-derivatives are possible, viz.
1.2 or 1.6, named ortho- (o), 1.3 or 1.5, named meta- (m), and
1.4, named para-compounds (p). In the same way it may be
shown that three tri-substitution, three tetra-substitution, one
penta-substitution, and one hexa-substitution derivative are
possible. Of the tri-substitution derivatives, 1.2.3-compounds
are known as "adjacent" or "vicinal" (v), the 1.2.4 as "asym-
metrical" (a), the 1.3.5 as "symmetrical" (s); of the tetra-
substitution derivatives, 1.2.3.4-compounds are known as
"adjacent," 1.2.3.5 as "asymmetrical," and 1.2.4.5 as "sym-
metrical."

Here we have assumed the substitution groups to be alike;
when they are unlike, a greater number of isomers is possible.
Thus in the tri-substitution derivatives six isomers, and no
more, are possible when two of the substituents are alike; for
instance, six diamino benzoic acids, 

\[ \text{C}_6\text{H}_4(\text{NH}_2)_2\text{COOH}, \]

are known; when all are unlike seven isomers are possible; thus,
seven oxytoxylic acids, 

\[ \text{C}_6\text{H}_5\text{CHO}-\text{OH}, \]

are known. In the case of tetra-substituted compounds, thirty
isomers are possible when all the groups are different.

The preceding considerations render it comparatively easy to
follow the reasoning on which the experimental verification of
the above statements is based. The proof is divided into two
parts: (1) that four hydrogen atoms are equal, and (2) that two pairs of hydrogen atoms are symmetrical

**Equivalence of four hydrogen atoms.**

In the first thesis, phenol or oxybenzene, 

\[ \text{C}_6\text{H}_5\text{OH}, \]

in which we shall assume the hydroxyl group to occupy position 1, is converted into bromobenzene, which is then converted into benzoic acid, 

\[ \text{C}_6\text{H}_5\text{COOH}, \]

and the other known benzoic acids (ortho- and para-)

\[ \text{C}_6\text{H}_4\text{COOH}, \]

may be prepared; and the two other known benzoic acids (ortho- and para-)

\[ \text{C}_6\text{H}_4\text{COOH}, \]

are converted into benzoic acid. These three acids yield
on heating phenol, identical with the substance started with, and
this is identical with the starting substance itself. However, the hydroxyl groups occupy one of the positions other than 1, it follows that four hydrogen atoms are equal in value.

R. Hülshoff and A. Petermann (Ann., 1869, 149, p. 129) provided the proof of the equivalence of the atoms 2 and 6 with respect to 1. From meta-bromobenzonic acid twonitrobrombenzoic acids are obtained on direct nitration; elimination of the bromine atom and the reduction of the nitro to an amino group in these two acids results in the formation of the same

ortho-amino-acid. Hence the positions occupied by the

nitro groups in the two different nitrobrombenzoic acids must be symmetrical with respect to the carboxyl group. In 1879, Hülshoff (Ann., 1879, 138, p. 129) showed that the symmetry of the second pair is also established in 1878 by E. Wroblewsky (Ann., 192, p. 196).

**Orientation of Substituent Groups.**—The determination of the relative positions of the substituents in a benzene derivative constitutes an important factor in the general investigation of such compounds. Confining our attention, for the present, to di-substitution products we see that there are three distinct series of compounds to be considered. Generally if any group
be replaced by another group, then the second group enters the
nucleus in the position occupied by the displaced group; this
means that if we can definitely orientate three di-derivatives of benzene, then any other compound, which can be obtained
from or converted into one of our typical derivatives, may be
definitely orientated. Intermolecular transformations—migrations of substitution groups from one carbon atom to another—are of fairly common occurrence among oxygen compounds at elevated temperatures. Thus potassium ortho-xylenoate is
converted into the salt of para-xylenoate at 220°; the three bromophenols, and also the bromobenzensulphonic acids,
yield m-dioxymethylene or resorcin when fused with potash. It
is necessary, therefore, to avoid reactions involving such inter-
molecular migrations when determining the orientation of
aromatic compounds.

A scheme of such typical compounds are the benzene dicarboxylic acids (phthalic acids), 

\[ \text{C}_8\text{H}_4(\text{COOH})_2, \]

C. Graebe (Ann., 1869, 149, 223) proved this by the formation from naphthalene on oxidation; the meta-compound or isophthalic acid is orientated by its production from mesitylene, shown by A. Ladenburg (Ann., 1875, 179, p. 163) to be symmetrical with the para-derivatives, and the ortho acid, the remaining isomer, must therefore be the para-compound.

P. Griess (Ber., 1872, 5, p. 192; 1874, 7, p. 1223) orientated the three dianisobenzene or phenylene diamines by considering their reduction products. Further research in this direction was made by D. E. Noetling (Ber., 1885, 14, p. 1657), who investigated the nitro,
amino- and oxy-xylene in their relations to the three xylens or dimethyl benzences.

The orientation of higher substitution derivatives is determined by considering the di- and tri-substitution compounds into which they can be transformed.

**Substitution of the Benzene Ring.**—As a general rule, homologues and mono-derivatives of benzene react more readily with substituting agents than the parent hydrocarbon; for example, phenol is converted into trimesobenzene by the action of bromine water, and into the nitrophenols by dilute nitric acid; similar activity characterizes aniline. Not only does the substituent group modify the readiness with which the derivative is attacked, but also the nature of the product. Starting with a mono-
derivative, we have seen that a substituent group may enter in either of three positions to form an ortho-, meta-, or para-
compound. Experience has shown that such mono-derivatives as nitro compounds, sulphonic acids, carboxylic acids, aldehydes, and ketones yield as a general rule chiefly the meta-compounds, and this is independent of the nature of the group introduced; on the other hand, benzaldehyde, amino-, homologous-, and hydroxybenzenes yield principally a mixture of the ortho- and para-compounds. These facts are embodied in the "Rule of Crum Brown and J. Gibson" ("Journ. Chem. Soc.
61, p. 367): If the hydrogen compound of the substituent already in the benzene nucleus can be directly oxidized to the corresponding hydroxyl compound, then meta-derivatives predominate on further substitution, if not, then ortho- and para-
derivatives. By further substitution of ortho- and para-
derivatives, in general the same tri-derivative [1.2.4] is formed
(Ann., 1878, 192, p. 219); meta-compounds yield [1.3.4] and
[1.2.3] tri-derivatives, except in such cases as when both sub-
stitution groups are strong acids, e.g. m-dinitrobenzene, then
[1.3.5]-derivatives are obtained.

**Syntheses of the Benzene Ring.**—The characteristic distinctions
;

CHEMISTRY

54
which

exist

between aliphatic and benzenoid compounds make

the transformations of one class

into

the

other

especially

interesting.

In the first place we may notice a tendency of several aliphatic
compounds, e.g. methane, tetrachlormethane, &c, to yield aromatic
compounds when subjected to a high temperature, the so-called
pyrogenetic reactions (from Greek wvp, fire, and yew&.<*>, I produce)
the predominance of benzenoid, and related compounds naphtha-

—

—

lene, anthracene, phenanthrene, &c.
in coal-tar is probably to be
associated with similar pyrocondensations. Long-continued treatment with halogens may, in some cases, result in the formation of
aromatic compounds; thus perchlorbenzene, CoCIs, frequently
appears as a product of exhaustive chlorination, while hexyl iodide,
CbHijI, yields perchlor- and perbrom-benzene quite readily.
The trimolecular polymerization of numerous acetylene compounds substances containing two trebly linked carbon atoms,
— C:C — to form derivatives of benzene is of considerable interest.
M. P. E. Berthelot first accomplished the synthesis of benzene in
1870 by leading acetylene, HC CH, through tubes heated to dull
redness; at higher temperatures the action becomes reversible,
the benzene yielding diphenyl, diphenylbenzene, and acetylene.
The condensation of acetylene to benzene is also possible at ordinary
temperatures by leading the gas over pyrophoric iron, nickel,
cobalt, or spongy platinum (P. Sabatier and J. B. Senderens).
The homologues of acetylene condense more readily; thus allylene,

—

,

•

CH

OCH

yield trimethyl- and
OCH3, and crotonylene, CH3-CI
3
hexamethyl-benzene under the influence of sulphuric acid. Toluene
or mono-methylbenzene results from the pyrocondensation of a
mixture of acetylene and allylene.
Substituted acetylenes also
exhibit this form of condensation; for instance, bromacetylene,
BrC CH, is readily converted into tribrombenzene, while propiolic
acid, HC C-COOH, under the influence of sunlight, gives benzene
•

,

:

tricarboxylic acid.
larger and more important series of condensations may be
grouped together as resulting from the elimination of the elements

in the presence of sulphuric acid, to s-tri-

methylbenzene or mesitylene, C6H 3 (CH 3 )3, first observed in 1837 by
R. Kane; methylethyl ketone and methyl- n-propyl ketone suffer
similar condensations to j-triethylbenzene and s-tri-n-propylbenzene
respectively.
Somewhat similar condensations are : of geranial or
citral, (CH 3 ) 2 CH-CHrCH:CH-C(CH 3 ):CH-CHO, to />-isopropylmethylbenzene or cymene; of the condensation product of methylethylacrolein and acetone,
3 -CH 2 -CH:C(CH 3 )-CH:CH-CO-CH3,
to [1. 3. 4]-trimethylbenzene or pseudocumene ; and of the condensation product of two molecules of isovaleryl aldehyde with one
of acetone, C 3 7 -CH 2 -CH:C(C3H T )-CH:CH-CO-CH 3 to (i)-methyl2-4-di-isopropyl benzene.
An analogous synthesis is that of di-

CH

H

,

hydro-m-xylenefrommethylheptenone,(CH 3 )2C:CH-(CH 2 ) 2 -CO-CHs.
Certain o-diketones condense to form benzenoid quinones, two
molecules of the diketone taking part in the reaction; thus diacetyl,
yields £-xyloquinone, CeH 2 (CH 3 ) 2 2 {Ber., 1888,
3 -CO-CO-CH 3
21, p. 141 1), and acetylpropionyl, CHs'C0-CO-C 2 ri 6 yields duroquinone, or tetramethylquinone, C 6 (CH 3 )402, Oxymethylene compounds, characterized by the grouping >C:CH(OH), also give
benzene derivatives by hydrolytic condensation between three
or formyl acetone,
molecules; thus oxymethylene acetone,
CHrCO-CH :CH(OH), formed by acting on formic ester with acetone
in the presence of sodium ethylate, readily yields [i.3.5]-triacetylbenzene, C6H 3 (CO-CH 3 ) 3 ; oxymethylene acetic ester or formyl
acetic ester or /3-oxyacrylic ester, (HO)CH :CH-C0 2 C 2 H5, formed by
condensing acetic ester with formic ester, and also its dimolecular
condensation product, coumalic acid, readily yields esters of [1.3.5]benzene tricarboxylic acid or trimesic acid (see Ber., 1887, 20,

CH

,

,

p. 2930).
In 1890, 0. Doebner (Ber. 23, p. 2377) investigated the condensation
of pyroracemic acid,
3 -CO-COOH, with various aliphatic aldehydes, and obtained from two molecules of the acid and one of the
aldehyde in the presence of baryta water alkylic isophthalic acids:
with acetaldehyde [l.3.5]-methylisophthalic acid or uvitic acid,

C 6 3 -CH 3 -(COOH) 2) was obtained, with propionic aldehyde [1.3.5]ethylisophthalic acid, and with butyric aldehyde the corresponding
propylisophthalic acid.
may here mention the synthesis of
oxyuvitic ester (5-methyl-4-oxy-i-3-benzene dicarboxylic ester) by
the condensation of two molecules of sodium acetoacetic ester
with one of chloroform (Ann., 1883, 222, p. 249). Of other
syntheses of true benzene derivatives, mention may be made of
the formation of orcinol or [3 -5]-dioxy toluene from dehydracetic
acid; and the formation of esters of oxytoluic acid (5-methyl3-oxy-benzoic acid), C 6 3 -CH 3 -OH-COOH,when acetoneoxalic ester,
1889,'
3 -CO-CH 2 -CO-CO-C0 2 C 2 H5, is boiled with baryta (Ber.,
Of interest also are H. B. Hill and J. Torray's observa22, p. 3271).
tions on nitromalonic aldehyde,
2 'CH(CHO) 2 formed by acting on
mucobromic acid, probably CHO-CBr:CBr:COOH, with alkaline
nitrites; this substance condenses with acetone to give £-nitrophenol,

By

passing carbon monoxide over heated potassium

J.

von Liebig

[ORGANIC

discovered, in 1834, an interesting aromatic compound, potassium
carbon monoxide or potassium hexaoxybenzene, the nature of
which was satisfactorily cleared up by R. Nietzki and T. Benckiser
(Ber. 18, p. 499) in 1885, who showed that it yielded hexaoxybenzene, C 6 (Ofi) 6 when acted upon with dilute hydrochloric acid;
further investigation of this compound brought to light a considerable number of highly interesting derivatives (see Quinones).
Another hexa-substituted benzene compound capable of direct
synthesis is mellitic acid or benzene carboxylic acid, C 6 (COOH) 6
This substance, first obtained from the mineral honeystone, aluminium mellitate, by M. H. Klaproth in 1799, is obtained when pure
carbon (graphite or charcoal) is oxidized by alkaline permanganate,
or when carbon forms the positive pole in an electrolytic cell (Ber.,
1883, 16, p. 1209).
The composition of this substance was determined by A. von Baeyer in 1870, who obtained benzene on distilling
the calcium salt with lime.
Hitherto we have generally restricted ourselves to syntheses
which result in the production of a true benzene ring; but there
are many reactions by which reduced benzene rings are synthesized,
and from the compounds so obtained true benzenoid compounds
may be prepared. Of such syntheses we may notice: the condensation of sodium malonic ester to phloroglucin tricarboxylic
ester, a substance which gives phloroglucin or trioxybenzene when
fused with alkalis, and behaves both as a triketohexamethylene
tricarboxylic ester and as a trioxybenzene tricarboxylic ester; the
condensation of succinic ester, (CH 2 -C0 2 C 2 H 5 ) 2 under the influence
of sodium to succinosuccinic ester, a diketohexamethylene dicarboxylic ester, which readily yields dioxyterephthalic acid and
hydroquinone (F. Herrmann, Ann., 1882, 211, p. 306; also see below,
Configuration of the Benzene Complex) the condensation of acetone
dicarboxylic ester with malonic ester to form triketohexamethylene

dicarboxylic ester (E. Rimini, Gazz. Chem., 1896, 26, (2), p. 374);
the condensation of acetone-di-propionic acid under the influence
of boiling water to a diketohexamethylene propionic acid (von
Pechmann and Sidgwick, Ber., 1904, 37, p. 3816). Many diketo
compounds suffer condensation between two molecules to form
hydrobenzene
derivatives;
thus
o,y-di-acetoglutaric

Decompositions of the Benzene Ring. We have previously
alluded to the relative stability of the benzene complex; consequently reactions which lead to its disruption are all the more
interesting, and have engaged the attention of many chemists.
If we accept Kekule's formula for the benzene nucleus, then we
may expect the double linkages to be opened up partially, either
by oxidation or reduction, with the formation of di-, tetra-, or
hexa-hydro derivatives, or entirely, with the production of open
chain compounds. Generally rupture occurs at more than one
and rarely are the six carbon atoms of the complex
point;
regained as an open chain. Certain compounds withstand ring
decomposition much more strongly than others; for instance,
benzene and its homologues, carboxylic acids, and nitro compounds are much more stable towards oxidizing agents than
amino- and oxy-benzenes, aminophenols, quinones, and oxycarboxylic acids.
Strong oxidation breaks the benzene complex into such compounds
as carbon dioxide, oxalic acid, formic acid, &c. such decompositions
are of little interest.
More important are Kekule's „, .
observations that nitrous acid oxidizes pyrocatechol or
x"iSatl° a
[i.2]-dioxybenzene, and protocatechuic acid or [3.4]dioxybenzoic acid to dioxytartaric acid, (C(0H) 2 -C00H) 2 (Ann.,
1883, 221, p. 230); and O. Doebner's preparation of mesotartaric
acid, the internally compensated tartaric acid, (CH(OH)-C60h) s

(calcium hypochlorite), and into bromopicrin, CBrjNOa, by bromine
water.


The action of chlorine upon di- and tri-oxybenzenes has been carefully investigated by Th. Zincke; and his researches have led to the discovery of many chlorinated oxidation products which admit of decomposition into cyclic compounds containing fewer carbon atoms than characterize the benzene ring, and in turn yielding open-chain or aliphatic compounds. In general, the rupture occurs between a keto group (CO) and a keto-carboxylate group (CCl), into which two adjacent carbon atoms of the ring are converted by the oxidizing and substituting action of chlorine. Decompositions of this nature were first discovered in the napthalene series, where it was found that derivatives of indene (and of hydroindenone and indene) and also of benzene resulted; Zincke then extended his methods to the disintegration of the oxybenzenes and obtained analogous results. R-pentene and aliphatic derivatives being formed (R-symbolizing a ring nucleus).

When treated with chlorine, pyrocatechol (1,2 or ortho-dioxybenzene) (1) yields a tetra-chloro ortho-quinone, which suffers further chlorination to hexachlor o-diketo-R-hexene (2). This substance is transformed into hexachlor-R-pentene oxycarboxylic acid (3) when digested with water; and chromic acid oxidizes this substance to hexachlor-R-pentene (4). The ring of this compound is ruptured by caustic soda with the formation of perchlorvinyl acetic acid (5), which gives on reduction ethidene propionic acid (6), a compound containing five of the carbon atoms originally in the benzene ring (see Zincke, Ber., 1894, 27, p. 3364) (the carbon atoms are omitted in some of the formulae).

Resorcin (1,3 or meta dioxybenzene) (1) is decomposed in a somewhat similar manner. Chlorination in glacial acetic acid solution yields hexachlorom-diketo-R-hexene (2), and, at a later stage, heptachlor-m-diketo-R-hexene (3). These compounds are both decomposed by water, the former giving dichloroacetate-trichloroacetic acid (4), which on boiling with water gives dichloromethylvinyl-sulphonic acid (5). The heptachlor compound when treated with caustic soda gives dichloroacetone-pentachloroacetic acid (6), which is hydrolysed by alkali to chloroform and pentachloroglutaric acid (7), and is converted by boiling water into tetrachlorodiketo-pentene (8). This latter compound may be chlorinated to perchloroacetocyclohexane (9), from which the corresponding acid (10) is obtained by treatment with water; alkali hydrolyses the acid to chloroform and dichlormaleic acid (11).

Resorcin, when oxidized, gives dityrosin, which G. Merling (Ann., 1894, 27, 28, p. 20) showed to be converted into 3-n-glutaric acid. HOOC-(CH$_2$)$_3$-COOH, when oxidized with potassium permanganate; according to D. Vörlander (Ber., 1895, 28, p. 2348) it is converted into 3-acetoctyloctic acid, CH$_2$CO-(CH$_2$)$_3$-COOH, when heated with hydrochloric acid.

Configuration of the Benzene Complex.—The development of the "structure theory" in about 1860 brought in its train an appreciation of the chemical structure of the derivatives of benzene. The pioneer in this field was August Kekulé, who, in 1865 (Ann., 137, p. 129; see also his Lehrbuch der organischen Chemie), submitted his well-known formula for benzene, so founding the "benzene theory" and opening up a problem which, notwithstanding the immense amount of labor since bestowed upon it, still remains imperfectly solved. Arguing from the existence of only one mono-substitution derivative, and of three di-derivatives (statements of which the rigorous proof was then wanting), he was led to arrange the six carbon atoms in a ring, attaching a hydrogen atom to each carbon atom; being left with the fourth carbon valencies, he mutually saturated these in pairs, thus obtaining the symbol I (see below).

The value of this ringed structure was readily perceived, but objections were raised with respect to Kekulé's disposal of the fourth valencies. In 1866 Sir James Dewar proposed an unsymmetrical form (II); while in 1867, A. Claus (Theoretische Betrachtungen und deren Anwendung zur Systematik der organischen Chemie) proposed his diagonal formula (III), and two years later, A. Ladenburg (Ber., 2, p. 140) devised his prismatic formula (IV), the six carbon atoms being placed at the six corners of a right equilateral triangular prism, with its plane projections (V, VI).

One of the earliest and strongest objections urged against Kekulé's formula was that it demanded two isomeric ortho-di-substitution derivatives; for if we number the letters in the order from 1 to 6, then the derivatives 1.2 and 1.6 should be different. Ladenburg submitted that if the 1.2 and 1.6 compounds were identical, then we should expect the two well-known tetrahalo-carboxylic acids, CH$_2$CO-CH$_2$COOH and CH$_2$:CH-CH$_2$:CH$_2$:COOH, to be identical. This view was opposed by Victor Meyer and Kekulé. The former pointed out that the supposed isomerism was not due to an arrangement of atoms, but to the disposition of a valency, and therefore it was doubtful whether such a subtle condition could exert any influence on the properties of the substance. Kekulé answered Ladenburg by formulating a dynamic interpretation of valency. He assumed that if we have an atom

---

To continue:

When phenol is oxidized in acid solution by chlorine, tetrachloroquinone is obtained, a compound also obtainable from hydroquinone. By conducting the chlorination in alkaline solution, A. Hantzsch (Ber., 1889, 22, p. 1293) succeeded in obtaining derivatives of o-diketo-R-hexene, which yield R-pentene and aliphatic compounds on decomposition. When thus chlorinated phenol (1) yields trichlor-o-diketo-R-hexene (2), which may be hydrolysed to an acid (3), which, in turn, suffers rearrangement to trichlor-R-pentene-oxycarboxylic acid (4). Bromine water oxidizes this substance to oxalic acid and tetrabromodichloroacetic acid. (5)

---

Footnotes:
1. It is now established that ortho compounds do exist in isomeric forms, instances being provided by chlor-, brom-, and amino-toluene, chlorophenol, chloroanilines, but arguments, e. g. E. Knoevenagel's theory of "monoisomerism," have been brought forward to cause these facts to support Kekulé.
connected by single bonds to (say) four other atoms, then in a certain unit of time it will collide with each of these atoms in turn. Now suppose two of the attached atoms are replaced by one atom, then this atom must have two valences directed to the central atom; and if we replace a third of these, the remaining two must collide once with each of the two monovalent atoms and twice with the divalent. Applying this notion to benzene, let us consider the impacts made by the carbon atom (1) which we shall assume to be doubly linked to the carbon atom (2). The double linkage is standing for the hydrogen atom. In the first unit of time, the impacts are 2, 6, 2; and in the second 6, 2, 6. If we represent graphically the impacts in the second unit of time, we perceive that they are both the double linkages, and to the carbon atoms 1 and 6, and the single linkage between 1 and 2. Therefore, according to Kekulé, the double linkages are in a state of continual oscillation, and if its dynamical notion of valency, or a similar hypothesis, be correct, then the difference between the 1 and 2, and their derivatives rests on the insufficiency of his formula, which represents the configuration during one set of oscillations only. The difference is only apparent, not real. An analogous oscillation prevails in the pyrazol nucleus, for L. Kroo (Ann., 1894, 279, p. 188) has shown that 3- and 5-sulphonic acid, was more favourably explained by his formula than by Ladenburg's. Other objections to Ladenburg's formula resulted from A. von Baeyer's researches (commenced in 1886) on the reduced phthalic acids. These compounds, he showed, were obtained, when the dihalogen derivatives of dibenzyl phenol, or of the corresponding dihalogen derivatives of dibenzyl 5-methyl pyrazol or of the corresponding dibenzylic derivatives, were reduced, are both meta- and ortho-dialdehydes, and the hexahydro acid obtained from the dihaloid dibenzyl 5-methyl pyrazol or of the corresponding dibenzylic derivatives, was reduced, were formed, and it is therefore quite possible. Kekulé (Ann., 1883, 221, p. 230), however, reinvestigated this acid; he showed that it was dibasic and not tribasic; that it gave tertaric acid on reduction; and, finally, that it was dioxyterephthalic if it be reduced. There is therefore no necessity, we think, to admit the existence of this substance readily follows from Kekulé's formula, while considerable difficulties are met with when one attempts an explanation based on Ladenburg's representatio. Kekulé also urged that the formation of the trichlorphenomalic acid, shown by him and O. Strecker to be a trihaloid acid, was more favourably explained by his formula than by Ladenburg's. The stronger argument against the ethylenoid linkages demanded by Kekulé's formula is provided by the remarkable stability towards oxidation and reducing agents which characterizes all benzenoid compounds. From the fact that reduction products containing either one or two double linkages behave exactly as unsaturated aliphatic compounds, being readily reduced or oxidized, and combining with the halogen elements and haloid acids, it seems probable that in benzenoid compounds the fourth valencies are symmetrically distributed in such a manner as to induce a peculiar stability in the molecule. Such a configuration was proposed in 1887 by H. E. Armstrong (J.C.S. Trans., 1887, p. 258), and shortly afterwards by Baeyer (Ann., 1888, 245, p. 103). In this formula, the so-called "centric formula," the assumption made is that the fourth valencies are simply directed towards the centre of the ring; nothing further is said about the fourth valencies except that they exert a pressure towards the centre. Claus maintained that Baeyer's view was identical with his own, for as in Baeyer's formula, the fourth valencies have a different function from the peripheral valencies, being united at the centre in a form of potential union, and not by an actual union. It is difficult to determine which configuration most accurately explains the observed facts; Kekulé's formula undoubtedly explains the synthetical production of benzenoid compounds most satisfactorily, and W. Markwald (Ann., 1893, 274, p. 331; 1894, 279, p. 14) has supported this formula from considerations based on the syntheses of the quinoline ring. Further researches by Baeyer, and upon various nitrogenous ring systems by E. Bamberger (a strong supporter of the centric formula), have shown that the nature of the substituent groups influences the distribution of the fourth valencies; therefore it may be concluded that in compounds the benzene nucleus appears to be capable of existence in two tautomeric forms, in the sense that each particular derivative possesses a definite constitution. The benzene nucleus presents a remarkable case, which must be considered in the formulation of any complete theory of valency. From a study of the reduction of compounds containing two ethylenic bonds united by a single bond, termed a "conjugated system," E. Thiele suggested a doctrine of "partial valencies, and the relative merits of the formulae of Kekulé, Claus and Dewar were next investigated by means of the reduction products of benzene, its being Baeyer's intention to detect whether double linkages were or were not present in the benzene complex. To follow Baeyer's results we must explain his nomenclature of the reduced benzene derivatives. He numbers the carbon atoms placed at the corners of a hexagon from 1 to 6, and each side in the same order, so that the carbon atoms 1 and 2 are connected by the 1, 2-dihydro derivative. A doubly linked pair of atoms is denoted by the sign Δ with the index of the side to the side; if there are two pairs of double links, then indices corre-
which assumes that in addition to the ordinary valencies, each doubly linked atom has a partial valency, by which the atom first interacts. When applied to benzene, a twofold conjugated system is suggested by which the partial valencies of adjacent atoms neutralize, with the formation of a potential double link. The stability of benzene is ascribed to this conjugation.

Physico-chemical properties have also been drawn upon to determine whether double unions are present in the benzene complex; but here the predictions of the observers apparently influence the nature of the conclusions to be drawn from such data. It is well known that singly, doubly and trebly linked carbon atoms affect the physical properties of substances, such as the refractive index, specific volume, and the heat of combustion; and by determining these constants for many substances, fairly definite values can be assigned to these groupings. The general question of the relation of the refractive index to constitution has been especially studied by J. W. Brühl, who concluded that benzene contained 3 double linkages; whereas, in 1901, Pellini (Gazetta, 31, p. 1) calculated that 9 single linkages were present. A similar contradiction apparently exists with regard to the specific volume, for while benzene has a specific volume corresponding to the valency of the methylbenzene, rather than to Kekulé's. The heat of combustion, as first determined by Julius Thomsen, agreed rather better with the presence of nine single unions. His work was repeated on a finer scale by M. P. E. Berthelot of Paris, and F. C. A. Stohmann of Leipzig; and the new data and the conclusions to be drawn from them formed the subject of much discussion, Brühl endeavouring to show how they supported Kekulé's formula, while Thomsen maintained that they demanded the benzene union to have a different heat of combustion from the acetylene union. Thomsen then investigated heats of combustion of various benzenoid hydrocarbons—benzene, naphthalene, anthracene, phenanthrene, &c.—in the crystalized state. It was found that the results were capable of expression by the empirical relation $C_{n}H_{2n}=104.3b+49.09a+105.47n$, where $C_{n}H_{2n}$ denotes the formula of the hydrocarbon, $m$ the number of single carbon linkings and $n$ the number of double linkings, $m$ and $n$ being calculated on the Kekulé formula. But, at the same time, the constants in the above relation are not identified with those in the corresponding expression empirically deduced from observations on fatty hydrocarbons; and we are therefore led to conclude that a benzene union is considerably more stable than an ethylene union.

Mention may be made of the absorption spectrum of benzene. According to W. N. Hartley (J.C.S., 1905, 87, p. 1822), there are six bands in the ultra-violet, while E. C. C. Baly and J. N. Collie (J.C.S., 1905, 87, p. 1332; 1906, 89, p. 524) record seven. These bands are due to molecular oscillations; Hartley suggests the carbon atoms to be rotating and forming alternately single and double linkages, the formation of three double links giving three bands, and of three single links another three; Baly and Collie, on the other hand, suggest the making and breaking of links between adjacent atoms, pointing out that there are seven combinations of one, two and three pairs of carbon atoms in the benzene molecule.

Stereo-chemical Conformations.—Simultaneously with the discussions of Kekulé, Ladenburg, Claus, Baeyer and others as to the merits of various plane forms of the benzene complex, there were published many suggestions with regard to the arrangement of the atoms in space, all of which attempted to explain the number of isomers and the equivalence of the hydrogen atoms. The development of stereo-isomerism at the hands of J. Wislicenus, Le Bel and van't Hoff has resulted in the introduction of another condition which formulae for the benzene complex must satisfy, viz., that the hydrogen atoms must all lie in one plane. The proof of this statement rests on the fact that if the hydrogen atoms were not co-planar, then substitution derivatives (the substituting groups not containing asymmetric carbon atoms) should exist in enantiomorphic forms, differing in crystal form and in their action on polarized light; such optical antipodes have, however, not yet been isolated.

The octahedral formula discussed by Julius Thomsen (Ber., 1886, 19, p. 2944) consists of the six carbon atoms placed at the corners of a regular octahedron, and connected together by the full lines as shown (I); a plane projection gives a hexagon with diagonals (II). Reduction to hexamethylene compounds necessitates the disruption of three of the edges of the octahedron, the diagonal linkings remaining intact, or, in the plane projection, three peripheral linkages; the hexamethylene ring assumes the form (III):

In 1888 J. E. Marsh published a paper (Phil. Mag. [4], 26, p. 426) in which he discussed various stereo-chemical representations of the benzene nucleus. (The stereo-chemistry of carbon compounds has led to the spatial representation of a carbon atom as being situated at the centre of a tetrahedron, the four valencies being directed towards the apices; see above, and ISOMERISM.) A form of the benzene formula, with a benzene ring of three pairs of tetrahedra, each pair having a side in common, and joining them up along the sides of a regular hexagon by means of their apices. This form, afterwards supported by Carl Graebe (Ber., 1892, 35, p. 526; see Marsh, idem.), shows some advantage in the proximity of the ortho-positions, but fails to explain the identity of 1,2 and 1,6 compounds. Arrangements connected with Claus' formula are obtained by placing six tetrahedra on the six sides of the benzene in such a way as to have the three pairs of tetrahedra all on one side, afterwards discussed by J. Loschmidt (Monats., 1890, 11, p. 28), would not give stereo-isomers; and the arrangement of placing the tetrahedra on alternate sides, a form afterwards developed by W. Yaubel (Journ. Pr. Chem., 1894 [2], 49, p. 308), has the advantage of bringing the meta-positions on one side, and the ortho- and para- on opposite sides, thus exhibiting the similarity actually observed between these series of compounds. Marsh also devised a form closely resembling that of Thomsen, in which the carbon atoms occupied the angles of a regular octahedron, and the diagonal linkings differed in nature from the peripheral, but differing from Thomsen's since rupture of the diagonal and peripheral bonds accompanied the reduction to hexamethylene.

We may also notice the model devised by H. Sachse (Ber., 1888, 21, 2530; Zeit. für phys. Chem., 11, p. 214; 23, p. 2062). Two parallel triangular faces are removed from a cardboard model of a regular octahedron, and on the remaining six faces tetrahedra are then placed; the hydrogen atoms are at the free angles. This configuration is, according to Sachse, more stable than any other form; no oscillation is possible, the molecule being only able to vibrate as a whole. (Collie, Journ. Chem., Chem. Soc., Tracts, p. 1013) considered in detail an octahedral form, and showed how by means of certain simple rotations of his system the formulae of Kekulé and Claus could be obtained as projections. An entirely new device, suggested by the late O. R. Meyer (Chem. Soc., Trans., p. 307), has the six carbon atoms to occupy six of the corners of a cube, each carbon atom being linked to a hydrogen atom, and by single bonds to two neighboring carbon atoms, the remaining valencies being directed to the unoccupied corners of the cube, three to each, where they are supposed to satisfy each other.

Condensed Nuclei.

Restricting ourselves to compounds resulting from the fusion of benzene rings, we have first to consider naphthalene, $C_{10}H_{8}$, which consists of two benzene rings having a pair of carbon atoms in common. The next members are the isomers anthracene and phenanthrene, $C_{14}H_{10}$, formed from three benzene nuclei. Here we shall only discuss the structure of these compounds in the light of the modern benzene theories; reference should be made
CHEMISTRY [ORGANIC]

58

to the articles NAPHTHALENE, ANTHRACENE and PHENANTHRENE for syntheses, decompositions, &c.

Naphthalene.—Of the earlier suggestions for the constitution of naphthalene we notice the formulae of Wreden (1) and (2), Berthelot and Bals (3), R. A. C. E. Erlenmeyer (4) and Adolf Claus (5).

The first suggestion is quite out of the question. C. Graebe in 1866 (Ann. 140, p. 20) established the symmetry of the naphthalene nucleus, and showed that whichever half of the molecule be oxidized the same phthalic acid results. Therefore formula (2), being unsymmetrical is wrong. The third formula based on Dewar’s benzene formula, which we have seen to be incorrect. Formula (4) is symmetrical and based on Kekulé’s formula: it is in full accord with the syntheses and decompositions of the naphthalene nucleus and the number of isomers found. In 1882 Claus suggested a combination of his own and Dewar’s benzene formulae. This is obviously unsymmetrical, consisting of an aliphatic and an aromatic nucleus; Claus explained the formation of the same phthalic acid from the oxidation of either nucleus by supposing that if the aromatic group be oxidized, the aliphatic residue assumes the character of a benzene nucleus. Bamberger opposed Claus’ formula on the following grounds:—

The molecule of naphthalene is symmetrical, since 2,7-dioxynaphthalene is readily esterified by methyl iodide and sulphuric acid to a dimethyl ether; and no more than two mono-substitution derivatives are known. The molecule is aromatic but not benzenoid; however, by the reduction of one half of the molecule, the other assumes a benzenoid character.

If β-naphthylamine and β-naphthol be reduced, tetrahydro products are obtained in which the aromatic or oxygen-bearing half of the molecule becomes aliphatic in character. The compounds so obtained, alicyclic-β-tetrahydro discourage and alicyclic-β-tetrahydro naphthalphol, closely resemble β-aminodibenzocyclohexenyl, C6H4(CH2)4CH2NH2, and β-oxo-dibenzocyclohexenyl, C6H4(CHOH)(CH2)4.

If a-naphthylamine and a-naphthol be reduced, the hydrogen atoms attach themselves to the non-substituted half of the molecule, and the compounds so obtained resemble aminodibenzocyclohexenyl, C6H4(CHOH)(CH2)4, and oxido-benzocyclohexenyl, C6H4(CHOH)(CH2)4. Bamberger’s observations on reduced quinoline derivatives point to the same conclusion, that condensed nuclei are not benzenoid, but possess an individual character, which breaks down, however, when the molecule is reduced.

It remains, therefore, to consider Erlenmeyer’s formula and those derived from the centric hypothesis. The former, based on Kekulé’s symbol for benzene, explains the decompositions and linkages of the ring, but the character of naphthalene is not in keeping with the presence of five double linkages, although it is more readily acted upon than benzene is. On the centric hypothesis two formulae are possible: (1) due to H.E. Armstrong, and (2) due to E. Bamberger.

In the first symbol it is assumed that one of the affinities of each of the two central carbon atoms common to the two rings acts into both rings, an assumption involving a somewhat wide departure from all ordinary views as to the manner in which affinity acts. This symbol harmonizes with the fact that the two rings are in complete sympathy, the one responding to every change made in the other. Then, on account of the relatively slight—because divided—influence which would be exercised upon the two rings by the two affinities common to both, the remaining four centric affinities of each ring would presumably be less attracted into the ring than in the case of benzene; consequently they would be more active outwards, and combination would set in more readily. When, as in the formation of naphthalene tetrachloride, for example, the one ring becomes saturated, the other might be expected to assume the normal centric form and become relatively inactive. This is absolutely the case. On the other hand, if substitution be effected in the one ring, and the affinities in that ring become attracted inwards, as apparently happens in the case of benzene, the adjoining ring should become relatively more active because the common affinities would act less into it. Hence, unless the radical introduced be one which exercises a special attractive influence, substitution should take place in preference to the previously unsubstituted ring. In practice this usually occurs; for example, on further bromination, a-bromonaphthalene yields a mixture of the (1.4) and (1.5) dibromonaphthalenes; and when nitro-naphthalene is either brominated, or nitrated or sulphonated, the action is practically confined to the second ring. The centric formula proposed by Bamberger represents naphthalene as formed by the fusion of two benzene rings, this indicates that it is a monocyclic compound of ten atoms of carbon. The formula has the advantage that it may be constructed from tetrahedral models of the carbon atom; but it involves the assumption that the molecule has within it a mechanism, equivalent in a measure to a system of railway points, which can readily close up and pass into that characteristic of benzene.

Anthracene and Phenanthrene.—These isomeric hydrocarbons, of the formula C10H8, are to be regarded as formed by the fusion of three benzenoid rings as represented by the symbols:

\[
\text{Anthracene} \quad \text{Phenanthrene}
\]

In both cases the medial ring is most readily attacked; and various formulae have been devised which are claimed by their authors to represent this and other facts. According to Armstrong, anthracene behaves unsymmetrically towards substituents, and hence one lateral ring differs from the other; he represents the molecule as consisting of one centric ring, the remaining medial and lateral ring being ethenoid. Bamberger, on the other hand, extends his views on benzene and naphthalene and assumes the molecule to be (1). For general purposes, however, the symbol (2), in which the lateral rings are benzenoid and the medial ring fatty, represents quite adequately the syntheses, decompositions, and behaviour of anthracene.

Phenanthrene is regarded by Armstrong as represented by (3), the lateral rings being benzenoid, and the medial ring fatty; Bamberger, however, regards it as (4), the molecule being entirely aromatic. An interesting observation by Baeyer, viz. that stilbene, C6H5·CH·CH·C6H5, is very readily oxidized, while phenanthrene is not, supports, in some measure, the views of Bamberger.

Heterocyclic Compounds.

During recent years an immense number of ringed or cyclic compounds have been discovered, which exhibit individual characters more closely resembling benzene, naphthalene, &c., than purely aliphatic substances, inasmuch as in general they contain double linkages, yet withstand oxidation, and behave as nuclei, forming derivatives in much the same way as benzene. By reduction, the double linkages become saturated, and compounds result which stand in much about the same relation to the original nucleus as hexamethylenedioxide to benzene. In general, therefore, it may be considered that the double linkages are not of exactly the same nature as the double linkage present in ethylene and ethyneloid compounds, but that they are analogous to the potential valencies of benzene. The centric hypothesis has been applied to these rings by Bamberger and others; but as in the previous rings considered, the ordinary
representation with double and single linkages generally represents the synthones, decompotions, &c; exceptions, however, are known where it is necessary to assume an oscillation of the double linkage. Five- and six-membered rings are the most stable and important, the last-named group resulting from the polymerization of many substances; three- and four-membered rings are formed with difficulty, and are easily ruptured; rings containing seven or more members are generally unstable, and are relatively little known. The elements which go to form heterocyclic rings, in addition to carbon, are oxygen, sulphur, selenium and nitrogen. It is remarkable that sulphur can replace two methine or CH groups with the production of compounds greatly resembling the original one. Thus benzene, (CH)$_n$, gives thiophene, (CH)$_n$S, from which it is distinctly distinguished; pyridine, (CH)$_n$N, gives thiazole, (CH)$_n$N-S, which is a very similar substance; naphthalene gives thionaphthen, C$_n$H$_{2n-1}$S, with which it shows great analogues, especially in the derivatives. Similarly a CH group may be replaced by a nitrogen atom with the production of compounds of similar stability; thus benzene gives pyridine, naphthalene gives quinoline and isoquinoline gives acridine and its $\alpha$ and $\beta$ analogues. Similarly, two or more methine groups may be replaced by the same number of nitrogen atoms with the formation of rings of considerable stability.

Most of the simple ring systems which contain two adjacent carbon atoms may suffer fusion with any other ring (also containing two adjacent carbon atoms) with the production of nuclei of greater complexity. Such condensed nuclei are, in many cases, more readily obtained than the parent nucleus. The more important analogues are derived from aromatic nuclei, benzene, naphthalene, &c; the ortho-di-derivatives of the first named, lending themselves particularly to the formation of condensed nuclei. Thus ortho-phenylene diamine yields the following products:

\[
\begin{align*}
\text{Thiophene} & \quad \text{Selenophene} \quad \text{Pyrrrole} \\
\text{Furazane} & \quad \text{Azoximes} \\
\end{align*}
\]

In some cases oxidation of condensed benzenoid-heterocyclic nuclei results in the rupture of the heterocyclic ring with the formation of a benzene dicarboxylic acid; but if the aromatic nucleus be weakened by the introduction of an amino group, then it is the benzenoid nucleus which is destroyed and a dicarboxylic acid of the heterocyclic ring is obtained.

Heterocyclic rings may be systematically surveyed from two aspects: (1) by increasing the rings with similar hetero-atoms according to the increasing number of carbon atoms, the so-called "homologous series"; or (2) by first dividing the ring systems according to the number of members constituting the ring, and then classifying these groups according to the nature of the hetero-atoms, the so-called "isologous series." The second method possesses greater advantages, for rings of approximate stability come in one group, and, consequently, their derivatives may be expected to exhibit considerable analogies.

As a useful preliminary it is convenient to divide heterocyclic ring systems into two leading groups: (1) systems resulting from simple internal dehydration (or similar condensations) of saturated aliphatic compounds—such compounds are: the internal anhydrides or cyclic ethers of the glycols and thioglycols (ethylene oxide, &c.); the cyclic alkyleneimides resulting from the splitting off of ammonia between the amino groups of diamino-paraffins (pyrrolidine, piperazine, &c.); the cyclic esters of oxyacrylic acids (lactones, lactides); the internal anhydrides of aliphatic acids (lacto-acetates); cyclic derivatives of dicarboxylic acids (anhydrides, imides, allenyl-esters, &c.). These compounds retain their aliphatic nature, and are best classified with open-chain compounds, into which, in general, they are readily converted. (2) Systems which are generally unsaturated compounds, of considerable stability, and behave as nuclei; these compounds constitute a well-individualized class exhibiting closer affinities to benzenoid substances than to the open-chain series.

The transition between the two classes as differentiated above may be illustrated by the following cyclic compounds, each of which contains a ring composed of four carbon atoms and one oxygen atom:

\[
\begin{align*}
\text{Tetramethylene oxide} \quad \text{Butyrolactone} \quad \text{Sebacic anhydride} \quad \text{Malonic anhydride} \\
\text{Furazane} \\
\end{align*}
\]

The first four substances are readily formed from, and converted into, the corresponding dihydroxy-open-chain compound; these substances are truly aliphatic in character. The fifth compound, on the other hand, does not behave as an unsaturated aliphatic compound, but its degradation is that of a nucleus, many substitution derivatives being capable of synthesis. Reduction, however, converts it into an aliphatic compound. This is comparable with the reduction of the benzene nucleus into hexamethylene, a substance of an aliphatic character.

True ring systems, which possess the characters of organic nuclei, do not come into existence in three- and four-membered rings, their first appearance being in penta-atomic rings. The three primary members are furanone, thiophene and pyrrole, each of which contains four methine or CH groups, and an oxygen, sulphur and imido (NH) member respectively; a series of compounds containing selenium is also known. The formulae of these substances are:

\[
\begin{align*}
\text{CH}=\text{CH} & \quad \text{CH}=\text{CH} \quad \text{CH}=\text{CH} \quad \text{Se} \\
\text{CH}=\text{CH}=\text{S} & \quad \text{Se} \\
\text{Furanone.} & \quad \text{Thiophene.} \quad \text{Selenophene.} \quad \text{Pyrrole.}
\end{align*}
\]

By substituting one or more CH groups in these compounds by nitrogen atoms, ring-systems, collectively known as azoles, result. Obviously, isomeric ring-systems are possible, since the carbon atoms in the original rings are not all of equal value. Thus furanone yields the following rings by the introduction of one and two nitrogen atoms:

\[
\begin{align*}
\text{CH}=\text{N} & \quad \text{N}=\text{CH} \\
\text{CH}=\text{CH} & \quad \text{CH}=\text{CH} \\
\text{Isoxazole.} & \quad \text{Oxazole.} \quad \text{Diazaoxides.}
\end{align*}
\]

Thiophene yields a similar series: isothiazole (only known as the condensed ring, isobenzothiazole), thiazole, diazothiophenes, pyrazoles, azo sulphides and thioziazole (the formulae are easily derived from the preceding series by replacing oxygen by sulphur). Thiophene also gives rise to triazoles, three nitrogen atoms being introduced. Selenophene gives the series: selenazole, diazo-selenide and diazaoxazine, corresponding to oxazole, diazo-oxazines and furazane. Pyrrole yields an analogous series: pyrazole, imidazole or glyoxaline, azimide or oso-tiazole, triazoles and tetaiazoles:
corresponding to paroxazine (para-oxazine). Pyridine gives origin to: pyridazine or ortho-diazine, pyrimidine or meta-diazine, pyrazine or para-diazine, oxotriazine, unsymmetrical triazine, symmetrical triazine, oxotetrazine and tetrazine. The skeletons of these types are (the carbon atoms are omitted for brevity):

We have previously referred to the condensation of heterocyclic ring systems containing two vicinal carbon atoms with benzene, napthalene and other nuclei. The more important nuclei of this type have received special and non-systematic names; when this is not the case, such terms as phen-, benzo-, naptho- are prefixed to the name of the heterocyclic ring. One or two benzene nuclei may suffer condensation with the furfuran, thiophene and pyrrol rings, the common carbon atoms being vicinal to the hetero-atom. The mono-benzo-derivatives are coumarone, benzothiophene and indole; the dibenzo-derivatives are diphenylene oxide, dibenzothiophene or diphenylene sulphide, and carbazole. Typical formulae are (R denoting O, S or NH):

Isomers are possible, for the condensation may be effected on the two carbon atoms symmetrically placed to the hetero-atom; these isomers, however, are more of the nature of internal anhydrides. Benz-oxazoles and -thiazoles have been prepared, benz-isoxazoles are known as indoxazenes; benzo-pyrazoles occur in two structural forms, named indazoles and isindazoles. Derivatives of osotiazol also exist in two forms—azimides and pseudo-azimides.

Proceeding to the six-membered hetero-atomic rings, the benzo-, dibenzo- and naphtho-derivatives are frequently of great commercial and scientific importance. a-pyrole condenses with the benzene ring to form coumarin and isocoumarin; benzo-γ-pyrole constitutes the nucleus of several vegetable colouring matters (chromium, isatin, quercetin, &c., which are derivatives of flavone or phenyl benzo-γ-pyrole); dibenzo-γ-pyrole is known as xanthone; related to this substance are fluorene (and fluoroscein), fluorone, fluoryne, &c. The pyridine ring condenses with the benzene ring to form quinoline and isquinoline; acridine and phantheridine are dibenzo-pyridines; napthalene gives rise to a-and β-naphthoquinolines and the antrazpyridines; anthracene gives anthraquinol; while two pyridine nuclei connected by an intermediate benzene nucleus give the phanthenalines. Naphthyridines and naphthotriazines result from the condensation of two pyridine and two quinoline nuclei respectively; and quinquinolines are unsymmetrical naphthyridine nuclei condensed with a benzene nucleus. Benzo-orthoxazines, -oxazones and -oxazines are known: dibenzopcarboxazone or phenoxyazine is the parent of a valuable series of dyestuffs; dibenzopcarbazolazine or dibenzopcarboxazine is important from the same aspect. Benzo-orthodiazines exist in two structural forms, chrysin and phthtalazine; benzo-meta-diazines are known as quinoazolines; benzo-para-diazines are termed quinazolines; the dibenzo-compounds are named phenazines, this last group including many valuable dyestuffs—indulins, safranines, &c. In addition to the types of compounds enumerated above we may also notice purin, tropine and the terpenes.

V. Analytical Chemistry

This branch of chemistry has for its province the determination of the constituents of a chemical compound or of a mixture of compounds. Such a determination is qualitative, the constituent being only detected or proved to be present, or quantitative, in which the amount present is ascertained. The methods of chemical analysis may be classified according to the type of reaction: (1) dry or blowpipe analysis, which consists in an examination of the substance in the dry condition; this includes such tests as ignition in a tube, ignition on charcoal in the blowpipe flame, fusion with borax, microcosmic salt or fluxes, and flame colorations (in quantitative work the dry methods are sometimes termed "dry assaying"); (2) wet analysis, in which a solution of the substance is treated with reagents which produce specific reactions when certain elements or groups of elements are present. In quantitative analysis the methods can be subdivided into: (a) gravimetric, in which the constituent is precipitated either as a definite insoluble compound by the addition of certain reagents, or electrolytically, by the passage of an electric current; (b) volumetric, in which the volume of a reagent of a known strength which produces a certain definite reaction is measured; (c) colorimetric, in which the solution has a particular tint, which can be compared with solutions of known strengths.

Historical.—The germ of analytical chemistry are to be found in the writings of the pharmacists and chemists of the alchemical period. The importance of ascertaining the proximate composition of bodies was clearly realized by Otto Tachenius; but the first systematic investigator was Robert Boyle, to whom we owe the introduction of the term analysis. Boyle recognized many reagents which gave precipitates with certain substances: he detected sulphuric and hydrochloric acids by the white precipitates formed with calcium chloride and silver nitrate respectively; ammonia by the white cloud formed with the vapours of nitric or hydrochloric acids; and copper by the deep blue solution formed by a solution of ammonia. Of great importance is his introduction of vegetable juices (the so-called indicators, q.v.) to detect acids and bases. During the phlogistic period, the detection of the constituents of compounds was considerably developed. Of the principal workers in this field we may notice Friedrich Hofmann, Andreas Sigismund Marggraf (who detected iron by its reaction with potassium ferrocyanide, and potassium and sodium by their flame colorations), and especially Carl Scheele and Torbern Olof Bergman. Scheele enriched the knowledge of chemistry by an immense number of facts, but he did not possess the spirit of working systematically as Bergman did. Bergman laid the foundations of systematic qualitative analysis, and devised methods by which the metals may be separated into groups according to their behaviour with certain reagents. This subdivision, which is of paramount importance in the analysis of minerals, was subsequently developed by Wilhelm August Lampadius in his Hand-buch zur chemischen Analyse der Mineralien (1801) and by John Friedrich A. Götting in his Praktische Anleitung zur prüfenden und zurlegenden Chemie (1802).

The introduction of the blowpipe into dry qualitative analysis by Axel Frederik Cronstedt marks an important innovation. The rapidity of the method, and the accurate results which it gave in the hands of a practised experimenter, led to its systematization by Jöns Jakob Berzelius and Johann Friedrich Ludwig Hesse, and its improvements by K. F. Pfaff who wrote Die Probekunst mit dem Läthrohre is a standard work on the subject. Another type of dry reaction, namely, the flame coloration, had been the subject of isolated notices, as, for example, the violet flame of potassium and the orange flame of sodium observed by Marggraf and Scheele, but a systematic account was wanting until Cartmell took the subject up. His results (Phil. Mag. 16, p. 382) were afterwards perfected by Robert Wilhelm Bunsen and Gustav Merz. Closely related to the flame-colorations, we have to notice the great services rendered by the spectroscope to the detection of elements. Rubidium, caesium, thallium, indium and gallium were first discovered by means of this instrument; the study of the rare earths is greatly facilitated, and the composition of the heavenly bodies alone determinable by it.

Quantitative chemistry had been all but neglected before the time of Lavoisier, for although a few chemists such as Tachenius, Bergman and others had realized the advantages which would accrue from a knowledge of the composition of
and of iodine and sulphurous acid to the estimation of copper and many other substances by Robert Wilhelm Bunsen, marks an epoch in the early history of volumetric analysis. Since then it has been rapidly developed, particularly by Karl Friedrich Mohr and J. Volhard, and these methods rank side by side in value with the older and more tedious gravimetric methods.

The detection of carbon and hydrogen in organic compounds by the formation of carbon dioxide and water when they are burned was first correctly understood by Lavoisier, and as he had determined the carbon and hydrogen content of these two substances he was able to devise methods by which carbon and hydrogen in organic compounds could be estimated. In his earlier experiments he burned the substance in a known volume of oxygen, and by measuring the residual gas determined the carbon and hydrogen. For substances of a difficultly combustible nature he adopted the method in common use to-day, viz. to mix the substance with an oxidizing agent—mercuric oxide, lead dioxide, and afterwards copper oxide—and absorb the carbon dioxide in potash solution. This method has been improved, especially by Justus v. Liebig; and certain others based on a different procedure have been suggested. The estimation of nitrogen was first worked out in 1836 by Jean Baptiste Dumas, and different processes have been proposed by Will and F. W. C. Kjeldahl and others. Methods for the estimation of the halogens and sulphur were worked out by L. Carus (see below, § Organic Analysis).

Only a reference can be made in this summary to the many fields in which analytical chemistry has been developed. Progress in forensic chemistry was only possible after the reactions of poisons had been systematized; a subject which has been worked out by many investigators, of whom we notice K. R. Fresenius, J. and R. Otto, and J. S. Stas. Industrial chemistry makes many claims upon the chemist, for it is necessary to determine the purity of a product before it can be valued. This has led to the estimation of sugar by means of the polarimeter, and of the calorific power of fuels, and the valuation of ores and metals, of coal-tar dyes, and almost all trade products.

The passing of the Food and Drug Acts (1875–1890) in England, and the existence of similar adulteration acts in other countries, have occasioned great progress in the analysis of foods, drugs, &c. For further information on this branch of analytical chemistry, see ADULTERATION.

There are no branch of technical chemistry, hygiene or pharmacy from which the analytical chemist can be spared, since it is only by a continual development of his art that we can hope to be certain of the purity of any preparation. In England this branch of chemistry is especially cared for by the Institute of Chemistry, which, since its foundation in 1877, has done much for the training of analytical chemists.

In the preceding sketch we have given a necessarily brief account of the historical development of analytical chemistry in its main branches. We shall now treat the different methods in more detail. It must be mentioned here that the reactions of any particular substance are given under its own heading, and in this article we shall only collate the various operations and outline the general procedure. The limits of space prevent any systematic account of the separation of the rare metals, the alkaloids, and other classes of organic compounds, but sources where these matters may be found are given in the list of references.

Qualitative Inorganic Analysis.

The dry examination of a substance comprises several operations, which may yield definite results if no disturbing element is present; but it is imperative that any inference should be confirmed by other methods.

1. Heat the substance in a hard glass tube. Note whether any moisture condenses on the cooler parts of the tube, a gas is evolved, a sublimate formed, or the substance changes colour.

Moisture is evolved from substances containing water of crystallization or decomposed hydrates. If it possesses an alkaline or acid reaction, it must be tested in the first case for ammonia, and in the second case for a volatile acid, such as sulphuric, nitric, hydrochloric, &c.
Any evolved gas must be examined. Oxygen, recognized by its power of igniting a glowing splinter, results from the decomposition of oxides of the noble metals, peroxides, chlorates, nitrates and other highly oxidized salts. Sulphur dioxide, recognized by its smell and acid reaction, results from the ignition of certain sulfites, sulphates, or a mixture of a sulphate with a sulphide. Nitrogen oxides, recognized by their colour and brown-red colour, result from the decomposition of nitrates. Carbon dioxide, recognized by turning liquid limewater milky, indicates decomposable carbonates or bicarbonates. Chalk, when moistened and ignited, gives carbon dioxide, which, by its colour and odour, result from decomposable haloids; iodine forms also a black sublimate. Cyanogen and hydrocyanic acid, recognizable by their odour, indicate decomposable cyanides. Sulphurised hydrogen sulphide is obtained from its odour, when viewed through a glass; water, and hydrosulphides. Ammonia, recognizable by its odour and alkaline reaction, indicates ammoniacal salts or cyanides containing water.

A substance may be formed of: sulphur—reddish-brown drops; cooling, to a yellow to brown solid, from sulphides or mixtures; iodine—violet vapour, black sublimate, from iodides, icodic acid, or mixtures; mercury and its compounds—metallic mercury forms minute globules, mercureic sulphide is black and becomes red, rubbing, mercureic chloride fuses before subliming, mercurous chloride does not fuse, mercurous iodide gives a yellow sublimate; arsenic and its compounds—metallic arsenic gives a grey mirror, arsenious oxide forms while shining crystals, arsenic sulphides give reddish-yellow sublimes which turn yellow on cooling; antimony oxide fuses and gives a yellow acicular sublimate; lead chloride forms a white sublimate after long and intense heating.

If the substance does not melt but changes colour, we may have presence of: lead—yellow in air, becoming brown on cooling; stannic oxide—white to yellowish brown, dirty white on cooling; lead oxide—from white or yellowish red to brownish-red, yellow on cooling; bismuth oxide—from white or pale yellow to orange-yellow, bismuth suboxide on cooling; osmic oxide—from white or yellowish white to dark brown, remaining dark brown on cooling (if it changes on cooling to a bright reddish-brown, it indicates cadmium oxide); copper oxide—from bright blue to deep purple, cooling, copper suboxide on cooling; ferric oxide—from brownish-red to black, brownish-red on cooling; potassium chromate—yellow to dark orange, fusing at a red heat.

2. Heat the substance on a piece of charcoal in the reducing flame of the blowpipe.

(a) The substance may fuse and be absorbed by the charcoal; this indicates particularly the alkaline metals.

(b) If the substance is not decomposed, we may have the presence of: silver—complex sulphides; silver or white lead; calcium—chlorides; barium—chlorides, sulphates; strontium—chlorates, hydrosulphides.

If the incrustation be white and readily volatile, arsenic is present; if more difficulty volatile and beads are present, antimony; zinc gives an incrustation yellow whilst hot, white on cooling, and volatile with difficulty; tin gives a pale yellow incrustation, which becomes white, white on cooling, and volatile with difficulty; iron gives a brown incrustation, which becomes yellow on cooling. When reducing or oxidizing fumes; lead gives a lemon-yellow incrustation turning sulphur-yellow on cooling, together with metallic malleable beads; bismuth gives metallic globules and a dark orange-yellow incrustation, which becomes lemon-yellow on cooling; bismuth gives a reddish-brown incrustation, which is removed without leaving a gleam by heating in the reducing flame; silver gives white metallic globules and a dark-red incrustation.

3. Heat the substance with a bead of microcosmic salt or borax on a platinum wire in the oxidizing flame.

(a) The substance dissolves readily and in quantity, forming a bead of clear liquid. This indicates the presence of metallic mercury.

(b) The substance dissolves slowly and in small quantity, and forms a colourless bead which remains so on cooling. Either silica or tin may be present, if silica be present, it gives the iron bead when heated with a little ferric oxide; if tin is present there is no change. If the bead is of metallic mercury, or any of the noble metals, or traces of precious metals, are quite insoluble in the bead, but float about in it.

4. Hold a small portion of the substance moistened with hydrochloric acid on a clean platinum wire in the fusion point of the Bunsen burner, and note any colour imparted to the flame.

Potassium gives a blue-violet flame which may be masked by the colorations due to sodium, calcium, and other elements. By viewing the flame through an indigo prism it appears sky-blue, violet and ultimately crimson, as the thickness of the prism is increased. Hydrocyanic acid, without liquid ammonia, gives a very yellow flame, which appears bright-green when viewed through green glass; strontium gives a crimson flame which appears purple or rose when viewed through blue glass; calcium gives an orange-red flame which appears fitch-green through green glass; indium gives a characteristic bluish-violet flame; copper gives an intense emerald-green coloration.

5. Film Reactions. These reactions are practised in the following manner:—A thread of asbestos is moistened and then dipped in the substance to be tested; it is then placed in the luminous point of the Bunsen flame, and a small porcelain basin containing cold water placed immediately over the asbestos. The formation of a film is noted. The operation is repeated with the thread in the oxidizing flame.

Any film formed in the first case is metallic, in the second it is the oxide. The metallic film is tested with 20% nitric acid and with hydrochloric acid, whereupon the metal dissolves; the oxide, immediately dissolves in the bleaching-powder. The black films of antimony and bismuth and the grey motiled film of mercury are slowly soluble in the acid, and untouched by bleaching-powder. The black films of the noble metals also dissolve in the acid, the lead film being also soluble in bleaching-powder. The oxide films of antimony, arsenic, tin and bismuth are white, that of bismuth slightly yellowish; lead yields a very pale yellow film, and cadmium a brown one; mercury and no other film. The oxide films (the metallic one in the case of mercury) are treated with hydrochloric acid and with ammonium sulphide, and from the changes produced the film can be determined (see F. M. Perkin, Qualitative Chemical Analysis, 1909).

Having completed the dry analysis we may now pass on to the wet and more accurate investigation. It is first necessary to get the substance into solution. Small portions should be successively tested with water, dilute hydrochloric acid, diute nitric acid, strong hydrochloric acid, and a mixture of hydrochloric and nitric acids, first in the cold and then with warming. Certain substances are insoluble in all these reagents, and other methods, such as the fusion with sodium carbonate and potassium nitrate, and subsequent treatment with sulphuric acid, must be employed. Some of these insoluble compounds can be detected by their colour and particular reactions. For further information on this subject, we refer the readers to Fresenius's Qualitative Analysis.
CHEMISTRY

barium. The solution contains magnesium, sodium and potassium, which are separately distinguished by the methods given under their own headings.

We now proceed with the examination of the various group precipitates. The white precipitate, if the barium chloride solution is boiled with water, and the solution filtered while hot. Any lead chloride dissolves, and may be identified by the yellow precipitate formed with potassium chromate. To the residue add ammonia, shake, then filter. Silver chloride goes into solution, and may be distinguished by the black precipitate formed by the rapid deposition of its hydrated form, which turns black in colour, consists of mercurocto-ammonium chloride, in which mercury can be confirmed by its ordinary tests.

The precipitate formed by sulphuretted hydrogen may contain the following compounds: lead, copper sulphides, black-bismuth sulphide, yellow cadmium and arsenious sulphides, orange-red antimony sulphide, brown stannous sulphide, dull-yellow stannic sulphide, and whith sulphur, the last resulting from the oxidation of sulphuretted hydrogen by ferric salts, chromates, &c. Warming with ammonium sulphide dissolves out the arsenic, antimony, and tin salts, which are precipitated by the addition of hydrochloric acid to the ammonium sulphide solution. The precipitate is shaken with ammonium carbonate, which dissolves the arsenic. Filter and cool with the solution by its particular tests. Dissolve the residue in hydrochloric acid and test separately for antimony and tin. The residue from the ammonium sulphide solution is warmed with dilute nitric acid. Any residue consists of black mercuric sulphide and possibly white lead sulphate, in which mercury is confirmed by its usual tests. The solution is evaporated with a little sulphuric acid and well cooled. The white precipitate consists of lead sulphate. To the filter add ammonia in excess: a white precipitate of ammolium is precipitated if mercury be present. Filter from the bismuth hydrate, and if copper is present, add potassium cyanide till the colour is destroyed, then pass sulphuretted hydrogen, and cadmium is precipitated as the yellow sulphide. If the filtrate contains sulphuretted hydrogen can be passed directly into the solution.

The next group precipitate may contain the white gelatinous aluminium hydrate, the greenish chromium hydrate, red ferric hydrate, and possibly zinc sulphate. The precipitate dissolves out the aluminium hydrate, which is precipitated by the addition of ammonium chloride.

The remaining tests are carried out separately.

The next group may contain black nickel and cobalt sulphides, fleshy-colored manganese sulphide, and white zinc sulphide. The two last are dissolved out by cold, very dilute hydrochloric acid, and the residue is tested for nickel and cobalt. The solution is boiled till free from sulphuretted hydrogen and treated with excess of permanganate. When in black, the residue precipitated on standing indicates manganese. The solution with ammonium sulphide gives a white precipitate of zinc sulphide.

The next group may contain the white calcium, barium and strontium hydrate. The black precipitate may give information as to which elements are present. The carbonates are dissolved in hydrochloric acid, and calcium sulphate solution is added to a portion of the solution. An immediate precipitate indicates calcium; if no precipitate forms, add a solution of ammonia, and if the precipitate is decomposed by heating, it is calcium carbonate. If barium is present, the solution of the carbonates in hydrochloric acid is evaporated and digested with strong alcohol for some time; barium carbonate, which is nearly insoluble in alcohol, is thus separated, the remainder being precipitated by a few drops of hydrofluoric acid, and may be confirmed by the ordinary tests. The solution free from barium is treated with ammonia and ammonium sulphate, which precipitates strontium, and the calcium in the solution may be identified by the white precipitate with ammonium oxalate.

Having determined the bases, it remains to determine the acid radicals. There is no general procedure for these operations, and it is customary to test for the acids separately by special tests; these are given in the articles on the various acids. A knowledge of the solubility of salts considerably reduces the number of acids likely to be present, and affords evidence of great value to the analyst (see A. M. Comey, Dictionary of Chemical Solubilities). In the above account we have indicated the procedure adopted in the analysis of a complex mixture of salts. It is a question of taste whether in such cases the precisions which can only be conveniently acquired by experience; a sound appreciation of analytical methods is only possible after the reactions and characters of individual substances have been studied, and we therefore refer the reader to the articles on the particular elements and compounds for more information on this subject.

Quantitative Inorganic Analysis.

Quantitative methods are divided into four groups, which we now pass on to consider in the following sequence: (a) gravimetric, (b) volumetric, (γ) electrolytic, (δ) colorimetric.

(a) Gravimetric.—This method is made up of four operations: (1) a weighed quantity of the substance is dissolved in a suitable solvent; (2) a particular reagent is added which precipitates the substance; (3) the precipitate is filtered, washed and dried; (4) the filter paper containing the precipitate is weighed either as a tared filter, or incinerated and ignited either in air or in any other gas, and then weighed.

(1) Accurate weighing is all-important; for details of the various appliances and methods see Weighing Machines. (2) No general directions can be given as to the method of precipitation. Sometimes it is necessary to allow the solution to stand for a considerable time either in the warm or cold or in the light or dark; to work with cold solutions until the matter has reacted completely, and to filter the precipitate and substance and reagents. Details will be found in the articles on particular metals. (3) The operation of filtration and washing is very important. If the substance to be weighed changes in composition on evaporation, the filter paper must be washed, i.e., a filter paper which has been previously heated to the temperature at which the substance is to be dried until its weight is constant. If the precipitate settles readily, the supernatant liquor may be removed from the precipitate, or the filter paper added to the precipitate and again decanted. By this means most of the washing, i.e., freeing from the other substances in the solution, can be accomplished in the precipitating vessel. If, however, the precipitate refuses to settle, it is directly transferred to the filter paper, the last is transferred to the precipitating vessel, with a piece of rubber, and the liquid is allowed to drain through. It is washed by ejecting a jet of water, ammonia or other prescribed liquid on to the side of the filter paper until the paper is nearly full. The filter paper is then covered with a nearly completely filled and emptied the funnel than by endeavouring to keep the funnel full. The washing is continued until the filtrate is free from salts or acids. (4) After washing, the funnel containing the filter paper is weighed repeatedly until the weight suffers no change; then knowing the weight of the filter paper, the weight of the precipitate is obtained by subtraction. If the precipitate may be ignited, it is transferred to a clean, weighed and recently ignited crucible, and the filter paper is ignited and intimately mixed with the crucible and the whole ignited. After ignition, it is allowed to cool in a desiccator and then weighed. Knowing the weight of the crucible and of the ash of the filter paper, the weight of the precipitate is determined. The calculation of the percentage of the particular constituent is simple. We know the amount present in the precipitate and since the same amount is present in the quantity of substance experimented with, we have only to work out a sum in proportion.

(b) Volumetric.—This method is made up of three operations:—(1) preparation of a standard solution; (2) preparation of a solution of the substance; (3) titration, or the determination of what volume of the standard solution will occasion a known and definite reaction with a known volume of the test solution.

(1) In general analytical work the standard solution contains the equivalent weight of the substance in grammes dissolved in a litre of water. To each volume 1 cubic centimetre of the normal solution of sodium carbonate contains 53 grammes per litre, of sodium hydrate 40 grammes, of hydrochloric acid 36-5 grammes and so on. By taking 1/8th or 1/4th of these quantities, dec normal solutions are obtained. We see therefore that a cubic centimetre of a normal sodium carbonate solution will exactly neutralise 0-049 gramme of sulphuric acid, 0-0365 gramme of hydrochloric acid, i.e., the equivalent quantities, and similarly for nitric acid and other normal solutions. Unfortunately the term normal is sometimes given to solutions which are neither normal: for example, iodine, sodium thiosulphate, &c. In technical analysis, where a solution is used for one process only, it may be prepared so that 1 c.c. is equal to 01 gramme of the substance to be estimated. A certain amount of this solution is applied in another determination additional calculations are necessary. Standard solutions are prepared by weighing out the exact amount of the pure substance and dissolving it in water, or by dissolving the pure substance in water and diluting it to its exact strength by gravimetric or other means, and then correcting it for any divergence. This may be exemplified in the case of alkaliometry. Pure sodium carbonate is prepared by igniting the common salt, washed and dried until constant weight, and then dissolving 53 c.c. of sodium hydrate, making up to 1 litre. The solutions are titrated (see below) and the acid solution diluted until equal volumes are exactly equivalent. A standard sodium hydrate solution can be prepared by dissolving 753 grammes of sodium hydrate, making up to a litre, and diluting until one cubic centimetre is exactly equivalent to one cubic centimetre of the sulphuric acid. Similarly, normal solutions of hydrochloric and nitric acids, &c, can be prepared. Where a determination is of composition on keeping, such as potassium permanganate, iodine,
sodium hydrate, &c., it is necessary to check or re-standardize it periodically.

(2) The preparation of the solution of the substance consists in dissolving an accurately determined weight, and making up the volume with water. The order and methods of treatment are as follows:

(3) The titration is conducted by running the standard solution from a burette into a known volume of the test solution, which is usually transferred from the stock-bottle to a beaker or basin by means of a pipette. The yellow substance, which is a ferricyanide, is used for the determination of copper oxide, which must be freshly ignited before use on account of its hygroscopic nature. Lead chromate is sometimes used, and many other substances, such as platinum, manganese dioxide, &c., have been suggested. The procedure for a combustion is as follows:

A hard glass tube slightly longer than the furnace and 12 to 15 mm. in diameter is thoroughly cleansed and packed as shown in fig. 1. The space a must allow for the inclusion of a copper spiral if the substance contains nitrogen, and a silver spiral if halogens be present. When otherwise nitrous oxides and the halogens may be condensed in the absorption apparatus; b contains copper oxide; c is a space for the insertion of a porcelain or platinum boat containing a weighed quantity of the substance; d is a copper spiral. The end of the oxygen was passed through and oxygen supply with an intermediate drying apparatus. The other end is connected with the absorption vessels, which consist of a tube (e) containing calcium chloride, and a set of bulbs (f) containing potassium solution. Various forms of potash may be employed; fig. 2 is Liebig's, fig. 3 Mohr's, and fig. 4 is a more recent form, of which special variations have been made by Anderson, Gomberg, Delisle and others. After having previously roasted the tube and copper oxide, and reduced the copper spiral a, the weighed calcium chloride tube and potash bulbs are put in position, the boat containing the substance is inserted (in the case of a difficultly combustible substance it is desirable to form it with the spiral d). The absorbing agent is prepared by a current of dry air, and the air passes through the tube. The success of the operation depends upon the slow burning of the substance. Towards the end the heat and the oxygen supply are increased. When there is no more absorption possible, oxygen is passed through, and the oxygen supply is decreased in order to maintain the same temperature of the room. The increase in weight of the calcium chloride tube gives the weight of water formed, and of the potash bulbs the carbon dioxide.

Liquids are amenable to the same treatment, but special care must be taken so that they volatilize slowly. Difficultly volatile liquids may be weighed directly into the boat; volatile chlorine is obtained by fusing with zinc dust, and the chlorine is absorbed by a bulb of potassium hydroxide solution. When chlorine is present, it must be removed entirely before the starting of the absorption, or the chlorine will combine with the alkali and form a salt, which is then lost in the absorption vessel. By this method, chlorine and bromine may be determined in the same vessel.

The length of time and other disadvantages attending the combustion method have caused investigators to devise other processes. In 1835 C. Brunner described a method for oxidizing the carbon to carbon dioxide, which could be estimated by the usual methods, by heating the substance with potassium bichromate and sulphuric acid. The process is slow, and we may hope that with subsequent improvements it may be adapted to all classes of organic compounds. The oxidation, which is effected by chromic acid and sulphuric acid, is conducted in a flask provided with a funnel and escape tube, and the carbon dioxide is passed off through the escape tube in such a manner that the acid and other materials are kept in the flask for the requisite time.
The weight of carbon dioxide evolved. C. F. Cross and E. J. Bevan collected the carbon dioxide obtained in this way over mercury. They also showed that carbon monoxide was given off towards the end of the reaction, and oxygen was evolved unless the temperature exceeded 100°.

Methods depending upon oxidation in the presence of a contact substance have come into favour in recent years. That of M. Dennstedt, which was first proposed in 1802, the substance is vaporized in a tube containing at one end platinum foil, platinum nitrate, or platinumized asbestos. The platinum is maintained at a bright red heat, either by a gas flame or by an electric furnace, and the vapour is passed over it in a current of oxygen. If nitrogen be present, a boat containing dry lead peroxide, heated to 520°, is inserted, the oxide decomposing any nitrogen peroxide which may be formed. The absorbent is quantitatively taken up in any halogen and sulphur which may be present. The process is therefore adapted to the simultaneous estimation of carbon, hydrogen, the halogens, and phosphorus.

Nitrogen is estimated by (1) Dumas' method, which consists in heating the substance with copper oxide and measuring the volume of nitrogen of the nitrogen liberated; (2) by Will and Varrentrapp's method, in which the substance is heated with soda-lime, and the ammonia evolved is absorbed in hydrochloric acid, and then precipitated as ammonium chloroplatinate or estimated volumetrically; or (3) by Kjeldahl's method, in which the substance is dissolved in concentrated sulphuric acid, potassium permanganate added, the liquid diluted and boiled with caustic soda, and the evolved ammonia absorbed in hydrochloric acid and estimated as in Will and Varrentrapp's method.

**Dumas' Method**—In this method the operation is carried out in a hard glass tube sealed at one end and packed as shown in fig. 5. The substance is heated with cold soda-lime, and the ammonia evolved is absorbed in hydrochloric acid and then precipitated as ammonium chloroplatinate or estimated volumetrically. The absorbent is quantitatively taken up in any halogen and sulphur which may be present. The process is therefore adapted to the simultaneous estimation of carbon, hydrogen, the halogens, and phosphorus.

Nitrogen is estimated by (1) Dumas' method, which consists in heating the substance with copper oxide and measuring the volume of nitrogen of the nitrogen liberated; (2) by Will and Varrentrapp's method, in which the substance is heated with soda-lime, and the ammonia evolved is absorbed in hydrochloric acid and then precipitated as ammonium chloroplatinate or estimated volumetrically; or (3) by Kjeldahl's method, in which the substance is dissolved in concentrated sulphuric acid, potassium permanganate added, the liquid diluted and boiled with caustic soda, and the evolved ammonia absorbed in hydrochloric acid and estimated as in Will and Varrentrapp's method.

**Dumas' Method**—In this method the operation is carried out in a hard glass tube sealed at one end and packed as shown in fig. 5. The substance is heated with cold soda-lime, and the ammonia evolved is absorbed in hydrochloric acid and then precipitated as ammonium chloroplatinate or estimated volumetrically. The absorbent is quantitatively taken up in any halogen and sulphur which may be present. The process is therefore adapted to the simultaneous estimation of carbon, hydrogen, the halogens, and phosphorus.
CHEMISTRY

For the complete determination of the chemical structure of any compound, three sets of data are necessary: (1) the empirical chemical composition of the molecule; (2) the constitution, i.e., the manner in which the atoms are linked together; and (3) the configuration of the molecule, i.e., the arrangement of the atoms in space. Identity in composition, but difference in constitution, is generally known as "isomerism" (q.v.), and compounds satisfying this relation differ in many of their physical properties. If, however, two compounds only differ with regard to the spatial arrangement of the atoms, the physical properties may be (1) for the most part identical, differences, however, being apparent with regard to the action of the molecules on polarized light, as is the case when the configuration is due to the presence of an asymmetric atom (optical isomerism); or (2) both chemical and physical properties may be different when the configuration is determined by the disposition of the atoms or groups attached to a pair of doubly-linked atoms, or to two members of a ring system (geometric isomerism or allo-isomerism). Three sets of physical properties may therefore be looked for: (1) depending on composition, (2) depending on constitution, and (3) depending on configuration. The first set provides evidence as to the molecular weight of a substance: these are termed "colligative properties." The second and third sets elucidate the actual structure of the molecule: these are known as "constitutional properties."

In any attempts to gain an insight into the relations of the physical properties and chemical composition of substances, the fact must never be ignored that a comparison can only be made when the particular property under consideration is determined under strictly comparable conditions, in other words, when the molecular states of the substances experimented upon are identical. This is readily illustrated by considering the properties of gases—the simplest state of aggregation. According to the law of Avogadro, equal volumes of different gases under the same conditions of temperature and pressure contain equal numbers of molecules; therefore, since the density depends upon the number of molecules present in unit volume, it follows that for a comparison of the densities of gases, the determinations must be made under coincident conditions, or the observations reduced or re-computed for coincident conditions. When this is done, such densities are measures of the molecular weights of the substances in question.

Volume Relations:—When dealing with colligative properties of liquids it is equally necessary to ensure comparability of conditions. In the article Condensation of Gases (see also MOLECULE) it is shown that the characteristic equation of gases and liquids is conveniently expressed in the form$r = k T$; this equation, which is mathematically deducible from the kinetic theory of gases, expresses the behaviour of gases, the phenomena of the critical state, and the behaviour of liquids; solits are not accounted for. If we denote the critical volume, pressure and temperature by $V_c$, $P_c$ and $T_c$, then it may be shown, either by considering the characteristic equation as a perfect cube in $v$ or by using the relations that $dP/dv = 0$, $d^2P/dv^2 = 0$ at the critical point, that $V_c = 3b$, $P_c = 1/2T_c^2$, $T_c = 8a/27b^2$. Eliminating $a$ and $b$ between these relations, we derive $P_a = 3V_2T_2$, a relation which should hold between the critical constants of any substance. Experiment, however, showed that while the quotient on the left hand of this equation was fairly constant for a great number of substances, yet its value was not $\frac{3}{2}R$ but $\frac{1}{2}R$; this means that the critical density is, as a general rule, 3$\times$7 times the theoretical density. Deviation from this rule indicates molecular dissociation or association.

By actual observations it has been shown that ether, alcohol, many esters of the normal alcohols and fatty acids, benzene, and its halogen substitution products, have critical constants agreeing with this originally empirical law, due to Sydney Young and Thomas: acetic acid behaves abnormally, pointing to associated molecules at the critical point.

The critical volume provides data which may be tested for additive relations. Theoretically the critical volume is three times the volume at absolute zero, i.e. the actual volume of the molecule; this is obvious by considering the result of making $T = \infty$ in the characteristic equation. Experimentally (by extrapolation from the law of the rectilinear section of the curve) the critical volume is four times the volume at absolute zero (see CONDENSATION OF GASES). The molecular volume can only be determined for additive relations is to determine the property for a number of elements, and then investigate whether these values hold for the elements in combination. Want of data for the elements, however, restricts this method to narrow limits, and hence an indirect method is necessary. It is found that isomers have nearly the same critical volume, and that equal differences in molecular content occasion equal differences in critical volume. For example, the difference due to the increase of CH$_2$ is about 56-6, as is shown in the following table:

<table>
<thead>

Since the critical volume of normal pentane CH$_5$H$_{12}$ is 397-2, we have H$_2$C$\cdot$CH$_3$ = 5CH$_3$ = 207-2 = 5x56-6 = 242, and C$\cdot$H$_2$CH$_3$ = 32-4. The critical volume of oxygen can be deduced from the data of the above table, and is found to be 29, whereas the experimental value is 25.

The researches of H. Kopp, begun in 1842, on the molecular volumes of the liquids, i.e. the volume occupied by one gramme molecular weight of a substance, of liquids measured at their boiling-point under atmospheric pressure, brought to light a series of additive relations which, in the case of carbon compounds, render it possible to predict, in some measure, the composition of the substance. In practice it is generally more convenient to determine the density, the molecular volume being then obtained by dividing the molecular weight of the substance by the density. By the indirect method we have derived the following atomic volumes:

<table>
<thead>
<tr>
<th>C</th>
<th>O</th>
<th>H</th>
<th>Cl</th>
<th>Br</th>
<th>I</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>12-2</td>
<td>5-5</td>
<td>22-8</td>
<td>28-7</td>
<td>37-5</td>
<td>22-6</td>
</tr>
</tbody>
</table>

These values hold fairly well when compared with the experimental values determined from other compounds, and also with the molecular volumes of the elements of the periodical system. Thus, the usually observed densities of liquid chlorine and bromine at the boiling-points are 1-56 and 2-96, leading to atomic volumes 22-7 and 26-9, which closely correspond to Kopp's values deduced from organic compounds.

These values, however, require modification in certain cases, for discrepancies occur which can be reconciled in some cases by assuming that the atomic volume of a polyvalent element varies according to the distribution of its valencies. Thus a double bond of oxygen, as in the carbonyl group $\text{CO}$, reduces the atomic volume by more than a single bond, as in the hydroxyl group $\text{OH}$, being about 12-2 in the first case and 7-8 in the second. Similarly, an increase of volume is associated with doubly and trebly linked carbon atoms.

Recent researches have shown that the formula originally proposed by Kopp—$V/3R$—that the specific volume of a liquid compound (molecular volume) at its boiling-point is equal to the sum of the specific volumes of its constituents (atomic volumes), and that every element has a definite atomic volume in its compound—is not exact, for isomers have different specific volumes, and the volume for an increase of CH$_4$ in different homologous series is by no means constant; for example, the difference among the esters of the fatty acids is about 7, whereas for the alcohols it is about 10. We may therefore conclude that the molecular volume depends more upon the internal structure of the molecule than its empirical content.

W. Ostwald (Lehr, der Org. Chem.), after an exhaustive review of the matter at hand, concluded that simple additive means exact. Thus he did exist but with considerable deviations, which he ascribed to differences in structure. In this connexion we may notice W. Städel's determinations:

CH$_3$(CH$_3$)$_3$ = 108, CH$_3$Br$\cdot$CH$_3$ = 96-5,
CH$_3$Cl$\cdot$CH$_3$Cl = 102-8, CH$_3$Br$\cdot$CH$_3$Cl = 88.
These differences do not appear at the critical point, and hence the critical volumes are not strictly additive.

Theoretical considerations as to how far Kopp was justified in choosing the boiling-points under atmospheric pressure as being comparable to those for constant temperature. If we express the pressure, volume and temperature as fractions of the critical constants, then, calling these fractions the "reduced" pressure, volume and temperature, and denoting them by \( P, V \) and \( T \) respectively, the characteristic equation becomes \((\frac{P + a}{P})^\frac{2}{3} (\frac{V}{V_a})^\frac{1}{3} = B\), which has the same form for all substances. Obviously, therefore, liquids are comparable when the pressures, volumes and temperatures are expressed in equal fractions of the critical constants, and in view of the extremely slight compressibility of liquids, atmospheric pressure may be regarded as a coincident condition; also C. M. Guldberg pointed out that for the most diverse substances the absolute volume at the boiling-point is not only about two-thirds of the critical volume. Hence within narrow limits Kopp's determinations were carried out under coincident conditions, and therefore any regularities presented by the critical volumes should be revealed in the specific volumes at the boiling-points.

The connection between the density and chemical composition of solids has not been investigated with the same completeness as in the case of gases and liquids. The relation between the atomic volumes and the atomic weights of the solid elements exhibits the periodicity which generally characterizes the elements. The molecular volume is additive in certain cases, in particular of analogous compounds of simple constitution. For instance, constant differences are found between the bromides, chlorides and iodides of sodium and potassium:

According to H. Schroeder the silver salts of the fatty acids exhibit additive relations; an increase in the molecule of \( \text{CH}_3 \) causes an increase in the molecular volume of about 15.3.

### Thermal Relations

#### Specific Heat and Composition

The nature and experimental determination of specific heats are discussed in the article CALORIMETRY; here will be discussed the relations existing between the heat capacities of elements and compounds.

In the article THERMODYNAMICS it is shown that the amount of heat required to raise a given weight of a gas through a certain range of temperature is different according as the gas is maintained at constant pressure, the volume increasing, or at constant volume, the pressure increasing.

A gas, therefore, has two specific heats, generally denoted by \( C_p \) and \( C_v \), when the quantity of gas taken as a unit is one gramme molecular weight, the range of temperature being \( 1^\circ \). It may be shown that \( C_p - C_v = R \), where \( R \) is the gas-constant, i.e., \( R \) in the equation \( P \cdot V = RT \). From the ratio \( C_p/C_v \), conclusions may be drawn as to the molecular condition of the gas. By considerations based on the kinetic theory of gases (see MOLECULE) it may be shown that when no energy is utilized in separating the atoms of a molecule, this ratio is \( 5/3 = 1.67 \). If, however, an amount of energy \( a \) is taken up in separating atoms, the ratio is expressible as \( C_p/C_v = (5/3 + a)/(5/3 + a) \), which is obviously greater than \( 5/3 \). \( C_p \) and \( C_v \) are specific heats of the same substance. The ratio \( C_p/C_v \) may be readily tested for, the ratio \( C_p/C_v \) is capable of easy experimental determination. It is observed that merycury, sulphur, argon and its associates (neon, krypton, &c.) have the value \( 1.67 \); hence we conclude that these gases exist as monatomic molecules. Oxygen, nitrogen, hydrogen and carbon monoxide have the value \( 1.4 \); these gases have diatomic molecules, a fact capable of demonstration by other means. Hence it may be inferred that this value is typical for diatomic molecules. Similarly, greater atomic complexity is reflected in a further decrease in the ratio \( C_p/C_v \). The following table gives a comparative view of the specific heats and the ratio for molecules of variable atomic content.

The abnormal specific heats of the halogen elements may be due to a loosening of the atoms, a preliminary to the dissociation into monatomic molecules which occurs at high temperatures. In the more complex gases the specific heat varies considerably with temperature; only in the case of monatomic gases does it remain constant.

Le Chatelier (Zeit. f. phys. Chem. i, 456) has given the formula \( C_p = a + bT \), where \( a \) is a constant depending on the complex constitution of the gas, and \( b \) a measure of the mean heat of condensation at constant pressure at any temperature \( T \) (reckoned on the absolute scale). For a further discussion of the ratio of the specific heats see MOLECULE.

#### Specific Heats of Solids

The development of the atomic theory and the subsequent determination of atomic weights in the opening decades of the 19th century inspired A. T. Petit and P. L. Dulong to investigate relations (if any) existing between specific heats and the atomic weight. Their observations on the solid elements led to a remarkable generalization, now known as Dulong and Petit's law. This states that the atomic heat (the product of the atomic weight and specific heat) of all elements is a constant quantity. The value of this constant when \( H = 1 \) is about 6.4; Dulong and Petit, using \( O = 1 \), gave the value 38, the specific heat of water being unity in both cases. This law—purely empirical in origin—was strengthened by Berzelius, who redetermined many specific heats, and applied the law to determine the true atomic weight from the equivalent weight. At the same time he perceived that specific heats varied with temperature and also with allopore, e.g., graphite and diamond. The results of Berzelius were greatly extended by Hermann Kopp, who recognized that carbon, boron and silicon were exceptions to the law. He regarded these anomalies as solely due to the chemical nature of the elements, and ignored or regarded as insignificant such factors as the state of aggregation and change of specific heat with temperature.

The specific heats of carbon, boron and silicon subsequently formed the subject of elaborate investigations by H. F. Weber, who showed that with rise of temperature the specific (atomic) heat increases, finally attaining a fairly constant value; diamond, graphite and the various amorphous forms of carbon having the value \( 9.6 \) at \( 100^\circ \); and silicon \( 6.68 \) at \( 232^\circ \); he concluded that boron attained a constant value of \( 5.5 \). Nilson and Petterson's observations on beryllium and germanium have shown that the atomic heats of these metals increase with rise of temperature, finally becoming constant at higher temperatures. (Phil. Trans. 1900, p. 232) investigated nickel and cobalt over a wide range of temperature (from \( -182^\circ \) to \( 100^\circ \)); his results are:

<table>
<thead>
<tr>
<th>Nickel</th>
<th>Cobalt</th>
</tr>
</thead>
<tbody>
<tr>
<td>From ( -182^\circ ) to ( -78^\circ )</td>
<td>( 4 )</td>
</tr>
<tr>
<td>( -78^\circ ) to ( 15 )</td>
<td>( 4 )</td>
</tr>
<tr>
<td>( 15^\circ ) to ( 100^\circ )</td>
<td>( 5 )</td>
</tr>
<tr>
<td>( 15^\circ ) to ( 100^\circ )</td>
<td>( 6 )</td>
</tr>
</tbody>
</table>

It is evident that the atomic heats of these intimately associated elements approach nearer and nearer as we descend in temperature, tending to the value 4. Other metals were tested in order to determine if their atomic heats approximated to this value at low temperatures, but with negative results.

It is apparent that the law of Dulong and Petit is not rigorously true, and that deviations are observed which invalidate the law as originally framed. Since the atomic heat of the same element varies with its state of aggregation, it must be concluded that some factor taking this into account must be introduced; moreover, the experimental determination of atomic heat is subject to many other factors.

We now proceed to discuss molecular heats of compounds, that is, the product of the molecular weight into the specific heat. The earliest generalization in this direction is associated with F. E. Neumann, who, in 1831, deduced from observations on many carbonates (calcium, magnesium, ferrous, zinc, barium and lead) that stoichiometric quantities (equimolecular weights) of compounds possess the same heat capacity. This is spoken of as "Neumann's law." Regnault confirmed Neumann's observations, and showed that the molecular heat depended on the number of atoms present, equimolecular compounds having the same molecular heat. Kopp systematized the earlier observations,
and, having made many others, he was able to show that the molecular heat was an additive property, i.e. each element retains the same heat capacity when in combination as in the free state. This has received confirmation by the researches of W. A. Tilden (Phil. Trans., 1904, 203 A, p. 139) for those elements whose atomic heats vary considerably with temperature.

The specific heat of a compound may, in general, be calculated from the specific heats of its constituent elements. Conversely, if the specific heats of a compound and its constituent elements, except oxygen, are known, then the unknown heat of a new compound is readily deducible. Similarly, by taking the difference of the molecular heats of compounds differing by one constituent, the molecular (or atomic) heat of this constituent is directly obtained. By this method it is shown that water is present as "water of crystallization," behaves as if it were ice.

**Deductions from Dulong and Petit's Law.**—Denoting the atomic weight by W and the specific heat by s, Dulong and Petit's law states that 6 s = W s. Thus if s be known, an approximate value of W is determinate. In the determination of the atomic weight of an element two factors must be considered: (1) its equivalent weight, i.e. the amount which is equivalent to one part of hydrogen; and (2) a factor which denotes the number of atoms of hydrogen which combines with or is equivalent to one atom of the particular element. This factor is termed the valency.

The equivalent weight is capable of fairly ready determination, but the settlement of the second factor is somewhat more complex, and its determination usually has to be made by means of the method of specific heats. A simple example: 38 parts of indium combine with 35.4 parts of chlorine; hence, if the formula of the chloride be InCl, InCl₂ or InCl₃, indium has the atomic weights 38, 76 or 114. The specific heat of indium is 0.057; and the atomic heats corresponding to the atomic weights 38, 76 and 114 are 3.2, 4.3, 6.5. Dulong and Petit's law thus points to the value 114, which is also supported by the position occupied by this element in the periodic classification. C. Winkler decided the atomic weight of germanium by similar reasoning.

**Boiling-Point and Composition.**—From the relation between the constant critical constants Pᵣ, Vᵣ/Tᵣ = 1/3 R or Tᵣ/Pᵣ = 3.7 Vᵣ/R, and since Vᵣ is proportional to the volume at absolute zero, the ratio Tᵣ/Pᵣ should exhibit additive relations. This ratio, termed by Guye the critical coefficient, has the following approximate values:

<table>
<thead>
<tr>
<th>C. H. Cl.</th>
<th>0̀-0̀</th>
<th>O. N.</th>
<th>N.</th>
<th>P. Double Triple</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.35</td>
<td>0.57</td>
<td>2.66</td>
<td>0.87</td>
<td>1.27</td>
</tr>
</tbody>
</table>

Since at the boiling-point under atmospheric pressure liquids are in corresponding states, the additive nature of the critical coefficient should also be presented by boiling-points. It may be shown theoretically that the boiling-point is proportional to the molecular volume, and, since this property is additive, the boiling-point should also be additive.

These relations have been more thoroughly tested in the case of organic compounds, and the results obtained agree in some measure with the deductions from molecular volumes. In general, isomers boil at about the same temperature, as is shown by the isomeric esters, diethyl malonate and diethyl succinate.

- Methyl octoate: 192° | Amyl butyrate: 184°
- Ethyl heptanoate: 187° | Heptyl acetate: 191°
- Propyl hexanoate: 185° | Octyl formate: 198°
- Butyl pentanoate: 185° | Nonyl formate: 200°

Equal increments in the molecule are associated with an equal rise in the boiling-point, but this increment varies in different homologous series. Thus in the normal fatty alcohols, acids, esters, nitriles and ketones, the increment per CH₂ is 19°-21°; in the aldehydes it is 25°-27°. In the aromatic compounds there is no regularity between the increments due to the introduction of methyl groups into the benzene nucleus or side chains; the normal value of 20°-21° is exhibited, however, by pyridine and its derivatives.

The relationship of the boiling-points of a compound to the boiling-points of compounds of the same type generally occasions a rise in boiling-point at about 100°. The same increase accompanies the introduction of the amino group into aromatic nuclei.

While certain additive relations hold between some homologous series, not between compounds of the same constitution, which must be referred to the constitution of the molecule. As a general rule, compounds formed with a great evolution of heat have high boiling-points, and vice versa. The introduction of negative groups into a molecule alters the boiling-point according to the number of negative groups already present. This is shown in the case of the chloroacetates:

- CH₂COOH = 118°
- CCH₂COOH = 185°
- CΗ₂COOH = 195°
- CCl₂COOH = 195°-200°

According to van 't Hoff the substitution of chlorine atoms into a methyl group occurs the following increments:

| C in CH₃ | 66° |
| Cl = CH₃ | 39° |
| Cl₂ = CH₃ | 15° |

The introduction of chlorine, however, may involve a fall in the boiling-point, as is recorded by Henry in the case of the chlorinated acetanilides:

<table>
<thead>
<tr>
<th>NC-CH₃</th>
<th>NC-CH₂Cl</th>
<th>NC-CH₂Cl₂</th>
<th>NC-CH₂Cl₃</th>
</tr>
</thead>
<tbody>
<tr>
<td>81°</td>
<td>123°</td>
<td>112°</td>
<td>83°</td>
</tr>
</tbody>
</table>

The replacement of one negative group by another is accompanied by a change in the boiling-point, which is independent of the compound in the first and the second, and only conditioned by the nature of the replaced and replacing group. Thus in the above table replace chlorine with increments of about 22° and 50° respectively.

A factor of considerable importance in determining boiling-points is the isomery of the molecule. Referring to the esters of fatty acids, previously mentioned, it is seen that the highest boiling-points belong to methyl octoate and octyl formate, the least symmetrical, while the minimum belongs to amyl butyrate, the most symmetrical. The isomeric pentanes also exhibit a similar relation: (CH₃)₂C₂=CH₂ = 105°, (CH₃)₂C₂=CH₂ = 110°, (CH₃)₃C = 118°. For a similar reason secondary alcohols boil at a lower temperature than the corresponding primary, the difference being about 19°. A. E. Earp (Phil. Mag., 1893, 5, p. 458) has shown that, while an increase in molecular weight generally accompanied with a rise in the boiling-point, yet the symmetry of the resulting molecule may exert a similar effect that the final result is a diminution in the boiling-point. The series H₂S = 61°, CH₃SH = 21°, (CH₃)₂S = 41° shows in the formula 

\[ \text{Temperature} = \text{Absolute Value} + \text{Additive Value} \]

The lowest melting-point is presented by methyl alcohol (67°) and methyl ether (47°). Among the aromatic di-substitution derivatives the ortho compounds have the highest boiling-point, and the meta boiling-point at a higher, and about the same temperature as the para compounds. Of the tri-derivatives the symmetrical compounds boil at the lowest temperature, the asymmetric next, and the vicinal at the highest.

An ethylene or double carbon union in the aliphatic hydrocarbons has, apparently, the same effect on the boiling-point as two hydrogen atoms. Thus C₂H₄Cl₂, C₂H₅Cl₂, C₂H₅CH₂Cl, and C₂H₅CH₂CH₂Cl, all boil about 19.5° higher than the corresponding propyl compound.

Certain regularities attend the corresponding property of the melting-point. A rule applicable to organic compounds, due to Adolf v. Baeyer and supported by F. S. Kipping (Jour. Chem. Soc., 1893, 63, p. 465), states that the melting-point of any odd member of a homologous series is lower than the melting-point of the even member containing one carbon atom less. This is true of the fatty acid series, and the corresponding ketones and alcohols, and also of the succinic acid series. Other regularities exist, but generally with many exceptions. It is to be noted that although the relation of melting-point with constitution has not been developed to an extent as the chemical significance of other physical properties, the melting-point is the most valuable test of the purity of a substance, a circumstance due in a large measure to the fact that impurities always tend to lower the melting-point.

**Heat of Combustion and Constitution.**—In the article Thermochemistry a general account of heats of formation of chemical compounds is given, and it is there shown that this constant measures the stability of the compound. In organic chemistry it is more customary to deal with the "heat of combustion," i.e. the heat evolved when an organic compound is completely burned in oxygen; the heat of formation is deduced from the fact that it is equal to the heats of formation of the products of combustion less the observed heat of combustion. The researches of Julius Thomsen and others have shown that in many cases definite conclusions regarding constitution can be drawn from quantitative measurements of the heats of combustion; and in this article a summary of the chief results will be given.

The identity of the four valencies of the carbon atom follows from the fact that the heats of combustion of methane, propane, trimethyl methane, and tetramethyl methane, have a constant difference in the order given, viz. 156 calories; this means
that the replacement of a hydrogen atom by a methyl group is attended by a constant increase in the heat of combustion. The same difference attends the introduction of the methyl group into many classes of compounds, for example, the paraffins, olefines, acetylenes, aldehydes, ketones, acids, and esters, while a slightly lower value (157-1) is found in the case of the halogenated compounds, nitriles, amines, acids, ethers, sulphones and nitrone compounds. It therefore appears that the difference between the heats of combustion of two adjacent members of a series of homologous compounds, as far as this constant is concerned, and that this constant has two average values, viz. 158-6 and 157-1.

An important connexion between heats of combustion and constitution is found in the investigation of the effect of single, double, and triple valencies on the combustion of carbon monoxide and dioxide. If twelve grammes of amorphous carbon be burnt to carbon dioxide under constant volume, the heat evolved (66-96 cal.) does not measure the entire thermal effect, but the difference between this heat and the heat of combustion of the carbon monoxide alone decides the heat of combustion of the carbon atoms. If the number of atoms in the carbon molecule be denoted by n, and the heat required to split off each atom from the molecule by d, then the total heat required to break down a carbon molecule completely into carbon atoms is: 

\[ H = 12d - nd. \]

The value of d can be evaluated by considering the combustion of amorphous carbon to carbon monoxide and carbon dioxide. In the first case the thermal effect of 58-58 calories actually observed on cooling, could be increased by 2d to allow for the heat evolved on splitting off two gramme-atoms of carbon; in the second case the thermal effect of 96-96 must be increased by d as above. Now in both cases one gramme-molecule of oxygen is decomposed, and the two or twelve formed molecules of water contain all the valencies. It follows that the thermal effects stated above must be equal, i.e., 58-58 + 2d = 96-96 + d, and therefore \( d = 38-38 \) cal. The absolute heat of combustion of a carbon atom is therefore 135-34 calories, and the heat of combustion of carbon alone 700-28 calories.

Consider now the combustion of a hydrocarbon of the general formula \( \text{C}_n\text{H}_m \). We assume that each carbon atom and each hydrogen atom contributes equally to the thermal effect. If \( a \) be the heat of combustion of this compound, then by the law of heat of combustion, the thermal effect may be expressed as \( H' = na + 2m-2 \), where \( A \) is the heat required to break the molecule into its constituent atoms. If the hydrocarbon be saturated, i.e., only contain single carbon linkages, then the number of such linkages is \( 2n-2 \), and if the thermal effect of such a linkage be equal to \( 2n-2 \), then the term obviously equals \( 2n-2 \). The value of \( H' \) then becomes \( H = na + 2m - (2n-2)X \) or \( n + m \), where \( n \) and \( m \) are constants. Let double bonds be present, in number \( p \), and let the energy due to such a bond have a heat of 96-96, then the total heat of combustion becomes \( H = n + m - 96-96 \), \( Z \) and \( X \) is the equation for \( H \) becomes

\[ H = n + m - 96-96 \times P(X-Y) + 2x2X - Y \]

This is the general equation for calculating the heat of combustion of a hydrocarbon containing four or more constant valencies, two of these may be calculated from the heats of combustion of saturated hydrocarbons, and the other two from the combustion of hydrocarbons containing double and triple linkages. By experiment it is found that the effect of a double bond is greater than the effect of two single bonds, while a triple bond has a much smaller effect than three single bonds. J. Thomsen deduces the actual values of \( X, Y, Z \) to be 14-71, 13-27 and zero; the last value he considers to be in agreement. It is interesting that the effect of the halogen atoms are

\[ H = 15-13 \text{ calories,} \]

bromine: \( \gamma = 7-8 \text{ calories,} \]

iodine: \( -4-25 \text{ calories.} \)

It is remarkable that the position of the halogen in the molecule has no effect on the heat of formation; for example, chloropropylene and allylchlorofluor, and also ethylene dichloride and ethylidene dichloride, have equal heats of formation. The theoretical effect of the ether group has an average value of 34-31 calories. This value does not hold in the case of ethylene oxide if we assign to it the formula \( \text{H}_2\text{C}-\text{O}-\text{CH}_2 \), but if the formula \( \text{H}_2\text{O}-\text{CH}_2 \) (which assumes the presence of two free hydroxyl groups) be accepted, the calculated and observed heats of formation are in agreement.

The combination of nitrogen with carbon may result in the formation of nitrates, cyanates, or primary, secondary or tertiary nitro compounds. Kekule deduced that a single bond between a carbon atom and a nitrogen gramme-atom corresponds to a thermal effect of 2-77 calories, a double bond to 5-44, and a treble bond to 8-31. From this he infers that cyanogen is \( \text{C} = \text{N}-\text{N} : \text{C} = \text{N} \) and not \( \text{C} = \text{N} - \text{N} : \text{C} = \text{N} \); that hydrazoic acid is \( \text{N} : \text{N} = \text{N} : \text{N} \). In the case of the amines he decides in favor of the formula

\[ \text{H}_2\text{C} = \text{N} - \text{H}_2 \]

\[ \text{H}_2\text{C} > \text{N} - \text{H}_2 \]

\[ \text{H}_2\text{C} = \text{N} - \text{H}_2 \]

primary, secondary, tertiary.

These involve pentavalent nitrogen. These formulæ, however, only apply to aliphatic amines; the results obtained in the aromatic series are in accordance with the usual formulæ.

**Optical Relations.**

Refraction and Composition.—Reference should be made to the article REFRACTION for the general discussion of the phenomenon known as the refraction of light. It is there shown that every substance, transparent to light, has a definite refractive index, which is the ratio of the velocity of light in vacuo to its velocity in the medium to which the refractive index refers. The refractive index of any substance varies with (1) the wave-length of the light; (2) with temperature; and (3) with the state of aggregation. The first cause of variation may be at present ignored; its significance will become apparent when we consider dispersion (vide infra). The second and third causes, however, are of greater importance, since they are associated with the molecular condition of the substance; hence, it is obvious that it is only from some function of the refractive index which is independent of temperature variations and changes of state (i.e., it must remain constant for the same substance at any temperature and in any form) that quantitative relations between refraactivity and chemical composition can be derived.

The pioneer work in this field, now frequently denominated "spectro-chemistry," was done by Sir Isaac Newton, who, from theoretical considerations based on his corpuscular theory of light, determined the function \((n^2-1) \), where \( n \) is the refractive index, to be the expression for the refractive power; dividing this expression by the density \((d \), he obtained \((n^2-1)/d \), which he named the "absolute refractive power." To P. S. Laplace is due the theoretical proof that this function is independent of temperature and pressure, and apparent experimental confirmation was provided by Biot and Arago's, and by Dulong's observations on gases and vapours. The theoretical basis upon which this formula was devised (the corpuscular theory) was shattered early in the 19th century, and in its place there arose the modern wave theory which theoretically invalidates Newton's formula. The question of the dependence of refractive index on temperature was investigated in 1838 by J. H. Gladstone and the Rev. T. P. Dale; the more simple formula \((n-1)/d \), which remained constant for gases and vapours, but exhibited slight discrepancies when liquids were examined over a wide range of temperature, being adopted. The subject was next taken up by H. Landsldt, who, from an immense number of observations, supported in a general way the formula of Gladstone and Dale. He introduced the idea of comparing the refraactivity of equimolecular quantities of different substances by multiplying the function \((n-1)/d \) by the molecular weight \((M) \) of the substance, and investigated the relations of chemical grouping to refraactivity. Although establishing certain general relations between atomic and molecular refraactivities, the results were somewhat vitiated by the inadequacy of the empirical function which he employed, since it was by no means a constant which depended only on the actual composition of the substance and was independent of its physical condition. A more accurate expression \((n^2-1)/(n^2+2) \) was
suggested in 1886 independently and almost simultaneously by L. V. Lorenz of Copenhagen and H. A. Lorentz of Leiden, from considerations based on the Clausius-Mossotti theory of dielectrics. Assuming that the molecules are spherical, R. E. Clausius and O. F. Mossotti found a relation between the dielectric constant and the space actually occupied by the molecules, viz. \( K = (1 + \frac{2a}{a-1}) \), or \( a = (K-1)/(K+2) \), where \( K \) is the dielectric constant and \( a \) the fraction of the total volume actually occupied by matter. According to the electromagnetic theory of light \( K = N^2 \), where \( N \) is the refractive index for rays of infinite wave-length. Making this substitution, and dividing by \( d \), the density of the substance, we obtain \( a/d = (N^2-1)/(N^2+2) \). Since \( a/d \) is the real specific volume of the molecule, it is therefore a constant; hence \( (N^2-1)/(N^2+2) \) is also a constant and is independent of all changes of temperature, pressure, and of the state of aggregation. To determine \( N \) recourse must be made to Cauchy’s formula of dispersion (p. 9), \( \pi = A + B N^2 + C N^4 + \cdots \), from which, by extrapolation, \( \lambda \) becoming infinite, we obtain \( N = \lambda \). In the case of substances possessing anomalous dispersion, the direct measurement of the refractive index for Hertzian waves of very long wave-length may be employed.

It is found experimentally that the Lorenz and Lorentz function holds fairly well, and better than the Gladstone and Dale formula. This is shown by the following observations of Rühmann on water, the light used being the D line of the spectrum:

<table>
<thead>
<tr>
<th>( d )</th>
<th>( n^2-1/d )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.3335</td>
</tr>
<tr>
<td>10</td>
<td>0.3335</td>
</tr>
<tr>
<td>20</td>

<td>0.3321</td>
</tr>
<tr>
<td>40</td>
<td>0.3323</td>
</tr>
<tr>
<td>50</td>
<td>0.3321</td>
</tr>
</tbody>
</table>

Eykman’s observations also support the approximate constancy of the Lorenz-Lorentz formula over wide temperature differences, but in some cases the deviation exceeds the errors of observation. The values are for the H\(_a\) line:

<table>
<thead>
<tr>
<th>Substance</th>
<th>Temp.</th>
<th>( n^2-1/d )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Isosafrol, C(<em>8)H(</em>{12})O(_2)</td>

</tr>
<tr>
<td>Quinoline, C(<em>8)H(</em>{11})N</td>
<td>12.5°</td>
<td>0.3175</td>
</tr>
</tbody>
</table>

The empirical formula \( (n^2-1)/(n^2+2)d \) apparently gives more constant values with change of temperature than the Lorenz-Lorentz form. The superiority of the Lorenz-Lorentz formula over the Gladstone and Dale formula for changes of state is shown by the following observations of Brüll (Zeit. f. physik. Chem., 1891, 71, p. 4). The values are for the D line:

Dispersion and Composition.—In the preceding section we have seen that substances possess a definite molecular (or atomic) refractive for light of particular wave-length; the difference between the refractive index of two substances is known as the molecular or atomic dispersion. Since molecular refractivities are independent of temperature and of the state of aggregation, it follows that molecular dispersions must be independent of these conditions; and hence quantitative measurements should give an indication as to the chemical composition of substances. This subject has been principally investigated by Brühl; he found that molecular dispersions of liquids and gases were independent of temperature, and fairly independent of the state of aggregation, but that no simple connection exists between atomic refractivities and dispersions (see following table). He also showed how changes in constitution effect changes in dispersions to a far greater extent than they did refractivities; thus, the latter atomic dispersion of carbon is 0.09, the dispersions due to a double and treble linkage is 0.23 and 0.19 respectively.

Colour and Constitution.—In this article a summary of the theories which have been promoted in order to connect the colour of organic compounds with their constitution will be given, and the reader is referred to the article COLOUR for the physical explanation of this property, and to VISIBILITY for the physiological and psychological bearings. A clear direction must be given between colour and the property of dyeing; all coloured substances are not dyes, and it is shown in the article DYEING that the property of entering into chemical or physical combination with fibres involves properties other than those essential to colour. At the same time, however, all dyestuffs are coloured substances.

A survey of coloured substances led O. N. Witt in 1876 to formulate his "chromophore-auxochrome" theory. On this theory colour is regarded as due to the presence of a "chromophore" group having power to an "auxochrome"; the latter by itself cannot produce colour or dyeing power, but it is only active in the presence of a chromophore, when it intensifies the colour and colours the property of dyeing. The principal chromophores are the azo, \( N = N = \), azoxy, \( = NO, \) nitro, \( = NO, \) nitroso, \( = NO, \) and carbonyl, \( = CO \) groups. The azo-group is particularly active, and is used in the formation of dyes being coloured. The simplest aliphatic compounds, such as dioxo-methane, dioxo-ethane, and azo-formic acid, are yellow; the diazide of the latter acid is orange-red. Of the aromatic compounds azo-benzene is bright orange-red, and azo-naphthaleins form reds or small steel-blue prisms. The azo-group, however, has little or no colouring effect when present in a

Additive relations undoubtedly exist, but many discrepancies occur which may be assigned, as in the case of molecular volumes, to differences in constitution. Atomic refractions may be obtained
CHEMISTRY

ring system, such as in cinnoline, phthalazine and tolazone. The nitro group has a very important action mainly on the readiness with which it can be introduced into the molecule, but its effect is much less than that of the azo group. The colour produced is generally a greenish shade, the intensity of the green being increased if the nitro group is in an ethylenic position, e.g. in acridines and their derivatives. In the azo group itself, the aggregative effect is intensified with an increase in the number of groups; compare, for example, mono-, di- and tri-nitrobenzene. The nitroso group is less important. The colour produced is generally of a greenish shade, but it is more intense if the nitroso group is in an ethylenic position, e.g. in acridines and their derivatives. When crystalline, it is colourless, and dimittosorcesolin has been employed as a dyestuff under the names “solid green” and “chlorine.” The carbonyl group by itself does not produce colour, but when two or more adjacent groups occur in the molecule, as in the a-ketones (such as di-acetyl and benzil), a yellow colour is produced. It also acts as a chromogenic centre when double bonds or ethylenic linkages are present, as in fluorescein ketone or fluorourine. A more complex chromophoric group is the triple ethylenic group \(\text{C} = \text{C} = \text{C}\), the introduction of which was rendered necessary by the discovery of certain coloured hydrocarbons. As a general rule, hydrocarbons are colourless; the exceptions include the golden yellow acenaphthylene, the red biphenylene-ethylenes, and the derivatives of fulvone \(\text{CH}_2 : \text{CH} > \text{CH}_2\), which have been discussed by J. Thiele (Ber., 1900, 33, p. 660). This grouping is not always colour-producing, since diphenyl is colourless.

The most important auxochromes are the hydroxyl (\(-\text{OH}\)) and amino \((\text{NH}_2)\) groups. According to the modern theory of the chromatic action, the introduction of a group into the molecule is accompanied by some strain, and the alteration in the colour produced is connected with the magnitude of the strain. The amino group is more powerful than the hydroxyl, and the substituents of the former are more powerful still; the repeated substitution of hydroxyl groups sometimes causes an intensification and sometimes a diminution of colour.

We may here notice an empirical rule formulated by Nieszka in 1879:—the simplest colouring substances are in the greenish-yellow and yellow, and with increasing molecular weight the colour passes into orange, red, violet, blue and green. This rule, however, is by no means perfect. Examination of the absorption spectra of coloured compounds shows that the coloured group gives rise to definite bands in one direction, and other groupings in the other. If the bands be displaced towards the violet, involving a regression through the colours mentioned above, the group is said to be “hypochrome,” or to give “red” light. This occurs when the molecules are large, for example, an aromatic system.

The phenomenon of the salt formation of coloured and colourless substances is important. The chromophoric groups are mostly strongly acid or basic; on the other hand, the auxochromes are strong acid or basic and form salts very readily. Notable differences attend the neutralization of the chromophoric and auxochromic groups. With basic substances, the chromophoric combination is salt formation; the auxochromes are generally combined by a double action; auxochromic combination, on the other hand, with a lessening.

Examples of the first case are found amongst the colourless acids and quinolines which give coloured salts; of the second case, the colourohelic acids and sulphate of the deep yellow \(\alpha\)-aminobenzophenone. With acid substances, the combination with “colourless” metals, i.e. metals producing colourless salts with acids, is attended by colour changes contrary to those given above, and the auxochromes are sometimes accompanied by a deepening, and chromophoric by a lessening of the tint.

Mention may be made of the phenomenon of halochromism, the name given to the power of colourless or faintly-coloured substances of combining with acids to form the corresponding salt without any necessary production of a chromophoric group. The researches of Adolf von Baeyer and Villiger, Kehrmann, Kaufmann and others, show that this property is possessed by very many and varied substances. In many cases it may be connected with basic oxygen, and in some cases with basic nitrogen. For example, the passage of a nitroglycerin salt into tetravalent oxygen. It seems that intermolecular change also occurs, but further research is necessary before a sound theory can be stated.

Quinone Theory of Colour.—A theory of colour in opposition to the Witt theory was proposed by Henry Armstrong in 1888 and 1892. This assumed that all coloured substances were derivatives of ortho- or para-quinone (see Quinones), and although at the time of its promotion little practical proof was given, yet the theory found wide acceptance on account of the researches of many other chemists. It follows on this theory that all coloured substances contain either of the groupings

\[
\text{C}_6\text{H}_4\text{NO}_2
\]

or

\[
\text{C}_6\text{H}_4\text{N}_2\text{O}_2
\]

the former being a para-quinonoid, the latter an ortho-quinonoid. While very many colourless substances must obviously contain this grouping, yet in many cases it is necessary to assume a simple intermolecular change, while in others a more complex rearrangement of bonds is necessary. Quinones, which is light yellow in colour, is the simplest coloured substance on this theory. Hydrocarbons of similar structure have been prepared by Thiele, for example, the orange-yellow tetraphenyl-para-xylene, which is obtained by boiling the bromide \(\text{C}_6\text{H}_4\text{Br} - \text{C}_6\text{H}_4\text{Br}\) with benzene and molecular silver. The quinonoid structure of many coloured derivatives has been proved experimentally, as, for example, by Hewitt for the benzene-azo-phenols, and Hantzsch for triaminotriphenyl methane and acridine derivatives; but, at the same time, many substances cannot be so explained. A notable example is provided by the yellow which results by the condensation of phthalic anhydride with phenols. In the free state these substances are colourless, and were assumed to have the formula shown in 1. Solution in dilute alkali was supposed to be accompanied by the rupture of the lactone ring with the formation of the quinonoid salt shown in 2.

The proof of this was left for Hantzsch, who traced a connexion with the nitrolic acids of V. Meyer, which are formed when nitric acid acts on primary aromatic nitro compounds. Meyer formulated these compounds as nitrooximes or nitro-isnitroso derivatives, viz. R-C(NO)(N=0), Hantzsch explains the transformation of the colourless acid into red salts, which on standing yield more stable, colourless salts, by the following scheme:

Where R = COCH_3, CH_3COCH_3, or CH_3COOCH_3, and where R may be H, CH_3 or C_2H_5.

Other colourless substances are derived from the three foregoing substances. The colourless, stable, Colourless, labile. Colourless, stable. He has also shown that the nitrophenols yield, in addition to the colourless true nitrophenol ethers, an isomeric series of colourless unstable quinonoid \(\text{O} = \text{C} = \text{N} = \text{N}\)-ethers, which have practically the same colour and yield the same absorption spectra as the colourless metallic salts. He suggests that the term “quinone” should be abandoned, and replaced by the Umbelliferone, since this term implies some intermolecular rearrangement, and does not connote simply benzenoid compounds as does “quinone.” H. von Liebig (Ann., 1908, 356, p. 129), from a very complete discussion of the triphenylmethane derivatives, concluded that the grouping \(\text{A} \cdot \text{A} \cdot \text{A}\) was the only true organic chromophore, colour production, however, requiring another condition, usually the closing of a ring.

The views as to the question of colour and constitution may be summarized as follows:—(1) The quinone theory (Armstrong, Goemger, R. Meyer) regards all coloured substances as having a quinonoid structure. (2) The chromophoric-quinone theory (Kaufmann) regards colour as due to the entry of an “auxochrome” into a “chromophoric” molecule. (3) If a bicolourous compound gives a coloured one on solution or b
salt-formation, the production of colour may be explained as a particular form of ionization (Baeyer), or by a molecular re-arrangement (Hantzsch). A dynamical theory of E. C. C. Baly regards colour as due to "isotropism" or an oscillation between the residual affinities of adjacent atoms composing the molecule.

Fluorescence and Constitution.—The physical investigation of the phenomenon named fluorescence—the property of transforming incident light into light of different refrangibility—is treated in the article FLUORESCENCE. Researches in synthetic organic chemistry have shown that this property of fluorescence is common to an immense number of substances, and theories have been proposed whose purpose is to connect the property with constitution.

In 1897 Richard Meyer (Zeit. physik. Chem. 24, p. 468) submitted the view that fluorescence was due to the presence of certain "fluorescent groups" generated in the pyrone ring and its congeners, the central rings in anthracene and acridine derivatives, and the paradiazole ring in safranines. A novel theory, proposed by J. T. Hewitt in 1900 (Zeit. physik. Chem. 34, p. 1; B.A. Rep. 1903, p. 629, and later papers in the Journ. Chem. Soc.), regards the property as occasioned by internal vibrations within the molecular condition set up by a symmetrical double tautomerism, light of one wave-length being absorbed by one form, and emitted with a different wave-length by the other. This theory may be represented in the case of acridine and fluorenic acid as

\[
\text{C}_6\text{H}_4\text{CH}=\text{O} + \text{H}_2\text{O} \rightarrow \text{C}_6\text{H}_4\text{CHOH} + \text{H}_2\text{O}
\]

This theory brings the property of fluorescence into relation with that of colour; the forms which cause fluorescence being the coloured modifications: ortho-quinonoid in the case of acridine, paraquinonoid in the case of fluorenic acid. H. Kauffmann (Ber., 1900, 33, p. 1231; 1903, 36, p. 304; 1905, 38, p. 730), suggested that the property is due to the presence of at least two groups. The first group, named the "luminophore," is such that when excited by suitable aetheric vibrations emits radiant energy; the second group, the "fluorogen," is that of the substance which in some way or other can cause the fluorescence. This theory explains the fluorescence of anthranilic acid (\(\text{C}_6\text{H}_4\text{CHOHCOOH}\)), by regarding the aniline residue as the luminophore, and the carboxyl group as the fluorogen. According to the introduction of the latter, the non-fluorescent aniline molecule involves the production of a fluorescent substance. Although the theories of Meyer and Hewitt do not explain (in their present form) the behaviour of anilinic acid, yet Hewitt has devised a hypothesis explained in the case of the above substances in which a double symmetrical tautomerism is possible. This tautomerism may be of twofold nature:—(1) it may involve the mere oscillation of linkages, as in acridine; or (2) it may involve the oscillation of atoms, as in fluorescein. A theory of the physical nature, based primarily upon Sir J. J. Thomson's theory of corpuscles, has been proposed by J. de Kowalski (Compt. rend. 1907, 144, p. 266). We may notice that ethyl oxalosuccinimide is the first case of a fluorescent aliphatic compound (see below), in which two factors are involved.

Capillarity and Surface Tension.—Reference should be made to the article CAPILLARY ACTION for the general discussion of this phenomenon of liquids. It is there shown that the surface tension of a liquid may be calculated from its rise in a capillary tube by the formula 

\[
\gamma = \frac{2
\rho g h}{r} \text{ergs per square centimetre,}
\]

where \(\gamma\) is the tension per square centimetre, \(r\) the radius of the tube, \(h\) the height of the liquid column, and \(s\) the difference between the densities of the liquid and its vapour. At the critical point liquid and vapour become identical, and, consequently, as was pointed out by Frankenstein in 1841, the surface tension is zero at the critical temperature.

Mendeleff endeavoured to obtain a connexion between surface energy and constitution; more successful were the investigations of E. F. du Bois and D. F. du Bois and their collaborator, T. E. Brache, who, by means of the capillary rise of liquids, obtained a coefficient of surface tension by the formula

\[
\gamma = \frac{2
\rho g (s + V)}{r} \text{ergs per square centimetre,}
\]

where \(\gamma\) is the surface tension, \(s\) the surface tension of the saturated vapour, and \(V\) the molecular volume of that saturated vapour. To these figures to a common standard, so that the volumes shall contain equal numbers of molecules, the notion of molecular volumes is introduced, the arbitrary values of the crystallographic axes (\(a, b, c\)) being replaced by the topic parameters\(^1\) (\(\chi, \psi, \omega\), which are such that, combined with the axial angles, they enclose volumes which contain equal numbers of molecules. The atomic parameters \(a, b, c\) then can be expressed in terms of the elements of the crystals (the axial ratios and angles), the density, and the molecular weight (see Groth, Physikalische Kristallographie, or Chemical Crystallography).

This was done simultaneously in 1894 by W. Muthmann and A. E. H. Tutten, the latter receiving the idea from F. Becke (see Journ. Chem. Soc., 1886, 69, p. 507; 1905, 87, p. 1183).
Polymorphism.—On the theory that crystal form and structure are the result of the equilibrium between the atoms and molecules composing the crystals, it is probable, a priori, that the same substance may possess different equilibria, and therefore different crystal forms. Clearly this phenomenon is termed polymorphism; however, it is necessary to examine closely the different crystal modifications in order to determine whether they are really of different symmetry, or whether twinning has occurred. In the article Crystallography the nature and behaviour of twinned crystals receives full treatment; here it is sufficient to say that when the planes and axes of twinning are planes and axes of symmetry, a crystal would exhibit higher symmetry (but remain in the same crystal system) than the primary crystal; and, also, if a crystal approximates in its axial constants to a higher system, mimetic twinning would increase the approximation, and the crystal would be pseudo-symmetric.

In general, polycentric and polyphasic modifications demonstrate the same phenomenon as when submitted to variations in either temperature or pressure, or both. The criterion whether a pseudo-symmetric form is a true polymorph or not consists in the determination of the scalar properties (e.g., density, specific heat, &c.) of the original and modified modification; a change being in general recognized only when polymorphism exists. Hence temperature usually suffices to determine this, though in certain cases a variation in pressure is necessary, for instance, sodium magnesium uranyl acetate, NaMg(UO)₃(C₂H₃O₂)₉H₂O shows no change in density unless the observations are conducted under a considerable pressure. Although many pseudo-symmetric twins are transformable into the simpler form, yet, in some cases, a true polycentric result, the change being indicated, as before, by alterations in scalar (as well as vector) properties.

For example, boracite forms pseudo-cubic crystals which become truly cubic at 265°, with a distinct change in density; leucite behaves similarly at about 500°. Again, the pyroxenes, RSbrine twinned so as to become pseudo-rhombohedral; (2) rhombohedral, resulting from the pseudo-rhombohedral structure of (1) becoming ultramicroscopic; and (3) trigonal, distinctly different from (1) and (2); (1) and (2) are polycentric modifications, while (3) and the pair (1) and (2) are polyphasic.

While polycentricity is solely conditioned by the manner in which the mimetic twin is built up from the simple crystals, there being no change in the scalar properties, and the vector properties being calculable from the nature of the twinning, in the case of polymorphism entirely different structures present themselves, both scalar and vector properties being altered; and, in the present state of our knowledge, it is impossible to forestall the conjunction of a polycentric modification. We may conclude that in polyphasic substances the substance occurs in different phases (or molecular aggregations), and the equilibrium between these phases follows definite laws, being dependent upon temperature and pressure, and amenable to thermodynamic treatment.

The transformation of polyphasic substances presents certain analogies to the solidification of a liquid. Liquids may be cooled and flow their freezing-point without solidification; the metastable (after W. Ostwald) form so obtained becomes immediately solidified on the introduction of a particle of the solid modification; and supersaturated solutions behave in a similar manner. At the same time there may be conditions of temperature and pressure at which polyphases may exist side by side.

The above may be illustrated by considering the equilibrium between rhombic and monoclinic sulphur. The former, which is deposited from solutions, is transformed into monoclinic sulphur at about 96°, but with great care it is possible to overheat it and even to fuse it (at 135°) without effecting the transformation. Monoclinic sulphur, obtained by crystallizing fused sulphur, melts at 119-5°, and admits of undercooling even to ordinary temperatures, but contact with a fragment of the rhombic modification spontaneously brings about the transformation. From Reicher's determination the exact transition point is 95-6°; it rises with increasing pressure about 0-4° for one atmosphere; the density of the rhombic form is greater than that of the monoclinic. The equilibria of these modifications may be readily represented on a pressure-temperature diagram. H.O.T, OP (fig. 6), be the axes of temperature and pressure, and A corresponds to the transition point (95-6°) of rhombic sulphur, we may follow out the line AB which shows the elevation of the transition point with increasing pressure. The over-heating curve of rhombic sulphur extends along the curve AC, where C is the melting-point of monoclinic sulphur. The line DE representing the equilibrium between monoclinic and liquid sulphur is thermodynamically calculable; the point B is found to correspond to 135° and 400 atmospheres. From D, a curve of equilibrium (BD) between rhombic and liquid sulphur proceeds; and from C (along CE) the curve of equilibrium between monoclinic sulphur and liquid and vapour. Of special interest is the curve BD; along this line liquid and rhombic sulphur are in equilibrium, which means that at above 135° and 400 atmospheres the rhombic (and not the monoclinic) variety would separate from liquid sulphur.

Mercure iodide also exhibits a polymorphous nature. When precipitated from solutions it forms red tetragonal crystals, which, on careful heating, give yellow monoclinic crystals; the same is also the case with the red reacts among other binary compounds. As, however, being formed by lifting, the transformation, however, being readily induced by a trace of the red modification, or by friction. The density and specific heat of the tetragonal form are greater than those of the yellow.

Hexachloroethane is trimorphous, forming rhombic, trigonal, and cubic crystals; the successive changes occur at about 44° and 71°, and are attended by a decrease in density.

Tetromorphism is exhibited by ammonium nitrate. According to O. Lehmann it melts at 168° (or at a slightly lower temperature in its water of crystallization) and on cooling forms optically isotropic crystals; at 125° the mass becomes doubly refracting, and from a solution rhombohedral (optically uniaxial) crystals are deposited; and at 32° other rhombohedral forms are obtained, identical with the product obtained by crystallizing at ordinary temperatures. The reverse series of transformations occurs when this final modification is heated; the prismatic form (Zeit. f. Krist., 14, p. 78) is determined, and the specific heats of these modifications. The first and third transformations (reckoned in order with increasing temperature of the transition point) are attended by an increase in volume and also obtained by crystallization of the same direction, increasing to 82-8°, then diminishing up to 125°, and then increasing from this temperature upwards.

The physical conditions under which polymorphous modifications are prepared control the form which the substance assumes. We have already seen that temperature and pressure exercise considerable influence in this direction. In the case of separation from solutions, either by crystallization or by precipitation by double decomposition, the temperature, the concentration of the solution, and the nature of the ions may modify the form obtained. In the case of sodium dihydrogen phosphate, NaH₂PO₄.H₂O, a stable rhombic form is obtained from warm solutions, while a different, unstable, rhombic form is obtained from cold solutions. Calcium carbonate separates as hexagonal calcite from cold solutions (below 35°), and as rhombic aragonite from solutions at higher temperatures; lead and strontium carbonates, however, decrease the separation of aragonite at lower temperatures.

From supersaturated solutions the form unstable at the temperature of the experiment is, as a rule, separated, especially on the introduction of a crystal of the unstable form; and, in some cases, similar inoculation of the fused substance is attended by the same result. Different modifications may separate and exist side by side at one and the same time from a solution; e.g., telluric acid forms cubic and monoclinic crystals from a hot nitric acid solution, and ammonium fluosilicate gives cubic and hexagonal forms from aqueous solutions between 6° and 13°.

A comparison of the transformation of polymorphs leads to a twofold classification: (1) polymorphs directly convertible in a reversible manner—termed "enantiotropic" by O. Lehmann and (2) polymorphs in which the transformation proceeds in one direction only—termed "monotropic." In the first class
are included sulphur and ammonium nitrate; monotropy is exhibited by aragonite and calcite.

It is doubtful whether any general conclusions can yet be drawn as to the relations between crystal structure and scalar properties and the relative stability of polymorphs. As a general rule the modification stable at higher temperatures possesses a lower density; but this is by no means always the case, since the converse is true for antimonious and arsenious oxides, silver iodide and some other substances. Attempts to connect a change of symmetry with stability show equally a lack of generality. It is remarkable that a great many polymorphous substances assume more symmetrical forms at higher temperatures, and a possible explanation of the increase in density of such compounds as silver iodide, &c., may be sought for in the theory that the formation of a more symmetrical configuration would involve a drawing together of the molecules, and consequently an increase in density. The insufficiency of this argument, however, is shown by the data for arsenious and antimonious oxides, and also for the polymorphs of calcium carbonate, the more symmetrical polymorphs having a lower density.

**Morphology.**—Many instances have been recorded where substitution has affected a deformation in one particular direction, the crystal of homologue having been found to be exhibiting the same angles between faces situated in certain zones. The observations of Slavik (Zeit. f. Kryrst., 1902, 36, p. 268) on ammonium and the quaternary ammonium iodides, of J. A. Le Bel and A. Ries (Zeit. f. Kryst., 1902, 1904, et seq.) on the substituted ammonium chlorplatinates, and of G. Mez (ibid., 1901, 35, p. 242) on substituted uracils illustrate this point.

Ammonium iodide assumes cubic forms with perfect cubic cleavage; tetramethyl ammonium iodide is tetragonal with perfect cleavage parallel to {100} and {001}—a difference due to the lengthening of the a axes; tetraethyl ammonium iodide also assumes tetragonal forms, but does not exhibit the cleavage of the tetramethyl compound; while tetrapropyl ammonium iodide crystallizes in rhombic form. The equivalent volumes and topic parameters are tabulated:

</table>

From these figures it is obvious that the first three compounds form a morphotropic series; the equivalent volumes exhibit a regular progression of values χ and corresponding to the a axes, are regularly increased, while the value of ω, corresponding to the ε axis, remains practically unchanged. This points to the conclusion that substitution has been effected in one of the cube faces. With this therefore regard the nitrogen atoms as occupying the centres of a cubic space lattice composed of iodine atoms, between which the hydrogen atoms are distributed on the tetrahedron face normals. Coplanar substitution in four hydrogen atoms would involve the pushing apart of the iodine atoms in four horizontal directions. The magnitude of this separation would obviously depend on the magnitude of the substituent group, which may be large (in this case propyl is sufficient) as to cause unequal horizontal deformation and at the same time a change in the vertical direction.

The measure of the loss of symmetry associated with the introduction of alkyl groups depends upon the relative magnitudes of the substituent group and the rest of the molecule; and the larger the molecule, the less would be the morphotropic effect of any particular substituent. The mere retention of the same crystal form by homologous substances is not a sufficient reason for denying a morphotropic effect of the substituent group; for, in the case of certain substances crystallizing in the cubic system, although the crystal form remains unaltered, yet the structure varies. Where both the crystal form and structure are retained, the substances are said to be isomorphous.

Other substituent groups exercise morphotropic effects similar to those exhibited by the alkyl radicles; investigations have been made on halogen-, hydroxy-, and nitro-derivatives of benzene and substituted benzenes. To Jaeger is due the determination of the topic parameters of certain haloid-derivatives, and, while showing that the morphotropic effects closely resemble those occasioned by methyl, he established the important fact that, in general, the crystal form depended upon the orientation of the substituents in the benzene complex.

Benzoic acid is pseudo-tetragonal, the principal axis being remarkably long; there is no cleavage at right angles to this axis. Direct nitration gives (principally) m-nitrobenzoic acid, also pseudo-tetragonal with a much shorter principal axis. From this two chloronitrobenzoic acids [COOH-NO₂-C₆H₅, 1:3:6, and 1:3:4] may be obtained. The azoic acid (the 1:3:4) acid has nearly the same values of χ and ψ as benzoic acid, but it is increased; compared with m-nitrobenzoic acid, χ and ψ have been diminished, whereas ω is much increased; the (1:3:4) acid is more closely related to m-nitrobenzoic acid, χ and ψ being increased, ω diminished. This is borne out by the values of χ and ψ in the azoic acids also illustrate the dependence of the crystal form and structure on the orientation of the molecule.

The hydroxyl group also resembles the methyl group in its morphotropic effects, producing, in many cases, no change in symmetry but a dimensional increase in one direction. This holds for benzene and phenol, and is supported by the observations of Gossner on [1:3:5] trinitrobenzene and picric acid (1:3:5-trinitro, 2 oxybenzene); these two substances would be expected to differ from trinitrobenzene in having χ considerably greater, with χ and ψ slightly less. A similar change, in one direction only, characterizes benzoic acid and salicylic acid.

The nitro group behaves very similarly to the hydroxyl group. The effect of varying the position of the nitro group in the molecule is well marked, and conclusions may be drawn as to the orientation of the groups from a knowledge of the crystal form; a change in the symmetry of the substituent molecule being often attended by a loss in the symmetry of the crystal.

It may be generally concluded that the substitution of alkyl, nitro, hydroxyl, and halogen groups for hydrogen in a molecule occasionally producing a change of crystal structure in one definite direction, hence permitting inferences as to the configuration of the atoms composing the crystal; while the nature and degree of the alteration depends (1) upon the crystal structure of the unaltered compound; (2) on the nature of the substituting radicle; (3) on the complexity of the substituted molecule; and (4) on the orientation of the substitution derivative.

**Isomorphism.**—It has been shown that certain elements and groups exercise morphotropic effects when substituted in a compound; it may happen that the effects due to two or more groups are nearly equivalent, and consequently the resulting crystal forms are nearly identical. This phenomenon was first noticed in 1822 by E. Mitscherlich, in the case of the acid phosphate and acid arsenate of potassium, K₂H₂P(AsO₄)₃, who adopted the term isomorphism, and regarded phosphorus and arsenic as isomorphously related elements. Other isomorphously related elements and groups were soon perceived, and it has been shown that elements so related are also related chemically.

Tutton’s investigations of the morphotropic effects of the metals potassium and sodium on the crystal structure of synthetic rubidium and caesium salts, showed that the replacement of potassium by rubidium, and this metal in turn by caesium, was accompanied by progressive changes in two physical and crystallographical properties, such that the rubidium salt was always intermediate between the salts of potassium and caesium (see table: the space unit is taken as a pseudo-hexagonal prism). This fact finds a parallel in the atomic weights of these metals.

By taking appropriate differences the following facts will be observed: (1) the replacement of potassium by rubidium occasions little effect in the equivalent volume, the change being equivalent to the difference in the atomic weight of rubidium by caesium by about eleven units; (2) replacement in the same order is attended by a general increase in the three topic parameters, a greater increase being met with in the replacement of rubidium by caesium, in which position the effect of the atomic weight increase when the increase in ω is always the greatest. Now consider the effect of replacing sulphur by selenium. It will be seen that (1) the increase in equivalent volume is about 6:6; (2) all the topic parameters are increased; (3) the greatest increase is effected in the parameters χ and ψ, the former being greatly lengthened.

These observations admit of ready explanation in the following...
CHEMISTRY

The ordinary structural formula of potassium sulphate is

$$K_2SO_4$$

If the crystal structure is regarded as composed of

do three interpenetrating point systems, one consisting of sulphur atoms, the second of four times as many oxygen atoms, and the third of potassium atoms. The systems of sulphur atoms and oxygen atoms are arranged in such a way that the sulphur system is always centrally situated with respect to the other two, and the potassium system so that it would affect the vertical axis, then it is obvious that the replacement of potassium by an element of greater atomic weight would specially increase the length of $$\omega$$ (corresponding to the vertical axis), and cause a smaller increase in the horizontal parameters (x and y); moreover, the increments would advance with the atomic weight of the replacing metal. If, on the other hand, the sulphur system be replaced by a corresponding selenium system, an element of higher atomic weight, it would be expected that a slight increase would be observed in the vertical parameter, and a greater increase recorded equally in the horizontal parameters.

Muthmann (Zeit. f. Kryst., 1894), in his researches on the tetragonal potassium and ammonium dihydrogen phosphates and arsenates, found that the replacement of potassium by ammonium was attended by an increase of about six units in the molecular volume, and of phosphorus by arsenic by about 4.6 units. In the topic parameters the following changes were recorded: replacement of potassium by ammonium was attended by a considerable increase in $$\omega$$, x and y being equally, but only slightly, increased; replacement of phosphorus by arsenic was attended by a considerable increase, equally in x and y, while $$\omega$$ suffered a smaller, but not inconsiderable, increase. It is thus seen that the ordinary plane representation of the structure of compounds possesses a higher significance than could have been suggested prior to crystallographical researches.

Identity, or approximate identity, of crystal form is not in itself sufficient to establish true isomorphism. If a substance deposits itself on the faces of a crystal of another substance of similar crystal form, the substances are probably isomorphous. Such parallel-faced, termed epi-somorphs, are very common among the potassium and sodium felspars; and K. v. Hauer has investigated a number of cases in which such epismorphism have different colours, thereby clearly demonstrating this property of isomorphism. For example, epismorphs of white potash alum and violet chrome alum, of white magnesium sulphate and green nickel sulphate, and of many other pairs of salts, have been obtained.

More useful is the property of isomorphous substances of forming mixed crystals, which are strictly isomorphous with their constituents, for all variations in composition. In such crystals each component plays its own part in determining the physical properties; in other words, any physical constant of a mixed crystal can be calculated as additively composed of the constants of the two compounds.

Fig. 7 represents the specific volumes of mixtures of ammonium and potassium sulphates; the ordinates represent specific volumes, and the abscissae the percentage composition of the mixture. Fig. 8 shows the variation of the unit cell parameters of mixed crystals of potash alum and thallium alum with variation in composition.

In these two instances the component materials are alike in all proportions; but this is by no means always the case. It may happen that the crystals do not form double salts, and are only miscible in certain proportions. Two cases then arise: (1) the properties may be expressed as linear functions of the composition; or (2) similar to (1) except that different values must be assigned to the terminal values in order to provide linearity. Fig. 9 illustrates the first case: the ordinates represent specific volumes, and the abscissae denote the composition of isomorphous mixtures of ammonium and potassium dihydrogen phosphates, which mutually take one another up to the extent of 20% to form homogeneous crystals. The second case is illustrated in fig. 10. Magnesium sulphate (orthorhombic) takes up ferrous sulphate (monoclinic) to the extent of 19%, forming isomorphous orthorhombic crystals; ferrous sulphate, on the other hand, takes up magnesium sulphate to the extent of 54% to form monoclinic crystals. By plotting the specific volumes of these mixed crystals as ordinates, it is found that they fall on two lines, the upper corresponding to the orthorhombic crystals, the lower to the monoclinic. From this we may conclude that these salts are isomorphous: the upper line represents isomorphous crystals of stable orthorhombic magnesium sulphate and unstable orthorhombic ferrous sulphate, the lower line isomorphous crystals of stable monoclinic ferrous sulphate and unstable monoclinic magnesium sulphate.

An important distinction separates true mixed crystals and crystal-related double salts, for in the latter the properties are not linear functions of the properties of the components; generally there is a contraction in volume, while the refractive indices and other physical properties do not, in general, obey the additive law.

Isomorphism is most clearly discerned between elements of analogous chemical properties; and from the wide generality of such observations attempts have been made to form a classification of elements based on isomorphous replacements. The following table shows where isomorphism may be generally expected: the elements are arranged in eleven series, and the elements of any one series are subdivided (as indicated by semicolons) into groups; these groups exhibit partial isomorphism with the other groups of the same series (see W. Nernst, Theoretical Chemistry).

Series 1. Cl, Br, I, F; Mn (in permanganates).

2. S, Se; Te (in tellurides); Cr, Mn, Te (in the acids H2RO4; As, Sb (in the glances MR).)

3. As, Sb, Bi; Te (as an element); P, Vd (in salts); N, P (in organic bases).

4. K, Na, Cs, Rb, Li; Ti, Ag.

5. Li, Ba, Sr, Pb; Fe, Zn, Mn, Mg; Ni, Co, Cu, Ce, La, Dy, Er, Y, Ca; Cu, Hg, Pb; Cd, Be, In, Zn; T1, Pb.

6. Al, Fe, Cr, Mn; Ce, U (in sesquioxides).

7. Cu, Ag (when monovalent); Au.

8. Pr, Ir, Pt; Rh, Ru, Os; Al, Fe, Ni; Sn, Te.

9. C, Si, Ti, Zr, Th, Sn; Fe, Ti.

10. Ta, Nb (Nb).

11. Mo, W, Cr.

vol. i., 1900, Eng. trans.) G. K. Schmidt, Kurzes Lehrbuch der organischen Chemie; A. Berthelsen, Organische Chemie (Eng. trans.). Practical methods are treated in Lasser-Cohn, Arbeitsmethoden für organisch-chemische Laboren (4th ed., 1906-1907). Select chapters are treated in A. Lachmann, Spaltung Organische Chemie (1908); and W. Stewart, Recent Advances in Organic Chemistry (1908) and in a series of pamphlets issued since 1896 under the title Sammlung chemiker und chemisch-technischer Vorträge.

Encyclopedia of early chemistry is that of Muspratt and Watts are agreeable to date; there is a later edition of the latter by H. F. Morley and M. P. Muir, A. Ladenburg, Handwörterbuch der Chemie. A. Wurtz, Dictionnaire de chimie, and F. Selmi, Encyclopédie de chimie, are more valuable; the latter two are kept up by annual supplements.

CHEMNITZ (or KEMNITZ), MARTIN (1522-1586), German Lutheran theologian, third son of Paul Kemnitz, a cloth-worker of noble extraction, was born at Treuenbrietzen, Brandenburg, on the 6th of November 1522. Left an orphan at the age of eleven, he worked for a time at his father's trade. At Magdeburg he put him to school there (1539-1542). Having made a little money by teaching, he went (1543) to the university of Frankfurt-on-Oder; thence (1545) to that of Wittenberg. Here he heard Luther preach, but was more attracted by Melanchthon, who interested him in mathematics and astrology. Melanchthon gave him (1547) an introduction into his son-in-law, Georg Sabinus, at Königsberg, where he was tutor to some Polish youths, and rector (1548) of the Kneiphof school. He practised astrology; this recommended him to Duke Albert of Prussia, who made him his librarian (1550). He then turned to Biblical, patriotic and kindred studies. His powers were first brought out in controversy with Osiander on justification by faith. Osiander, maintaining the infusion of Christ's righteousness into the believer, impugned the Lutheran doctrine of justification; Chemnitz defended it with striking ability. As Duke Albert sided with Osiander, Chemnitz resigned the librarianship. Returning (1553) to Wittenberg, he lectured on Melanchthon's Loc i Communes, his lectures forming the basis of his own Loc i Theologic i (published posthumously, 1591), which constitute probably the best exposition of Lutheran theology as formulated and modified by Melanchthon. His lectures were thronged, and a university career of great influence lay before him, when he accepted a call to become coadjutor at Brunswick to the superintendent, Joachim Mörlin, who had known him at Königsberg. He removed to Brunswick on the 15th of December 1554, and there spent the remainder of his life, refusing subsequent offers of important offices from various Protestant princes of Germany. Zealous in the duties of his pastoral charge, he took a leading part in the theological controversy. His personal influence, and especially the period, did much to secure the strictness of doctrine and compactness of organization in the Lutheran Church. Against Crypto-Calvinists he upheld the Lutheran view of the eucharist in his Repuls ito sanae doctrinae de Vera Praesentia (1560; in German, 1561). To check the reaction towards the old religion he wrote several works of great power, especially his Theologiae Jesu Christi praecepta capit a (1562), an incisive attack on the principles of the society, and the Examen concilii Tridentini (four parts, 1565-66-72-73), his greatest work. His Corpus doctrinae Prutenicum (1567), drawn up in conjunction with Mörlin, at once acquired great authority. In the year of its publication he became superintendent of Brunswick, and in effect the director of his church throughout Lower Saxony. His tact was equal to his learning. In conjunction with Andrä and Selencker he induced the Lutherans of Saxony and Swabia to adopt the Formula Concordiae and so become Protestants. Against the views of Socinian tendency he directed his able treatise De dubius naturis in Christe (1570). Resigning office in infirm health (1584) he survived till the 8th of April 1586.

Lives of Chemnitz are numerous, e.g. by J. Gasmerus (1588), T. Presel (1862), C. G. H. Lentz (1866), H. Hachfeld (1876), A. Schmidt in J. J. Herzog's Realencyklopädie (1878), J. Kunze in A. H. Köhler's Realencyklopädie für prot. Theol. und Kirch. (1879), and by Wuste, in L. G. Schiörlin's Dict. encyclopédique de la théol. cath. (1868), gives a Roman Catholic view. (A. G.)

CHEMNITZ, a town of Germany, in the kingdom of Saxony, the capital of a governmental district, 50 m. S.W.S. of Dresden and 51 S.E. of Leipzig by rail. Pop. (1885) 110,817; (1905) 244,405. It lies 930 ft. above the sea, in a fertile plain at the foot of the Erzgebirge, watered by the river Chemnitz, an affluent of the Mulde. It is the chief manufacturing town in the kingdom, ranked next to Dresden and Hamburg in point of population, and is one of the principal commercial and industrial centres of Germany. It is well provided with railway communication, being directly connected with Berlin and with the populous and thriving towns of the Erzgebirge and Vogtland. Chemnitz is in general well built, the enormous development of its industry and commerce having of late years led to the laying out of many fine streets and to the embellishing of the town with handsome buildings. The centre is occupied by the market square, with the handsome medieval Rathaus, now superseded for municipal business by a modern building in the Post-strasse. In this square are monuments to the emperor William I., Bismarck and Moltke. The old inner town is surrounded by pleasant promenades, occupying the site of the old fortifications, and it is beyond these that industrial Chemnitz lies, girdling the old town on all sides with a thick belt of streets and factories, and ramifying far into the country. Chemnitz has eleven Protestant churches, among them the ancient Gothic church of St James, with a fine porch, and the modern churches of St Peter, St Nicholas and St Mark. There is also a separation chapel of various sects. The industry of Chemnitz has gained for the town the name of "Saxon Manchester." First in importance are its locomotive and engineering works, which give employment to some 20,000 hands in 90 factories. Next come its cotton-spinning, hosiery, textile and glove manufactures, in which a large trade is done with Great Britain and the United States. It is also the seat of considerable dyeworks, bleachers, chemical and woollen factories, and produces leather and straps, cement, small vehicles, wire-woven goods, carpets, beer and bricks. The town is well provided with technical schools for training in the various industries, including commercial, public, economic and agricultural schools, and has a chamber of commerce. There are also industrial and historical museums, and collections of painting and natural history. The local communications are maintained by an excellent electric tramway system. To the north-west of the town is the Gothic church of a former Benedictine monastery, dating from 1314-1523, with a tower of 1807. Chemnitz is a favourite tourist centre for excursions into the Erzgebirge, the chain of mountains separating Saxony from Bohemia.

Chemnitz (Kamnitz) was originally a settlement of the Sorbian Wends and became a market town in 1143. Its municipal constitution dates from the 14th century, and it soon became the most important industrial centre in the mark of Meissen. A monopoly of bleaching was granted to the town, and thus a considerable trade in woollen and linen yarns was attracted to Chemnitz; paper was made here, and in the 16th century the manufacture of cloth was very flourishing. In 1579 the Reformation was introduced, and in 1546 the Benedictine monastery, founded about 1136 by the emperor Lothair II., was dissolved. During the Thirty Years' War Chemnitz was plundered by all parties and its trade was completely ruined, but at the beginning of the 18th century it had begun to recover. Further progress in this direction was made
during the 19th century, especially after 1834 when Saxon joined the German Zollverein.

See Zoller, Geschichte der Fabrik- und Handelsstadt Chemnitz (1801) and Straumer, Die Fabrik- und Handelsstadt Chemnitz (1802).

CHEMOTAXIS (from the stem of "chemistry" and Gr. ῥήγας, arrangement), a biological term for the attraction exercised on living or growing organisms or their members by chemical substances; e.g. the attraction of the male cells of ferns or mosses by an organic acid or sugar-solution.

CHENAB (the Greek Acesines), one of the "Five rivers" of the Punjab, India. It rises in the snowy Himalayan ranges of Kashmir, enters British territory in the Sialkot district, and flows through the plains of the Punjab, forming the boundary between the Rechna and the Jech Doabs. Finally it joins the Jhelum at Trimmu.

The Chenab Colony, resulting from the great success of the Chenab Canal in irrigating the desert of the Bar, was formed out of the three adjacent districts of Gujranwala, Jhang, and Montgomery in 1892, and contained in 1901 a population of 701,861. It lies in the Rechna Doab between the Chenab and Ravi rivers in the north-east of the Jhang district, and is designed to include an irrigated area of 25 million acres. The Chenab Canal (opened 1887) is the largest and most profitable perennial irrigation project of the Punjab. The Lamartin town is larapour, called after Sir J. Broadwood Lyall, lieutenant-governor of the Punjab 1887-1892, which gives its name to a district created in 1904.

CHÉNEDOLLÉ, CHARLES JULIEN LOIUT DE (1760-1833), French poet, was born at Vire (Calvados) on the 4th of November 1760. He early showed a vocation for poetry, but the outbreak of the Revolution temporarily diverted his energy. Emigrating in 1791, he fought two campaigns in the army of Condé, and eventually found his way to Hamburg, where he met Antoine de Rivarol, of whose brilliant conversation he has left an account. He also visited Mme de Staël in her retreat at Coppet. On his return to Paris in 1799 he met Chateaubriand and his sister Lucile (Mme de Caudé), to whom he became deeply attached. After her death in 1804, Chénédollé returned to Normandy, where he married and became eventually inspector of the academy of Caen (1812-1832).

The exception of occasional visits to Paris, he spent the rest of his life in his native province. He died at the château de Coisel on the 2nd of December 1853. He published his Génie de l'Homme in 1807, and in 1820 his Études politiques, which had the misfortune to appear shortly after the Revolution of Lamartine, so that the credit of their real originality. Chénédollé had many sympathies with the romanticists, and was a contributor to their organ, the Musée français. His other works include the Esprit de Rivarol (1808) in conjunction with F. J. M. Fayolle.

The works of Chénédollé were edited in 1864 by Sainte-Beuve, who drew portraits of him in his Châteaubriand et son groupe and in an article contributed to the Revue des deux mondes (June 1849). See also E. Helland, Étude biographique et littéraire sur Chénédollé (1857); Caizin, Notice sur Chénédollé (1869).

CHENERY, THOMAS (1826-1884), English scholar and editor of The Times, was born in 1826 at Barbados. He was educated at Eton and Caius College, Cambridge. Having been called to the bar, he went out to Constantinople as The Times correspondent just before the Crimean War, and it was under the influence there of Algernon Smythe (afterwards Lord Strangford) that he first turned to those philological studies in which he became eminent. After the war he returned to London and wrote regularly for The Times for many years, eventually succeeding Delane as editor in 1877. He was then an experienced publicist, particularly well versed in Oriental affairs, an indefatigable worker, with a rapid and comprehensive judgment, though he lacked Delane's intuition for public opinion. It was as an Orientalist, however, that he had meantime earned the highest reputation, his knowledge of Arabic and Hebrew being almost univalved and his gift for languages exceptional. In 1868 he was appointed Lord Almoner's professor of Arabic at Oxford, and retained his position until he became editor of The Times. He was one of the company of revisers of the Old Testament. He was secretary for some time to the Royal Asiatic Society, and published learned editions of the Arabic classic The Assemblies of Al-Hariri and of the Mabberoth Ithri. He died in London on the 11th of February 1884.

CHENG, T.SCHENG or TSCHIANG (Ger. Scheng), an ancient Chinese wind instrument, a primitive organ, containing the principle of the free reed which found application in the accordion, concertina and harmonium. The cheng resembles a tea-pot filled with bamboo pipes of graduated lengths. It consists of a gourd or turned wooden receptacle acting as wind reservoir, in the side of which is inserted an insufflation tube curved like a swan's neck or the spout of a tea-pot. The cup-shaped reservoir is closed by means of a plate of horn pierced with seventeen round holes arranged round the edge in an unfinished circle, into which fit the bamboo pipes. The pipes are cylindrical as far as they are visible above the plate, but the lower end inserted in the wind reservoir is cut to the shape of a beak, somewhat like the mouth-piece of the clarinet, to receive the reed. The construction of the free reed is very simple: it consists of a thin plate of metal—gold according to the Jesuit missionary Joseph Amiot,1 but brass in the specimens brought to Europe—of the thickness of ordinary paper. In this plate is a rectangular flap or tongue which remains fixed at one end, while at the other the tongue is filed so that, instead of closing the aperture, it passes freely through, vibrating as the air is forced through the pipe (see FREE-REEDED VIBRATOR).

The metal plate is fastened with wax longitudinally across the diameter of the beak end of the pipe, a little layer of wax being applied also to the free end of the vibrating tongue for the purpose of tuning by adding weight and impetus. About half an inch above the horn plate a small round hole or stop is bored through the pipe, which speaks only when this hole is covered by the finger. A longitudinal aperture about an inch long cut in the upper end of the bamboo pipe serves to determine the length of the vibrating column of air proper to respond to the vibrations of the free reed. The length of the bamboo pipe above this opening is purely ornamental, as are also four or five of the seventeen pipes which have no reeds and do not speak, being merely inserted for the purposes of symmetry in design. The notes of the cheng, like those of the concertina, speak either by inspiration or expiration of air, the former being the more usual method. Mahillon states that performers on the cheng in China are rare, as the method of playing by inspiration induces inflammation of the throat.2 Amiot, who gives a description of the instrument with illustrations showing the construction, states that in the great Chinese encyclopaedia Eush-ya, articles Yu and Ho, the Yu of ancient China was the large cheng with nineteen free reeds (twenty-four pipes), and the Ho the small cheng with thirteen reeds or seventeen pipes described in this article. The compass of the latter is given by him as the middle octave with chromatic intervals, the thirteenth note giving the octave of the first. Mahillon gives the compass of a modern cheng as follows:

![Diagram of the cheng](attachment:image.png)

E. F. F. Chladni,3 who examined a cheng sent from China to Herr Müller, organist of the church of St Nicholas, Leipzig, at the beginning of the 19th century, gives an excellent description of the instrument, reproducing in illustration a plate from Giulio Ferrario's work on costume.4 Müller's cheng had the same compass as Mahillon's. Chladni's article was motivated by the publication of an account of the exhibition of G. J. Grenié's Orgue expressif, invented about 1810, in the Conservatoire of Paris, which concludes: 5

4 Il Costume antico e moderno (Milan, 1816), pl. 66, vol. i.
some of the fragments are fine, its attempt at scientific exposition approximates too closely to the manner of Erasmus Darwin to suit a modern ear. Another fragment called L'Invention sums Chénier's Ars Poetica in the verse 4 Sur des pensers nouveaux, faisons des vers antiques. 5 Susanne represents the torso of a Biblical poem on a very large scale, in six cantos. In the meantime, André had published nothing, and some of these last pieces were in fact not yet written, when in November 1787 an opportunity of a fresh career presented itself. The new ambassador at the court of St. James's, M. de la Luzerne, was connected in some way with the Chénier family, and he offered to take André with him as his secretary. The offer was too good to be refused, but the poet hated himself on the banks of the fière Tamise, and wrote in bitter ridicule of 6

"Les Anglais. 7
Nacn toute à vendre à qui peut la payer,
De contrée en contrée allant au monde entier,
Offrir sa joie ignoble et son faste grossier."

He seems to have been interested in the poetic diction of Milton and Thomson, and a few of his verses are remotely inspired by Shakespeare and Gray. To say, however, that he studied English literature would be an exaggeration. The events of 1789 and the fermenting process of his younger brother, Marie-Joseph, as political playwright and pamphleteer, concentrated all his thoughts upon France. In April 1790 he could stand London no longer, and once more joined his parents at Paris in the rue de Cléry.

The France that he plunged into with such impetuosity was upon the verge of anarchy. A strong constitutionalist, Chénier took the view that the Revolution was already complete and that all that remained to be done was the inauguration of the reign of law. Moderate as were his views and disinterested as were his motives, his tactics were passionately and dangerously aggressive. From an idyllist and elegist we find him suddenly transformed into an unsparing master of poetical satire. His prose Avis au peuple français (August 24, 1790) was followed by the rhetorical Jeu de paume, a somewhat declamatory moral ode addressed "à Louis David, peintre." 8 In the meantime he énated at the Feuillants Club, and contributed frequently to the Journal de Paris from November 1791 to July 1792, when he wrote his scorching Tambique to Collot d'Herbois, Sur les Suisse revolts du régime de Châteauvieux. The 10th of August uprooted his party, his paper and his friends, and the management of relatives who kept him out of the way in Normandy alone saved him from the massacre of September. In the month following these events his democratic brother, Marie-Joseph, had entered the Convention. André's sombre rage against the course of events found vent in the line on the Maenads who mutilated the king's Swiss Guard, and in the Ode à Charlotte Corday congratulating France that "Un scélérat de moins rampe dans cette fange." At the express request of Malesherbes he furnished some arguments to the materials collected for the defence of the king. After the execution he sought a secluded retreat on the Plateau de Satory at Versailles and took exercise after nightfall. There he wrote the poems inspired by Fanny (Mme Laurent Lecouteulx), including the exquisite Ode à Versailles, one of his freshest, noblest and most varied poems.

His solitary life at Versailles lasted nearly a year. On the 7th of March 1794 he was taken at the house of Mme Piscator at Passy. Two obscure agents of the committee of public safety were in search of a marquis who had flown, but an unknown stranger was found in the house and arrested on suspicion. This was André, who had come on a visit of sympathy. He was taken to the Luxembourg and afterwards to Saint-Lazare. During the 140 days of his imprisonment there he wrote the marvellous Tambique (in alternate lines of 12 and 8 syllables), which hiss and stab like poisoned bullets, and which were transmitted to his family by a venal gaoler. There he wrote the best known of all his verses, the pathetic Jeune captive, a poem at once of enchantment and of despair. Suffocating in an atmosphere of cruelty and baseness, Chénier's agony found expression almost to the last in these murderous Tambique which he launched against the
Convention. Ten days before the end, the painter J. B. Suvée executed the well-known portrait. He might have been overlooked for the well-meaning, indignant officiousness of his father. Marie-Joseph had done his best to prevent this, but he could do nothing more. Robespierre, who was himself on the brink of the volcano, remembered the venomous sallies in the Journal de Paris. At sundown on the 25th of July 1794, the very day of his condemnation on a bogus charge of conspiracy, André Chénier was guillotined. The record of his last moments by La Touche is rather melodramatic and is certainly not above suspicion.

Incomplete as was his career—he was not quite thirty-two—his life was cut short in a crescendo of all its nobler elements. Exquisite as was already his susceptibility to beauty and his masteries of the rarest poetic material, we cannot doubt that Chénier was preparing for still higher flights of lyric passion and poetic intensity. Nothing that he had yet done could be said to compare in promise of assured greatness with the lampes, the Odes and the Jeune Captive. At the moment he left practically nothing to tell the world of his transcendent genius, and his reputation has had to be retrieved from oblivion page by page, and almost poem by poem. During his lifetime only his Jeu de paume (1791) and Hymne sur les Suisse (1792) had been given to the world. The Jeune Captive appeared in the Décade philosophique, Jan. 9, 1795; La Jeune Tarentine in the Mercure of March 1801. Chloeau's original offer of four passages in his Geste du christianisme.ayette and Lefeuve-Deumier also gave a few fragments; but it was not until 1819 that a first imperfect attempt was made by H. de la Touche to collect the poems in a substantive volume. Since the appearance of the edito princeps of Chénier's poems in La Touche's volume, many additional poems and fragments have been discovered, and an edition of the complete works of the poet, collated with the MSS. bequeathed to the Bibliothèque Nationale by Mme Elisa de Chénier in 1892, has been edited by Paul Dimoff and published by Delagrave. During the same period the critical estimates of the poet have fluctuated in a truly extraordinary manner. Sainte-Beuve in his Tableau of 1828 sang the praises of Chénier as an heroic forerunner of the Romantic movement and a precursor of Victor Hugo. Chénier, he said, had "inspired and determined" Romanticism. This suggestion of modernity in Chénier was echoed by a chorus of critics who worked the idea to death; in the meantime, the standard of his contemporary's works was being prepared by M. Becq de Fouquières and was issued in 1863, but rearranged and greatly improved by the editor in 1872. The same patient investigator gave his New Documents on André Chénier to the world in 1875.

In the second volume of La Vie littéraire d'Anatole France contests the theory of Sainte-Beuve. Far from being an imitator, he maintains that Chénier's poetry is the last expression of an expiring form of art. His matter and his form belong of right to the classic spirit of the 18th century. He is a contemporary, not of Hugo and Leconte de Lisle, but of Stuart and Morellet. M. Paguet sums up on the side of M. France in his volume on the 18th century (1890). Chénier's real disciples, according to the latest view, are Leconte de Lisle and M. de Heredia, mossaiets who have at heart the cult of antique and pagan beauty, of "pure art" and of "objective poetry." Heredia himself reverted to the judgment of Sainte-Beuve to the effect that Chénier was the first to make modern verses, and he adds, "I do not know in the French language a more exquisite fragment than the three hundred verses of the Bucoliques." Chénier's influence has been especially remarkable in Russia, where Pushkin imitated him, Kogloff translated La Jeune Captive, La jeune Tarentine and other famous pieces, while the critic Vesselovsky pronounces "Il a rétabli le lyrisme pur dans la poésie française."

The general French verdict on his work is in the main well summed by Morillot, when he says that, judged by the usual tests of the Romantic movement of the 'twenties (love for strange literatures of the North, medievalism, novelties and experiments), Chénier would inevitably have been excluded from the cénacle of 1827. On the other hand, he exhibits a decided tendency to the world-enmui and melancholy which was one of the earlier symptoms of the movement, and he has experimented in French verse in a manner which would have led to his excommunication by the typical performers of the 18th century. What is universally admitted is that Chénier was a very great artist, who like Ronsard opened up sources of poetry in France which had long seemed dried up. In England it is easier to feel his attraction for the English masters of the great romantic poets of the French poetry, for, rhetorical though he nearly always is, he yet reveals something of that quality which to the Northern mind has always been of the very essence of poetry, that quality which made Sainte-Beuve say of him that he was the first great poet "personnel et rêveur" in France since La Fontaine. His diction is still very artificial, the poetic diction of Delille transformed in the direction of Hugo, but not very much. On the other hand, his descriptive power in treating of nature shows far more art than the Triannin school ever attained. His love of the woodland and his political fervor often remind us of Shelley, and his delicate perception of Hellenic beauty, and the perfume of Greek legend, give us almost a foretaste of Keats. For these reasons, among others, Chénier, whose art is destined to so many vicissitudes of criticism in his own country, seems assured among English readers of a place among the Dii Majores of French poetry.

The Chénier literature of late years has become enormous. His life has been commemorated in numerous plays, pictures and poems, notably in the fine epilogue of Sully Prudhomme, the Stelio of A. de Vigny, the delicate statue by Puech in the Luxembourg, and the well-known portrait in the centre of the "Last Days of the Terror." The benefit of sons are all those of Barret, of Robespierre, for, by the 1872 and 1881), though these are now supplemented by those of L. Moland (2 vols., 1889) and R. Guillard (2 vols., 1899). (T.S.)

CHÉNIER, MARIE-JOSEPH BLAISE DE (1764-1811), French poet, dramatist and politician, younger brother of André de Chénier, was born at Constantinople on the 11th of February 1764. He was brought up at Carcassonne, and educated in Paris at the Collège de Navarre. Entering the army at seventeen, he left it two years afterwards; and at nineteen he produced Azmire, a two-act drama (acted in 1786), and Edgar, ou le page souffrant, a comedy (acted in 1785), which were failures. His Charles IX was kept back for nearly two years by the censor. Chénier attacked the censorship in three pamphlets, and the commotion aroused by the controversy raised keen interest in the piece. When it was at last produced on the 4th of November 1787, it achieved an immense success, due in part to its political suggestion, and in part to Talma's magnificent impersonation of Charles IX. Camille Desmoulins said that the piece had done more for the Revolution than the days of October, and a contemporary memoir-writer, the marquis de Ferrière, says that the audience came away "ivre de vengeance et tourné d'une soif de sang." The performance was the occasion of a split among the actors of the Comédie Française, and the new theatre in the Palais Royal, established by the dissidents, was inaugurated with Henri VIII (1791), generally recognized as Chénier's masterpiece; Jean Calas, ou l'école des juges followed in the same year. In 1792 he produced his Caius Gracchus, which was even more revolutionary in tone than its predecessors. It was nevertheless proscribed in the next year at the instance of the Montagnard deputy Albite, for an anti-anarchical hemistich (Des lois et non du sang!); Fénélon (1793) was suspended after a few representations; and in 1794 his Timoléon, set to Étienne Méhul's music, was also proscribed. This piece was played after the fall of the Terror, but the heat of the moment became the text for insinuations to the effect that by his silence Joseph de Chénier had connived at the judicial murder of André, whom Joseph's enemies alluded to as Abel. There is absolutely nothing to support the calumny, which has often been repeated since. In fact, after some fruitless attempts to save his brother, variously related by his biographers, Joseph became aware that André's only chance of safety lay in being forgotten by the authorities, and that ill-advised intervention would only hasten the end. Joseph Chénier had been a member of the Convention and of

1 This is the date given by G. de Chénier in his La Vérité sur la famille de Chénier (1844).
CHENILLE—CHEOPS

The council of Five Hundred, and had voted for the death of Louis XVI.; he had a seat in the tribunate; he belonged to the committees of public instruction, of general security, and of public safety. He was, nevertheless, suspected of moderate sentiments, and before the end of the Terror had become a marked man. His purely political career ended in 1802, when he was eliminated with others from the tribunate for his opposition to Napoleon. In 1801 he was one of the educational jury for the Seine; from 1803 to 1806 he was inspector-general of public instruction. He had allowed himself to be reconciled with Napoleon's government, and Cypri, represented in 1804, was written in his honour, but he was temporarily disgraced in 1806 for his Épitre à Voltaire. In 1806 and 1807 he delivered a course of lectures at the Athénée on the language and literature of France from the earliest years; and in 1808 at the emperor's request, he prepared his Tableau historique de l'état et du progrès de la littérature française depuis 1789 jusqu'à 1808, a book containing some good criticism, though marred by the violent prejudices of its author. He died on the 10th of January 1811.

The list of his works includes hymns and national songs—among others the famous Chant du départ; odes, Sur la mort de Mirebeau, Sur l'élogie de Robespierre, &c.; tragedies which never reached the stage, Brutus et Cassius, Philippe deux, Tithè; translations from Sophocles and Lessing, from Gray and Horace, from Tacitus and Aristotle; with elegies, dithyrambs and Ossianic rhapsodies. As a satirist he possessed great merit, though he sins from an excess of severity, and is sometimes malignant and unjust. He is the chief tragic poet of the revolutionary period, and as Camille Desmoulins expressed it, he decorated Melpomene with the tricolour cockade.

See the Œuvres complètes de Joseph Chénier (6 vols., Paris, 1823-1828), containing notices of the poet by Arnauld and Daunou; Chénier and the Théâtres de La littérature (1846); Henri Wallon, Recueil des Théâtres révolutionnaires, 1789-1799 (1881); and A. Lieby, Étude sur le théâtre de Marie-Joseph Chénier (1902).

CHENILLE (from the Fr. chenille, a hairy caterpillar), a twisted velvet cord, woven so that the short outer threads stand out at right angles to the central cord, thus giving a resemblance to a caterpillar. Chenille is used as a trimming for dresses and furniture.

CHENONCEAUX, a village of central France, in the department of Indre-et-Loire, on the right bank of the Cher, 20 m. E. by S. of Tours on the Orléans railway. Pop. (1906) 216. Chenonceaux owes its interest to its château (see Architecture: Renaissance Architecture in France), a building in the Renaissance style on the river Cher, to the left bank of which it is united by a two-storied gallery built upon five arches, and to the right by a drawbridge flanked by an isolated tower, part of an earlier building of the 15th century. Founded in 1525 by Thomas Bohier (d. 1523), financial minister in Normandy, the château was confiscated by Francis I. in 1535. Henry II. presented it to his mistress Diane de Poitiers, who on his death was forced to exchange it for Chaumont-sur-Loire by Catherine de' Medici. The latter built the gallery which leads to the left bank of the Cher. Chenonceaux passed successively into the hands of Louise de Vaudémont, wife of Henry III., the house of Vendôme, and the family of Bourbon-Condé. In the 18th century it came into the possession of the farmer-general Claude Dupin (1684-1760), who entertained the most distinguished personages in France, as well as foreign statesmen, within its walls. In 1864 it was sold to the chemist Théophile Pélouze, whose wife executed extensive restorations. It subsequently became the property of the Crédit Foncier, and again passed into private occupancy.

CHENOPODIUM, or Goose-foot, a genus of erect or prostrate herbs (natural order Chenopodiaceae), usually growing on the seashore or on waste or cultivated ground. The green angular stem is often striped with white or red, and, like the leaves, often more or less covered with mealy hairs. The leaves are entire, lobed or toothed, often more or less deltoid or triangular in shape. The minute flowers are bisexual, and borne in dense axillary or terminal clusters or spikes. The fruit is a membranous one-seeded utricle often enclosed by the persistent calyx. Ten species occur in Britain, in one of which, C. Bonus-Henricus, Good King Henry, is cultivated as a pot-herb, in lieu of asparagus, under the name mercury, and all good.

CHEOPS, in Herodotus, the name of the king who built the Great Pyramid in Egypt. Following on a period of good rule and prosperity under Ramphisnitus, Cheops closed the temples, abolished the sacrifices and made all the Egyptians labour for his monument, working in relays of 100,000 men every three months (see Pyramid). Proceeding from bad to worse, he sacrificed the honour of his daughter in order to obtain the money to complete his pyramid; and the princess built herself besides a small pyramid of the stones given to her by her lovers. Cheops reigned 50 years and was succeeded by his brother, Chephren, who reigned 36 years and built the second pyramid. During these two reigns the Egyptians suffered every kind of misery and the temples remained closed. Herodotus continues that in his own day the Egyptians were unwilling to name these oppressors and preferred to call the pyramids after a shepherd named Philiion, who pastured his flocks in their neighbourhood. At length Mycerinus, son of Cheops and successor of Chephren, reopened the temples and, although he built the Third Pyramid, allowed the oppressed people to return to their proper occupations.

Cheops, Chephren and Mycerinus are historical personages of the fourth Egyptian dynasty, in correct order, and they built the three pyramids attributed to them here. But they are wholly misplaced by Herodotus. Ramphisnitus, the predecessor of Cheops, appears to represent Rameses III. of the twelfth dynasty, and Mycerinus in Herodotus is but a few generations before Psammetichus, the founder of the twenty-sixth dynasty. Manetho correctly places the great Pyramid kings in Dynasty IV. In Egyptian the name of Cheops (Chemnisor Chembisin Diodorus Siculus, Suphis in Manetho) is spelt Hwfw (Khufu), but the pronunciation, in late times perhaps Khōufi, is uncertain. The Greeks and Romans generally accepted the view that Herodotus supplies of his character, and moralized on the uselessness of his stupendous work; but there is nothing else to prove that the Egyptians themselves executed his memory. Modern writers rather dwell on the perfect organization demanded by his scheme, the training of a nation to combined labour, the level attained here by art and in the fitting of masonry, and finally the fact that the last remains of the great wonders of the ancient world and now alone of them survives. It seems that representations of deities, and indeed any representations at all, were rare upon the polished walls of the great monuments of the fourth dynasty, and Petrie thinks that he can trace a violent religious revolution with confiscation of endowments at this time in the temple remains at Abydos; but none the less the wants of the deities were then attended to by priests selected from the royal family and the highest in the land. Khufu's work in the temple of Bubastis is proved by a surviving fragment, and he is figured slaying his enemy at Sinai before the god Thoth. In late times the priests of Denderah claimed Khufu as a benefactor; he was reputed to have built temples to the gods near the Great Pyramids and Sphinx (where also a pyramid of his daughter Hentsen is spoken of), and there are incidental notices of him in the medical and religious literature. The funerary cult of Khufu and Khafre was practised under the twenty-sixth dynasty, when so much that had fallen into disuse and which Khufu had forgotten was revived. Khufu is a leading figure in an ancient Egyptian story (Papyrus Westcar), but it is unfortunately incomplete. He was the founder of the fourth dynasty, and was probably born in Middle Egypt near Beni Hasan, in a town afterwards known as "Khufu's Nurse," but was connected with the Memphite third dynasty. Two tablets at the mines of Wadi Maghara in the peninsula of Sinai, a granite block from Bubastis, and a beautiful ivory statuette found by Petrie in the temple at Abydos, are almost all that can be definitely assigned to Khufu outside the pyramid at Giza and its ruined accompaniments. His date, according to Petrie, is 3960-3908 B.C., but in the shorter chronology of Meyer, Breasted and others he reigned (23 years) about a thousand years later, c. 2900 B.C.
CHEPSTOW, a market town and river-port in the southern parliamentary division of Monmouthshire, England, on the Wye, 2 m. above its junction with the Severn, and on the Great Western railway. Pop. of urban district (1901) 3067. It occupies the slope of a hill on the western (left) bank of the river, and is environed by beautiful scenery. The church of St Mary, originally the conventual chapel of a Benedictine priory of Norman foundation, has remains of that period in the west front and the nave, but a rebuilding of the chancel and transept was effected in the last quarter of the 13th century. The church contains many interesting monuments. The castle, still a magnificent pile, was founded in the 11th century by William Fitz-Osbern, earl of Hereford, but was almost wholly rebuilt in the 13th. There are, however, parts of the original building in the keep. The castle occupies a splendid site on the summit of a cliff above the Wye, and covers about 3 acres. The river is crossed by a fine iron bridge of five arches, erected in 1816, and by a tubular railway bridge designed by Sir Isambard Brunel. There is a free passage on the Wye for large vessels as far as the bridge. From the narrowness and depth of the channel the tide rises suddenly and to a great height, forming a dangerous bore. The exports are timber, bark, iron, coal, cider and millstones. Some shipbuilding is carried on.

As the key to the passage of the Wye, Chepstow (Estrigores, Strigwill) was the site successively of British, Roman and Saxon fortifications. Domesday Book records that the Norman castle was built by William Fitz-Osbern to defend the Roman road into South Wales. On the confiscation of his son's estates the castle was granted to the earls of Pembroke, and after its reversion to the crown in 1306, Edward II. in 1310 granted it to his half-brother Thomas de Brotherton. On the latter's death it passed, through his daughter Margaret, Lady Segrave, to the dukes of Norfolk, from whom, after again reverting to the crown, it passed to the earls of Worcester. It was confiscated by parliament and settled on Oliver Cromwell, but was restored to the earls in 1660. The borough must have grown up between 1310, when the castle and ville were granted to Thomas de Brotherton, and 1342, when John duke of Norfolk died seized of the castle, manor and borough of Strigwill. In 1524 Charles, first earl of Worcester and then lord of the Marches, granted a new charter of incorporation to the bailiffs and burgesses of the town, which had fallen into decay. This was sustained until the reign of Charles II., when, some dispute arising between the earl of Bridgewater and the burgesses, no bailiff was appointed and the charter lapsed. Chepstow was afterwards governed by a board of twelve members. A port since early times, when the lord took duty of the goods up and down the coast, it had no ancient market and no manufactures but that of glass, which was carried on for a short time within the ruins of the castle.

CHEQUE, or CHECK, in commercial law, a bill of exchange drawn on a banker and signed by the drawer, requiring the banker to pay on demand a certain sum in money to or to the order of a specified person or to bearer. In this, its most modern sense, the cheque is the outcome of the growth of the banking system of the 15th century. For details see BANK AND BANKING: Law, and BILL OF EXCHANGE. The word check, of which "cheque" is a variant now general in English usage, signified merely the counterfeit or indorse of an exchequer bill, or any draft form of payment, on which was registered the particulars of the principal part, as a check to alteration or forgery. The original meaning of "check" is a move in the game of chess which, while it attacks the king, the word comes through the Old Fr. escher, escaec, from the Med. Lat. form sessaeis of the Persian șāh, king, i.e. the king in the game of chess; cf. the origin of "mate" from the Arabic șāh-māt, the king is dead. The word was early used in a transferred sense of a stoppage or rebuf, and so is applied to anything which stops or hinders a matter in progress, or which controls or restrains anything, hence a token, ticket or counterfoil which serves as a means of identification, &c.

See Herodotus ii. 124; Dio Cassius i. 64; Sethe in Pauly-Wissowa's Realencyclopdie, s.v.; W. M. F. Petrie, History of Egypt, vol. i., and Abydos, part ii. p. 48; J. H. Breasted, History. (F. Ll. G.)

81

check or counterfoil parts remained in the hands of the banker, the portion given to the customer being termed a " drawn note ", or " draft." From the beginning of the 10th century the word "cheque" gradually became synonymous with "draft" as meaning a written order on a banker by a person having money in the banker's hands, to pay some amount to bearer or to a person named. Ultimately, it entirely superseded the word " draft," and has now a statutory definition (Bill of Exchange Act 1882, s. 73)— a bill of exchange drawn on a banker payable on demand. The word "draft" has come to have a wider meaning, that of a bill drawn by one person on another for a sum of money, or an order (whether on a banker or other) to pay money. The employment of cheques as a method of payment offering greater convenience than coin is almost universal in Great Britain and the United States. Of the transactions through the banks of the United Kingdom between 86 and 90% are conducted by means of cheques, and an even higher proportion in the United States. On the continent of Europe the use of cheques, formerly rare, is becoming more general, particularly in France, and to some extent in Germany.
15th centuries and a château of later date. Drevant, built on the site of a Roman town, preserves ruins of a large theatre and other remains. Among the megalithic monuments of Cher, the most notable is that at Villeneuve-sur-Che, known as the Pierre-de-la-Roche.

CHERAT, a hill town situated on the Peshawar district of the North-West Frontier Province, India, 34 m. S.E. of Peshawar. It is situated at an elevation of 4,500 ft., on the west of the Khattak range, which divides the Peshawar from the Kohat district. It was first used in 1861, and since then has been employed during the hot weather as a health station for the British troops quartered in the hot and malarious vale of Peshawar.

CHERBOURG, a naval station, fortified town and seaport of north-western France, capital of an arrondissement in the department of Manche, on the English Channel, 232 m. W.N.W. of Paris on the Ouest-État railway. Pop. (1906) town, 35,710; commune, 43,587. Cherbourg is situated at the mouth of the Divette, on a small bay at the apex of the indentation formed by the northern shore of the peninsula of Cotentin. Apart from a fine hospital and the church of La Trinité dating from the 12th century, the town has no buildings of special interest. A rich collection of paintings is housed in the hôtel de ville. A statue of the painter J. F. Millet, born near Cherbourg, stands in the public garden, and there is an equestrian statue of Napoleon I. in the square named after him. Cherbourg is a fortified place of the first class, headquarters of one of the five naval arrondissements of France, and the seat of a sub-prefect.

It has tribunals of first instance and of commerce, a chamber of commerce, a lycée and a naval school. The chief industries of the town proper are fishing, saw-milling, tanning, leather-dressing, ship-building, iron and copper-founding, rope-making and the manufacture of agricultural implements. There are stone quarries in the environs, and the town has trade in farm produce.

Cherbourg derives its chief importance from its naval and commercial harbours, which are distant from each other about half a mile. The former consists of three main basins cut out of the rock, and has an area of 53 acres. The minimum depth of water is 30 ft. Connected with the harbour are dry docks, the yards where the largest ships in the French navy are constructed, magazines, rope walks, and the various workshops requisite for a naval arsenal of the first class. The works and town are carefully guarded on every side by redoubts and fortifications, and are commanded by batteries on the surrounding hills. There is a large naval hospital close to the harbour. The commercial harbour at the mouth of the Divette communicates with the sea by a channel 650 yds. long. It consists of two ports, an outer and tidal harbour 173 acres in extent, and an inner basin 15 acres in extent, with a depth of soil at ordinary spring tide of 25 ft. Outside these harbours is the triangular bay, which forms the roadstead of Cherbourg. The bay is admirably sheltered by the land on every side but the north. On that side it is sheltered by a huge breakwater, over 2 m. in length, with two arms of 700 and 500 ft. at its base, and 30 ft. in the middle, which is protected by forts, and leaves passages for vessels to enter from east and west. These passages are guarded by forts placed on islands intervening between the breakwater and the mainland, and themselves united to the land by breakwaters. The surface within these barriers amounts to about 3,700 acres. Cherbourg is a port of call for the American, North German Lloyd and other important lines of transatlantic steamers. The chief exports are stone for road-making, butter, eggs and vegetables; the chief imports are coal, timber, superphosphates and wine from Algeria. Great Britain is the principal customer.

Cherbourg is supposed by some investigators to occupy the site of the Roman station of Coriellum, but nothing definite is known about its origin. The name was long regarded as a corruption of Caesaris Burges (Caesar's Borough). William the Conqueror, under whom it appears as Carnabar, provided it with a hospital and a church; and Henry II. of England on several occasions chose it as his residence. In 1295 it was pillaged by an English fleet from Yarmouth; and in the 14th century it frequently suffered during the war against the English. Captured by the English in 1418 after a four months' siege, it was recovered by Charles VII. of France in 1450. An attempt was made under Louis XIV. to construct a military port; but the fortifications were dismantled in 1658, and further damage was inflicted by the English in 1758. In 1686 Vauban planned a harbour-work which were begun under Louis XVI. and continued by Napoleon I. It was left, however, to Louis Philippe, and particularly to Napoleon III., to complete them, and their successful realization was celebrated in 1858, in the presence of the queen of England, against whose dominions they had at one time been mainly directed. At the close of 1857, £8,000,000, of which the breakwater cost over £2,500,000, had been expended on the works; in 1889 a further sum of £500,000 was voted by the Chamber of Deputies for the improvement of the port.

CHERBULIEZ, CHARLES VICTOR (1829-1899), French novelist and miscellaneous writer, was born on the 19th of July 1829, at Geneva, where his father, André Cherbuliez (1793-1874), was a classical professor at the university. He was descended from a family of Protestant refugees, and many years later Victor Cherbuliez resumed his French nationality, taking advantage of an act passed in the early days of the Revolution. Geneva was the scene of his early education; thence he proceeded to Paris, and afterwards to the universities of Bonn and Berlin. He returned to his native town and engaged in the profession of teaching. After his resumption of French citizenship he was elected a member of the Academy (1881), and having received the Legion of Honour in 1870, he was promoted to be officer of the order in 1892. He died on the 1st of July 1899. Cherbuliez was a voluminous and successful writer of fiction. His first book, originally published in 1860, reappeared in 1864 under the title of Un Cheval de Phidias: it is a romantic study of art in the golden age of Athens. He went on to produce a series of novels, of which the following are the best known.—Le Comte Kostiha (1863), Le Prince Vital (1864), Le Roman d'une hôtesse femme (1869), L'Acustica (1870), Miss Rose (1872), Samuel Broli et Cie (1877), L'Idée de Jean Terral (1873), Noirs et rouges (1881), La Vocation du Comte Ghislain (1888), Une Goëlette (1890), Le Secret du précepteur (1893), Jacqueline Veness (1898), &c. Most of these novels first appeared in the Revue des deux mondes, to which Cherbuliez also contributed a number of political and learned articles, usually printed with the pseudonym G. Valbert. Many of these have been published in collected form under the titles L'Allemagne politique (1870), L'Espagne politique (1874), Profils étrangers (1880), L'Art et la nature (1893), &c. The volume Études de littérature et d'art (1873) includes articles for the most part reprinted from Le Temps. The earlier novels of Cherbuliez have been said with truth to show marked traces of the influence of George Sand; and in spite of modification, his method was that of an older school. He did not possess the sombre power or the intensely analytical skill of some of his later contemporaries, but his books are distinguished by a freshness and honesty, fortified by cosmopolitan knowledge and a strong sense of humour, which fully account for their wide popularity in many countries besides his own. His genius was the reverse of dramatic, and attempts to present two of his stories on the stage have not succeeded. His essays have all the merits due to liberal observation and thoroughness of treatment; their style, like that of the novels, is admirably lucid and correct.

CHERCHEL, a seaport of Algeria, in the arrondissement and department of Algiers, 55 m. W. of the capital. It is the centre of an agricultural and vine-growing district, but is commercially of no great importance, the port, which consists of part only of the inner port of Roman days, being small and the entry difficult. The town is chiefly noteworthy for the extensive ruins of former cities, identical to the same site. Of existing buildings the most remarkable is the great Mosque of the Hundred Columns, now used as a military hospital. The mosque contains 80 columns of diorite, surmounted by a variety of capitals brought from other buildings.
The population of the town in 1906 was 4735 of the commune of which Cherchel is the centre 11,088.

Cherchel was a city of the Carthaginians, who named it Jol. Juba II. (25 B.C.) made it the capital of the Mauretanian kingdom under the name of Caesarea. Juba's tomb, the so-called Tombeau de la Chrétienne (see Algeria), is 1/2 m. E. of the town. Destroyed by the Vandals, Caesarea regained some of its importance under the Byzantines. Taken by the Arabs it was renamed by them Cherchel. Khaire-de-Din Barbarossa captured the city in 1520 and annexed it to his Algerian pashalik.

In the early years of the 18th century it was a commercial city of some importance, but was laid in ruins by a terrible earthquake in 1738. In 1840 the town was occupied by the French. The ruins suffered greatly from vandalism during the early period of French rule, many portable objects being removed to museums in Paris or Algiers, and most of the monuments destroyed for the sake of their stone. Thus the dressed stones of the ancient theatre served to build barracks; the material of the hippodrome went to build the church; while the portico of the hippodrome, supported by granite and marble columns, and approached by a fine flight of steps, was destroyed by Cardinal Lavergne in a search for the tomb of St Marcianus. The fortress at Cherchel was built by Raniq Barbarossa, elder brother of Khaire-de-Din, was completely destroyed by the French. There are many fragments of a white marble temple. The ancient cisterns still supply the town with water. The museum contains some of the finest statues discovered in Africa. They include colossal figures of Aesculapius and Bacchus, and the lower half of a seated Egyptian divinity in black basalt, bearing the cartouche of Tethmosis (Thothmes) I. This statue was found at Cherchel, and is held by some archaeologists to indicate an Egyptian settlement here about 1500 B.C.

See Africa, Roman, and the description of the museum by P. Gauckler in the Musées et collections archéologiques de l'Algérie.

CHERCHEN, a town of East Turkestan, situated at the northern foot of the Altyn-tagh, a range of the Kuen-lun, in 83° 35' E. and on the Cherchen-darya, at an altitude of 4100 ft. It straggles mostly along the irrigation channels that go off from the left side of the river, and in 1900 had a population of about 2000. The Cherchen-darya, which rises in the Arkha-tagh, a more southerly range of the Kuen-lun, at 36° 20' N., flows north for 200 m., then descends below Cherchen and Cherimai, and turns north-east and meanders through a wide bed (300-400 ft.), beset with dense reeds and flanked by older channels. It is probable that earlier it entered the dissected channel of the Ettek-tarim, but at present it joins the existing Tarim in the lake of Kara-buran, a sort of lacustrine "ante-room" to the Kara-koshun (N. M. Przevalsky's Lop-nor). At its entrance into the former lake the Cherchen-darya forms a broad delta. The river is frozen in its lower course for two to three months in the winter. From the foot of the mountains to the oasis of Cherchen it has a fall of nearly 4000 ft., whereas in the 300 m. or so from Cherchen to the Kara-buran the fall is 1400 ft. The total length is 500-600 m., and the drainage basin measures 6000-7000 sq. m.

See Sven Helin, Scientific Results of a Journey in Central Asia, 1899-1902, vols. i. and ii. (1905-1906); also TAKLA-MAKAN.

CHEREMISSES, or TCHEREMISSES, a Finnish people living in isolated groups in the governments of Kazan, Viatka, Novgorod, Perm, Kostroma and Ufa, eastern Russia. Their name for themselves is Mark-Met. Many people are generally identifiable with the ancient Merians of Suzdalia. Their language belongs to the Finno-Ugrian family. They number some 240,000. There are two distinct physical types: one of middle height, black-haired, brown skin and flat-faced; the other short, fair-haired, white skinned, with narrow eyes and straight short noses. Those who live on the right bank of the Volga are sometimes known as Hill Cheremis, and are taller and stronger than those who inhabit the swamps of the left bank. They are farmers and herd horses and cattle. Their religion is a hotchpotch of Shamanism, Mahommedanism and Christianity. They are usually monogamous. The chief ceremony of marriage is a forcible abduction of the bride. The women, naturally ugly, are often disfigured by sore eyes caused by the smoky atmosphere of the huts. They wear a head-dress, trimmed with glass jewels, forming a hood behind stiffened with metal. On their breasts they carry a breastplate formed of coins, small bells and copper disks.

See Smirnov, Mœurs et Tcheremisses (Paris, 1895); J. Abercromby, Pre- and Proto-historic Finns (London, 1898).

CHERIBON, a residency of the island of Java, Dutch East Indies, bounded S. and W. by the Preanger regencies, N.W. by Krawang, N. by the Java Sea, and E. by the residences of Tegal and Banyumas. Pop. (1897) 1,577,521, including 867 Europeans, 21,708 Chinese, and 196 Arabs and other Asiatic foreigners. The natives consist of Middle Javanese in the north and Sundanese in the south. Cheribon has been for many centuries the centre of Islamism in western Java, and is also the seat of a fanatical Mahomedan sect controlled from Mecca. The native population is on the whole orderly and prosperous. The northern half of the residency is flat and marshy in places, especially in the north-west corner, while the southern half is mountainous. In the middle stands the huge volcano Cherimai, clad with virgin forest and coffee plantations, and surrounded at its foot by rice and coffee plantations. To the south of Preanger border is the Sawal volcano, at whose foot is the beautiful lake of Palimanan.

Sulphur and salt springs occur on the slopes of Cherimai, and near Palimanan there is a cavernous hole called Gwagalang (or Payagalang), which exhauses carbonic acid gas, and is considered holy by the natives and guarded by priests. There is a similar hole in the Preanger. The principal products of cultivation are sugar, coffee, rice and also tea and pulse (raochong), the plantations being for the most part owned by Europeans. The chief towns are Cheribon, a seaport and capital of the residency, the seaport of Indramaya, Palimanan, Majoranga, Kuningan and Chiamis. Cheribon has a good open roadstead. The town is very old and irregularly built, and the climate is unhealthy; nevertheless it has a lively export trade in sugar and coffee and is a regular port of call. In 1908 the two descendants of the old sultans of Cheribon still resided there in their respective kratons or palaces, and each received an annual income of over £1500 for the loss of his privileges. A country residence belonging to one of the sultans is situated close to Cheribon and is much visited on account of its fantastic architecture. Indramaya was a considerable trading place in the days of the early Portuguese and Dutch traders. Kuningan is famous for a breed of small but strong horses.

CHERSKASY (Polish, Czerskazy), a town of Russia, in the government of Kiev, 66 m. S.E. of Kiev, on the right bank of the Dnieper. Pop. (1883) 15,740; (1897) 26,619. The inhabitants (Little Russians) are mostly employed in agriculture and gardening; but sugar and tobacco are manufactured and spirits distilled. Cherskasy was an important town of the Ukraine in the 15th century, and remained so, under Polish rule, until the revolt of the Cossack hetman Chmielnicki (1648). It was annexed by Russia in 1795.

CHERNIGOV, a government of Little Russia, on the left bank of the Dnieper, bounded by the governments of Mogilev and Smolensk on the N., Orel and Kursk on the E., Poltava on the S., and Kiev and Minak on the W. Area, 20,233 sq. m. Its surface is an undulating plain, 650 to 750 ft. high in the north and 370 to 600 ft. in the south, deeply grooved by ravines and the valleys of the rivers. In the north, beyond the Desna river, and on the north of the 55th parallel, lies a desert which is occupied by the black earth soil, and marshes occur along the course of the river. In the south of the Desna the soil is dry and sometimes sandy, and gradually it assumes the characters of a steppe-land as one proceeds southward. The government is drained by the Dnieper, which forms its western boundary for 180 m., and by its tributary the Desna. The latter, which flows through Chernigov for nearly 350 m., is navigable, and timber is brought down its tributaries. The climate is much colder in the wooded tracts of the north than in the south; the average yearly temperature at the city of Chernigov is 44.4° F. (January, 23°; July 68°-5). The population reached 1,966,350 in 1883, 2,316,818 in 1897,
and 2,400,300 (estimate) in 1906. It is chiefly Little Russian (85.6%); but Great Russians (6.1%), mostly Raskólniks, i.e. nonconformists, and White Russians (5.6%) inhabit the northern districts. There are, besides, some Germans, as well as Greeks, at Nyzhyn. Agriculture is the principal occupation; in the north, however, many of the inhabitants are engaged in the timber trade, and in the production of tar, pitch, wooden wares, leather goods and so forth. Cattle-breeding is carried on in the central districts. Bee-keeping is extensively carried on by the Raskólniks. Limestone, grindaones, china-clay and building-stone are quarried. Manufactures have begun to develop rapidly of the most important being sugar-works, distilleries, cloth-mills and glass-works. The government is divided into fifteen districts, their chief towns being Chervnigov (9.5%), Borzna (pop. 12,458 in 1897), Glukhov (14,856), Gorodna (4197), Konotop (23,083), Kozelets (5160), Krolevets (10,375), Mglin (7631), Novgorod-Svyersk (9185), Novozybkov (15,480), Nyzhyn (32,481), Oster (5384), Sosnitsa (1507), Starodub (12,453) and Svityaz (905).

CHERNOGÓR—CHERRY

The county of Russia, capital of the above government, on the right bank of the Desna, nearly half a mile from the river, 141 m. by rail N.E. of Kiev on a branch line. Pop. (1897) 27,006. It is an archiepiscopal see and possesses a cathedral of the 11th century. In 907 the city is mentioned in the treaty of Oleg as next in importance to Kiev, and in the 11th century it became the capital of the principality of Svyersk and an important commercial city. The Mongol invasion put an end to its prosperity in 1239. Lithuania annexed it in the 14th century, but it was soon seized by Poland, which held it until the 17th century. In 1686 it was definitively annexed to Russia.

CHEROKEE (native Tsalagi, "cove people"), a tribe of North American Indians of Iroquoian stock. Next to the Nuvaho they are the largest tribe in the United States and live mostly in Oklahoma (formerly Indian territory). Before their removal they possessed a large tract of country now distributed among the states of Alabama, Georgia, Mississippi, Tennessee and the west of Florida. Their chief divisions were then settled around the head-waters of the Savannah and Tennessee rivers, and were distinguished as the Elati Tsalagi or Lower Cherokees, i.e. those in the plains, and Atali Tsalagi or Upper Cherokees, i.e. those on the mountains. They were further divided into seven exogamous clans. Fernando de Soto travelled through their country in 1540, and during the next three centuries they were important factors in the history of the south. They attached themselves to the English in the disputes and contests which arose between the European colonizers, formally recognized the English king in 1730, and in 1755 ceded a part of their territory and permitted the erection of English forts. Unfortunately this amity was interrupted not long after; but peace was again restored in 1761. When the revolutionary war broke out they sided with the royalist party. This led to their subjugation by the new republic, and they had to surrender that part of their lands which lay to the south of the Savannah and east of the Chattahoochee. Peace was made in 1781, and in 1785 they were compelled to recognize the government of the United States, and were confirmed in their possession. In 1820 they adopted a civilized form of government, and in 1827, as a "Nation," a formal constitution. The gradual advance of white immigration soon led to disputes with the settlers, who desired their removal, and exodus after exodus took place; a small part of the tribe agreed (1835) to remove to another district, but the main body remained. An appeal was made by them to the United States government; but President Andrew Jackson refused to interfere. A force of 2000 men, under the command of General Winfield Scott, was sent in 1838, and the Cherokees were compelled to emigrate to their present position. After the settlement various disagreements between the eastern and western Cherokees continued for some time, but in 1839 a union was effected. In the Civil War they all at first sided with the South; but before long a strong party joined the North, and this led to a disastrous internecine struggle. On the close of the conflict they were confirmed in the possession of their territory, but were forced to give a portion of their lands to the eman- cipated slaves. Their later history is mainly a story of hopeless struggle to maintain their tribal independence against the white man. In 1892 they sold their western territory known as the "Cherokee outlet." Until 1906, when tribal government virtually ceased, the "nation" had an elected chief, a senate and house of representatives. Many of them have become Christians, schools have been established and there is a tribal press. Those in Oklahoma still number some 26,000, though most are of mixed blood. A group, known as the Eastern Band, some 1400 strong, are on a reservation in North Carolina. Their language consists of two dialects—a third, that of the "Lower" branch, having been lost. The syllabic alphabet invented in 1821 by George Guess (Sequoyah) is the character employed. See also Handbook of American Indians (Washington, 1907); T. V. Parke, Cherokee Indians (N. Y., 1909); and Indians, North American.

CHEROOT, or SHEROOT (from the Tamil word "shuruttu," a roll), a cigar made from tobacco grown in southern India and the Philippine Islands. It was once esteemed very highly for its delicate flavour. A cheeroot differs from other cigars in having both ends cut square, instead of one being pointed, and one end considerably larger than the other.

CHEERAPUNJI, a village in the Khali hills district of Assam. It is notable as having the heaviest known rainfall in the world. In 1861 it registered a total of 905 in., and its annual average is 458 in. This excessive rainfall is caused by the fact that Chewrapunji stands on the edge of the plateau overlooking the plains of Bengal, where it catches the full force of the monsoon as it rises from the sea. There is a good coal-seam in the vicinity.

CHERRY. As a cultivated fruit-tree the cherry is generally supposed to be of Asiatic origin, whence, according to Pliny, it was brought to Italy by Lucullus after his defeat of Mithridates, king of Pontus, 68 B.C. As with most plants which have been long and extensively cultivated, it is a matter of difficulty, if not an impossibility, to identify the parent stock of the numerous cultivated varieties of cherry; but they are generally referred to two species: Prunus Cerastus, the wild or dwarf cherry, the origin of the morello, duke and Kentish cherries, and P. Avium, the gean, the origin of the geans, hearts and bigarreus. Both species grow wild through Europe and western Asia to the Himalayas, but the dwarf cherry has the more restricted range of the two in Britain, as it does not occur in Scotland and is rare in Ireland. The cherries form a section Cerastus of the genus Prunus; and they have sometimes been separated as a distinct genus from the plums proper; both have a stone-fruit or drupe, but the drupe of the cherry differs from that of the plum in not having a waxy bloom; further, the leaves of the plum are rolled (concute) in the bud, while those of the cherry are folded (conuplicate).

The cherries are trees of moderate size and shrubs, having smooth, serrate leaves and white flowers. They are natives of the temperate regions of both hemispheres; and the cultivated varieties ripen their fruit in Norway as far as 63° N. The geans are generally distinguished from the common cherry by the greater size of the trees, and the deeper colour and comparative insipidity of the flesh in the ripe fruit, which adheres firmly to the "nut" or stone; but among the very numerous cultivated varieties specific distinctions shade away so that the fruit cannot be ranged under these two heads. The leading varieties are recognized as bigarreus, dukas, morellos and geans. Several varieties are cultivated as ornamental trees and on account of their flowers.

The cherry is a well-flavoured sub-acid fruit, and is much esteemed for preserves. Some of the varieties are particularly selected for pies, tarts, &c., and others for the preparation of preserves, and for making cherry brandy. The fruit is also very extensively employed in the preparation of the liqueurs known as kirschwasser, ratafia and maraschino. Kirschwasser is made.
chiefl y on the upper Rhine from the wild black gean, and in the manufacture the entire fruit-flesh and kernels are pulped up and allowed to ferment. By distillation of the fermented pulp the liqueur is obtained in a pure, colourless condition. Ratafia is similarly established, only by preference from a gean. Maraschino, a highly valued liqueur, the best of which is produced at Zara in Dalmatia, differs from these in being distilled from a cherry called marasca, the pulp of which is mixed with honey, honey or sugar being added to the distillate for sweetening.

It is also said that the flavour is heightened by the use of the leaves of the perfumed cherry, Prunus Mahaleb, a native of central and southern Europe.

The wood of the cherry tree is valued by cabinetmakers, and that of the gean tree is largely used in the manufacture of tobacco pipes. The American wild cherry, Prunus serotina, is much sought after, its wood being compact, fine-grained, not liable to warp, and susceptible of receiving a brilliant polish.

The kernels of the perfumed cherry, P. Mahaleb, are used in confectionery and for scent. A gum exudes from the stem of cherry trees similar in its properties to gum arabic.

Forcing

The cherry is increased by budding on the wild gean, obtained by sowing the stones of the small black or red wild cherries. To secure very dwarf trees the Prunus serotina has hitherto been used for the May duke, Kentish, and analogous sorts, but it is not adapted for strong-growing varieties like the bigarreau.

The stocks are budded, or, more rarely, grafted, at the usual seasons. The cherry prefers a free, loamy soil, with a well-drained subsoil. Stiff soils and dry gravelly subsoils are both unsuitable, though the trees require a large amount of moisture, particularly the large-leaved sorts, such as the bigarreau. For standard trees, the bigarreau section should be planted 30 ft. apart, or more, in rich soil, and the May duke, morello and similar varieties 20 or 25 ft. apart; while, as trained trees against walls and espaliers, from 20 to 24 ft. should be allowed for the former, and from 15 to 20 ft. for the latter. In forming the stems of a standard tree the temporary side-shoots should not be allowed to attain too great a length, and should not be more than two years old when they are cut close to the stem. The first three shoots retained to form the head should be short, to about 15 in., and two shoots from each encouraged, one at the end, and the other 3 or 4 in. lower down. When these have become well established little pruning will be required, and that chiefly to keep the principal branches as nearly equal in strength as possible for the first few years. Espalier trees should have the branches about a foot apart, starting from the stem with an upward curve, and then being trained horizontally. In summer pruning the shoots on the upper branches must be shortened at least a week before those on the lower ones. After a year or two clusters of fruit buds will be developed on horizontally along the branches, and those spurs will continue productive for an indefinite period. For wall trees any form of training may be adopted; but as the fruit is always finest on young spurs, fan-training is probably the most advantageous. A succession of young shoots should be laid in every year. The morello, which is of twigg y growth and bears on the young wood, must be trained in the fan form, and care should be taken to avoid the very common error of crowding its branches.

Forcing—The cherry will endure a high temperature nor close atmosphere. A heat of 45° at night will be sufficient at starting, this being gradually increased during the first few weeks to 55°, but lowered again when the blossom buds are about to open. After toning the temperature may be again gradually raised to 60°, and may go up to 70° by day, or 75° by sun heat, and 60° at night. The best forcing cherries are the May duke and the royal duke, the duke cherries being of more compact growth than the bigarreau tribe and generally setting better; nevertheless a few of the larger kinds, such as bigarreau Napoleoné, black tartarian and St Margaret's, should be forced for variety. The trees may be either planted out in tolerably rich soil, or grown in large pots of good turfy friable calcareous loam mixed with rotted dung. If the plants are small, they may be put into 12-in. pots in the first instance, and after a year shifted into 15-in. pots early in autumn, and plunged in some loose or even very slightly fermenting material. The soil of the pots should be protected from snow-showers and cold rains. Occasionally trees have been taken up in autumn with balls, potted and forced in the following spring; but those which have been established a year in the pots are to be preferred. Such only as are well furnished with blossom-buds should be selected. The trees should be removed to the forcing house in the beginning of December, if fruit be required very early in the season. During the first and second weeks it may be kept nearly close; but, as vegetation advances, air becomes absolutely necessary during the day, and even at night when the weather will permit. If forcing is commenced about the middle or third week of December, the fruit ought to be ripe by about the end of March. After the fruit is gathered, the trees should be duly supplied with water at the root, and the foliage kept well syringed till the wood is mature. (See also Fruit and Flower Farming.)

CHERRYVALE, a city of Montgomery county, Kansas, U.S.A., about 140 m. S.S.E. of Kansas City. Pop. (1890) 2104; (1900) 3472, including 180 negroes; (1910) 5088; (1910) 4304. It is served by the Atchison, Topeka & Santa Fé and the Northwestern, and is on the line of which it is a stop of the Missouri, Kansas & San Francisco railways. It is in a farming district and in the Kansas natural-gas and oil-field, and has large zinc smelters, an oil refinery, and various manufactures, including vitrified brick, flour, glass, cement and ploughs. Cherryvale was laid out in 1871 by the Kansas City, Lawrence & South Kansas Railway Company (later absorbed by the Atchison, Topeka & Santa Fé). The main part of the town was destroyed by fire in 1873, but was soon rebuilt, and in 1880 Cherryvale became a city of the third and afterwards of the second class. Natural gas, which is used as a factory fuel and for street and domestic lighting, was found here in 1885, and oil several years later.

CHERRY VALLEY, a village of Otsego county, New York, U.S.A., in a township of the same name, 68 m. N.W. of Albany. Pop. (1890) 685; (1900) 772; (1910) 746; (1910) 792; of the township (1910) 1906. It is served by the Delaware & Hudson railway. Cherry Valley is in the centre of a rich farming and dairying district, has a chair factory, and is a summer resort with sulphur and lilia springs. It was the scene of a terrible massacre during the War of Independence. The village was attacked on the 11th of November 1778 by Walter Butler (d. 1781) and Joseph Brant with a force of 800 Indians and Tories, who killed about 50 men, women and children, sacked and burned most of the houses, and carried off more than 70 prisoners, who were subjected to the greatest cruelties and privations, many of them dying or being tomahawked before the Canadian settlements were reached. Cherry Valley was incorporated in 1812.

CHERSIPHON, a Cretan architect, the traditional builder (with his son Metagenes) of the great Ionic temple of Artemis at Ephesus set up by the Greeks in the 6th century. Some remains of this temple were found by J. T. Wood and brought to the British Museum. In connexion with the pillars, which are adorned with archaic reliefs, a fragmentary inscription has been found, recording that they were presented by King Croesus, as indeed Herodotus informs us. This temple was burned on the day on which Alexander the Great was born.

CHERSO, an island in the Adriatic Sea, off the east coast of Istria, from which it is separated by the channel of Farasina. Pop. (1900) 8274. It is situated in the Gulf of Quarnero, and is connected with the island of Lussin, lying on the S.W. by a turn bridge over the small channel of Osseo, and with the island of Veglia, lying on the E. by the Canale di Mezzo. These three are the principal islands of the Quarnaro group, and form together the administrative district of Lussin in the Austrian crownland of Istria. Cherso is an elongated island about 40 m. long, 12 to 70 m. wide, and has an area of 190 sq. m. It is traversed by a range of mountains, which attain in the peak of Syss an altitude of 2000 ft. and form natural terraces, planted with vines and olive trees, specially in the middle and southern parts of the island. The northern part is covered with bushes of laurel.
CHERSONESE—CHERUBIM

and mastic, but there are scarcely any large trees. There is a scarcity of springs, and the houses are generally furnished with cisterns for rain water. In the centre of the island is an interesting lake called the Vrana or Crow's Lake, situated at an altitude of 40 ft. above the level of the sea, 32 m. long, 1 m. wide and 18 ft. deep. This lake is in all probability fed by subterranean sources. The chief town of the island is Cherso, situated on the west coast. It possesses a good harbour and is provided with a shipwright’s wharf.

CHERSONESE, CHERSONESUS, or CHERRONEUS (Gr. χερόνες, dry, and νήσος, island), a word equivalent to “peninsula.” In ancient geography the Chersonesus Thracia, Chersonesus Taurica or Scythica, and Chersonesus Cimbrica correspond to the peninsulas of the Dardanellles, the Crimea and Jutland; and the Golden Chersonese is usually identified with the peninsula of Malaca. The Tauric Chersonese was further distinguished as the Great, in contrast to the Heracleotic or Little Chersonese at its S.W. corner, where Sevastopol now stands.

The Tauric Chersonese1 (from 2nd century A.D. called Cherson) was a Dorian colony of Heraclea in Bithynia, founded in the 5th century B.C. in the midst of the modern Sevastopol. After defending itself against the kingdom of Bosporus (q.v.), and the native Scyths and Tauri, and even extending its power over the west coast of the peninsula, it was compelled to call in the aid of Mithradates VI. and his general Diophantus, c. 110 B.C., and submitted to the Pontic dynasty. On regaining a nominal independence, it came more or less under the Roman suzerainty. In the latter part of the 1st century A.D., and again in the succeeding century, it received a Roman garrison and suffered much interference in its internal affairs. In the time of Constantine, in return for assistance against the Bosporans and the native tribes, it regained its autonomy and received special privileges. It must, however, have been subject to the Byzantine authorities, as inscriptions testify to restorations of its walls by Byzantine officials. Under Theophilus the central government sent out a governor to take the place of the elected magistrate. Even so it seems to have preserved a measure of self-government and may be said to have been the last of the Greek city states. Its ruin was brought about by the commercial rivalry of the Genoese, who forbade the Greeks to trade there and diverted the trade of the Tauri, Caffa and Sudak. Previous to this it had been the main emporium of Byzantine commerce upon the N. coast of the Euxine. Through it went the communications of the empire with the Petcheguas and other native tribes, and more especially with the Russians. The commerce of Cherson is guaranteed in the early treaties between the Greeks and Russians, and it was in Cherson, according to Ps. Nestor’s chronicle, that Vladimir was baptized in 988 after he had captured the city. The constitution of the city was at first democratic under Damiorgi, a senate and a general assembly. Latterly it appears to have become aristocratic, and most of the power was concentrated in the hands of the first archon or Procteon, who in time was superseded by the strategus sent out from Byzantium. Its most interesting political document is the form of oath sworn to by all the citizens in the 3rd century B.C.

The remains of the city occupy a space about two-thirds of a mile long by half a mile broad. They are enclosed by a Byzantine wall. Foundations and considerable remains of a Greek wall going back to the 4th century B.C. have been found beneath this in the eastern or original part of the site. Many Byzantine churches, both cruciform and basilican, have been excavated. The latter survived here into the 13th century when they had long been extinct in other Greek-speaking lands. The churches were adorned with frescoes, wall and floor mosaics, some well preserved, and marble carvings similar to work found at Ravenna. The fact that the site has not been inhabited since the 14th century makes it important for our knowledge of Byzantine life. The city was used by the Romans as a place of banishment: St Clement of Rome was exiled hither and first preached the Gospel; another exile was Justinian II., who is said to have destroyed the city in revenge. We have a considerable series of coins from the 3rd century B.C. to about A.D. 200, and some of Byzantine date.

See B. Koehe, Beiträge zur Geschichte von Chersonesus in Taurien (St Petersburg, 1848); art. “Chersonese” (20) by C. G. Brandis in Pauly-Wissowa, Realencyclopadie, vol. iii. 221; A. A. Bobrinskoy, Chersonesos Taurica (St Petersburg, 1903) (Russian); V. V. Latychev, Inscriptiones, Orae Septentr., Ponti Euxini, vol. i. and iv. Reports of excavations appear in the Compte rendu of the Imperial Archaeological Commission of St Petersburg from 1888 and in its Bulletin. See E. H. Minns, Scythians and Greeks (Cambridge, 1907). (E. H. M.)

CHERTSEY, a market town in the Chertsey parliamentary division of Surrey, England, 22 m. W.S.W. from London by the London & South-Western railway. Pop. of urban district (1901) 12,762. It is pleasantly situated on the right bank of the Thames, which is crossed by a bridge of seven arches, built of Purbeck stone in 1785. The parish church, rebuilt in 1808, contains a tablet to Charles James Fox, who resided at St Anne’s Hill in the vicinity, and another to Lawrence Tomson, a translator of the New Testament in the 17th century. Hardy and remains are left of a great Benedictine abbey, whose buildings in 12th century occupied an area of 4 acres. They fell into almost complete decay in the 13th century, and a “fair house” was erected out of the ruins by Sir Nicholas Carew of Beddington. The ground-plan can be traced; the fish-ponds are complete; and carved stones, coffins and encaustic tiles of a peculiar manufacture are frequently exhumed. Among the abbots the most famous was John de Ruthwyck, who was appointed in 1307, and continued, till his death in 1346, to carry on a great system of alteration and extension, which almost made the abbey a new building. The house in which the poet Cowley spent the last years of his life remains, and the chapel in which he died is preserved unaltered. The town is the centre of a large residential district. Its principal trade is in produce for the London markets.

The first religious settlement in Surrey, a Benedictine abbey, was founded in 666 at Chertsey (Cerelosiac, Ceretsey), the manor of which belonged to the abbey until 1539, since when it has been a possession of the crown. In the reign of Edward the Conessor Chertsey was a large village and was made the head of Godley hundred. The increase of copshold under Abbot John de Ruthwyck led to the founding of the town in 1381 rising and burning the rolls. Chertsey owed its importance primarily to the abbey, but partly to its geographical position. Ferries over the Redwewear were subjects of royal grant in 1340 and 1399; the abbots built a new bridge over the Bourne in 1333, and wholly maintained the bridge over the Thames when it replaced the 14th century ferry. In 1410 the king gave permission to build a bridge over the Redwash. As the centre of an agricultural district the markets of Chertsey were important and are still held. Three days’ fairs were granted to the abbots in 1120 for the feast of St Peter ad Vincula by Henry III. for Holy Rood day; in 1282 for Ascension day; and a market on Mondays was obtained in 1282. In 1590 there were many poor, for whose relief Elizabeth gave a fair for a day in Lent and a market on Thursdays. These fairs still survive.

See Lucy Wheeler, Chertsey Abbey (London, 1905); Victoria County History, Surrey.

CHERUBIM, the Hebrew plural of “cherub” (kərūḇ), imaginary winged animal figures of a sacred character, referred to in the description of Solomon’s temple (1 Kings vi. 23-35, vii. 20, viii. 6, 7), and also in that of the ark of the tabernacle (Ex. xxv. 18-22, xxvi. 1, 31, xxxvii. 7-9). The cherub-images, where such occur, represent to the imagination the supernatural bearers of Yahweh’s throne or chariot, or the guardians of His abode; the cherub-carvings at least symbolize His presence, and communicate some degree of His sanctity. In Gen. iii. 24 the cherubim are the guards of Paradise; Ezek. xxviii. 14, 16 cannot be mentioned here, the text being corrupt. We also find (1 Sam. iv. 4; 2 Sam. vi. 2) as a divine title “that sitteth upon the cherubim”; here it is doubted whether the cherubim are the material ones in the temple, or those which faith assumes and

1 In Pliny “Heraclea Chersonesos,” probably owing to a confusion with the name of the mother city.
the artist tried to represent—the supernatural steeds upon which Yahweh issues forth to interfere in human affairs. In a poetic phrase (Ps. xliii. 10) we find “upon a cherub” parallel to “upon the wings of the wind” (cp. Isa. xix. 1; Ps. civ. 3). One naturally infers from this that the “cherub” was sometimes viewed as a bird. For the clouds, mythologically, are birds. “The Algonkins say that birds always make the winds, that they create the waterspouts, and that the clouds are the spreading and agitation of their wings.” “The Sioux say that the thunder is the sound of the cloud-bird flapping its wings.” If so, Ps. xviii. 10 is a solitary trace of the archaic view of the cherub. The bird, however, was probably a mythic, extra-natural bird. At any rate the cherub was suggested by and represents the storm-cloud, just as the sword in Gen. iii. 24 corresponds to the lightning. In Ezek. i. the four visionary creatures are expressly connected with a storm-wind, and a bright cloud (ver. 4). Elsewhere (xii. 18) the cherub has two faces (a man’s and a bird’s), but in i. 10 and x. 14 each cherub has four faces, a view tastefully simplified in the Johannine Apocalypse (Rev. iv. 7).

It is best, however, to separate Ezekiel from other writers, since he belongs to what may be termed a great mythological revival. Probably his cherubim are a modification of older ones, which may well have been of a more sober type. His own accounts, as we have seen, vary. Probably the cherub has passed through several phases. There was a mythic bird-cherub, and then perhaps a winged animal-form, analogous to the winged figures of bulls and lions with human faces which guarded Babylonian and Assyrian temples and palaces. Another analogy is furnished by the winged genie represented as fertilizing the sacred tree—the date-palm (Tylor); here the body is human, though the face is sometimes that of an eagle. It is perhaps even more noteworthy that figures thought to be cherubs have been found at Zenjirli, within the ancient North Syrian kingdom of Ya’di (see Jeremias, Das Alte Testament im Lichte des Alten Orients, pp. 350 f.); we may combine this with the fact that one of the great gods of this kingdom was called Rakab’el or Rekub’el (also perhaps Rakab or Rekub). A Sabaean (S. Arabian) name Karab’el also exists. The cherubim might perhaps be symbolic representations of the god Rakab’el or Rekub, probably equivalent to Hadad, whose sacred animal was the bull. That the figures symbolic of Rakab or Hadad were compounded or amalgamated by the Israelites with those symbolic of Nergal (the lion-god) and Ninib (the eagle-god), is not surprising.

CHERUBINI, MARIA LUIGI CARLO ZENOBIO SALVATORE (1760–1842), Italian musical composer, was born at Florence on the 14th of September 1760, and died on the 15th of March 1842 in Paris. His father was a companion (Maestro al Cembalo) at the Pergola theatre. Cherubini himself, in the preface of his autograph catalogue of his own works, states, “I began to learn music at six and composition at nine, the former from my father, the latter from Bartolomeo and Alessandro Pellici, and, after their death, from Bizzarri and J Castrucci.” By the time he was 17 he had composed several works of church music, and in 1777 he went to Bologna, where for four years he studied under Sarti. This deservedly masterly man earned the gratitude which afterwards impelled Cherubini to place one of his double choruses by the side of his own Et vitam venturi as the crown of his Treatise on Counterpoint and Fugue, though the juxtaposition is disastrous for Sarti. But besides grounding Cherubini in the church music for which he had early shown so special a bent, Sarti also trained him in dramatic composition; sometimes, like the great masters of painting, entrusting his pupil with minor parts of his own works. From 1780 onwards for the next fourteen years dramatic music occupied Cherubini almost entirely. His first complete opera, Quinto Pablo, was produced in 1780, and was followed in 1782 by Armida, Adriano in Siria, and other works. Between 1782 and 1784 the successful production of five operas in four different towns must have secured Cherubini a dignified position amongst his Italian contemporaries; and in 1784 he was invited to London to produce two works for the Italian opera there, one of which, La Finta Principessa, was favourably received, while the other, Gli eliso Sabino, was, according to a contemporary witness, “murdered” by the critics.

In 1786 he left London for Paris, which became his home after a visit to Turin in 1787–1788 on the occasion of the production there of his Ifigenia in Aulis. With Cherubini, as with some other composers first trained in a school where the singer reigned supreme, the influence of the French dramatic sensibility proved decisive, and his first French opera, Démophon (1788), though not a popular success, already marks a departure from the Italian style, which Cherubini still cultivated in the pieces he introduced into the works of Anfossi, Paisiello and Cimarosa, produced by him as director of the Italian opera in Paris (established in 1786). As in Paris Gluck realized his highest ambitions, and even Rossini awoke to a final effort of something like dramatic life in Guillaume Tell, so in Paris Cherubini became a great composer. If his melodic invention had been as warm as Gluck’s, his immensely superior technique in every branch of his art would have made him one of the greatest composers that ever lived. But his personal character showing in quite a moderation the same asceticism that in less sour and more negative form deprives even his finest music of the glow of that lofty inspiration that furs nothing.

With Lodovica (1793) the series of Cherubini’s masterpieces begins, and by the production of Médée (1797) his reputation was firmly established. The success of this sombre classical tragedy, which shows Cherubini’s genius in its full power, is an honour to the Paris public. If Cherubini had known how to combine his ideals with an urbane tolerance of the opinions of persons of inferior taste, the severity of his music would not have prevented his attaining the height of prosperity. But Napoleon Bonaparte irritated him by an enthusiasm for the kind of Italian music against which his whole career, from the time he became Sarri’s pupil, was a protest. When Cherubini said to Napoleon, “Citoyen Général, I perceive that you love only that music which does not prevent you thinking of your politics,” he may perhaps have been as firm convinced of his own declamatory manner as he was when many years afterwards he “spared the feelings” of a musical candidate by “delicately” telling him that he had “a beautiful voice and great musical intelligence, but was too ugly for a public singer.” Napoleon seems to have disliked opposition in music as in other matters, and the academic offices held by Cherubini under him were for many years far below his deserts. But though Napoleon saw no reason to conceal his dislike of Cherubini, his appointment of Lesueur in 1804 as his chapel-master must not be taken as an evidence of his hostility. Lesueur was not a great genius, but, although recommended for the post by the retiring chapel-master, Paisiello (one of Napoleon’s Italian favourites), he was a very meritorious and earnest Frenchman whom the appointment saved from starvation. Cherubini’s creative genius was never more brilliant than at this period, as the wonderful two-act ballet, Anacreon, shows; but his temper and spirits were not improved by a series of disappointments which culminated in the collapse of his prospects of communal success in Vienna, where he went in 1805 in compliance with an invitation to compose an opera for the Imperial theatre. Here he produced, under the title of Der Wasserträger, the great work which, on its first production on the 7th of January 1805 (26 Növebre, An 8) as Les Deux Jourées, had thrilled Paris with the accents of a humanity restored to health and peace. It was by this time an established favourite in Austria. On the 25th of February Cherubini produced Paniska, but the war between Austria and France had broken out immediately after his arrival, and public interest in artistic matters was checked by the bombardment and capitulation of Vienna. Though the meeting between Cherubini and the victorious Napoleon was not very friendly, he was called upon to direct the music at Napoleon’s soirées at Schönbrunn. But this had not been his object in coming to Vienna, and he soon returned to a retired and gloomy life in Paris.
His stay at Vienna is memorable for his intercourse with Beethoven, who had a profound admiration for him which he could neither realize nor reciprocate. It is too much to expect that the mighty genius of Beethoven, which broke through all rules in vindication of the principles underlying them, would be comprehensible to a mind like Cherubini's, in which, while the creative faculties were finely developed, the critical faculty was atrophied and its place supplied by a mere disciplinary code inadequate even as a basis for the analysis of his own works. On the other hand, it would be impossible to exaggerate the influence Les Deux Journées had on the lighter parts of Beethoven's Fidelio. Cherubini's librettist was also the author of the libretto from which Fidelio was adapted, and Cherubini's score was a constant object of Beethoven's study, not only before the production of the first version of Fidelio as Leonore, but also throughout Beethoven's life. Cherubini's record of his impressions of Beethoven as a man is contained in the single phrase, "Il était toujours brusque," which at least shows a fine freedom from self-consciousness on the part of the man whose only remark on being told of the death of Brod, the famous obilist, was, "Ah, il n'avait pas le chic ton" ("he didn't have much tone"). Of the overture to Leonore Cherubini only remarked that he could not tell what key it was in, and of Beethoven's later style he observed, "It makes me sneeze." Beethoven's brusqueness, notorious as it was, did not prevent him from assuring Cherubini that he considered him the greatest composer of the age and that he loved him and honoured him. In 1806 Haydn had just sent out his pathetic "visiting card" announcing that he was past work; Weber was still sowing wild oats, and Schubert was only nine years old. We need not, then, be surprised at Beethoven's judgment. And though we must regret that Cherubini's disposition prevented him from understanding Beethoven, it would be by no means true to say that he was uninfluenced at least by the sheer grandeur of the scale which Beethoven had by that time established as the permanent standard for musical art. Grandeur of proportion was, in fact, eminently characteristic of both composers, and the colossal structure of such a movement as the duet Perdites ennemis in Molière's Le Malade imaginaire, is almost inconceivable without the example of Beethoven's C minor trio, op. 1, No. 3, published two years before it; while the cavatina Eterno idillo in Faniuka is not only worthy of Beethoven but surprisingly like him in style.

After Cherubini's disappointing visit to Vienna he divided his time between teaching at the conservatoire and cutting up playing-cards into figures and landscapes, which he framed and placed round the walls of his study. Not until 1809 was he aroused from this morbid indolence. He was staying in retirement at the country seat of the prince de Chimay, and his friends begged him to write some music for the consecration of a church there. After persistent refusals he suddenly surprised them with a mass in F for three-part chorus and orchestra. With this work the period of his great church music may be said to begin; although it was by no means the end of his career as an opera writer, which, in fact, lasted as late as his seventy-third year. This third period is also marked by some not unimportant instrumental compositions. An early event in the annals of the Philharmonic Society was his invitation to London in 1815 to produce a symphony, an overture and a vocal piece. The symphony (in D) was afterwards arranged with a new slow movement as the string quartet in C (1829), a fact which, taken in connexion with the large scale of the work, illustrates Cherubini's deficient sense of style in chamber music. Nevertheless all the six string quartets written between 1814 and 1837 are interesting works performed with success at the present day, though the last three, discovered in 1889, are less satisfactory than the earlier ones. The requiem in C minor (1817) caused Beethoven to declare that if he himself ever wrote a requiem Cherubini's would be his model.

At the eleventh hour Cherubini received recognition from Napoleon, who, during the Hundred Days, made him chevalier of the Legion of Honour. Then, with the restoration of the Bourbons, the very fact that Cherubini had not been persona grata with Napoleon brought him honour and emoluments. He was appointed, jointly with Lesueur, as composer and conductor to the Chapel Royal, and in 1822 he obtained the permanent directorship of the conservatoire. This brought him into contact, for the most part unfriendly, with all the most talented musicians of the younger generation. It is improbable that Berlioz would have been an easy subject for the wisest and kindest of spiritual guides; but no influence, repellent or attractive, could have been more disastrous for that passionate, quick-witted and yet eminently puzzle-headed mixture of Philistine and genius, than the crabbed old martinet whose regulations forbade the students access to Gluck's scores in the library, and whose only theory of art (as distinguished from his practice) is accurately formulated in the following passage from Berlioz's Grande Traité de l'instrumentation et d'orchestration:

"It was no use for the modern composer to say, 'But do just listen! See how smoothly this is introduced, how well motivated, how deftly connected with the context, and how splendid it sounds!' He was answered, 'That is not the point. This modulation is forbidden; therefore it must not be made.'"

The lack of really educative teaching, and the actual injustice of Cherubini's disciplinary methods were answerable, did much to weaken Berlioz's at best ill-balanced artistic sense, and it is highly probable that, but for the kindliness and comparative wisdom of his composition master, Lesueur, he would have broken down from sheer lack of any influence which could command the respect of an excitable youth starving in the pursuit of a fine art against the violent opposition of his family. Only when Mendelssohn, at the age of seventeen, visited Paris in 1825, did Cherubini startle every one by praising a young composer to his face.

In 1833 Cherubini produced his last work for the stage, Ali Bâbâ, adapted (with new and noisy features which excited Mendelssohn's astonishment) from a manuscript opera, Kenkourgi, written forty years earlier. It is thus, perhaps, not a fair illustration of the vigour of his old age; but the requiem in D minor (for male voices), written in 1836, is one of his greatest works, and, though not actually his last composition, is a worthy close to the long career of an artist of high ideals who, while neither by birth nor temperament a Frenchman, must yet be counted with a few greater foreigners. Gluck, as the glory of French classical music. In this he has left behind his friend and contemporary, Méhul, to whom he dedicated Médée, and who dedicated to him the beautiful Ossianic one-act opera Uathol. The direct results of his teaching at the conservatoire were the steady, though not as yet unhealthy, decline of French opera into a lighter style, under the amiable and modest Boieldieu and the irresponsible and witty Auber; for, as we have seen, Cherubini was quite incapable of making his ideals intelligible by any means more personal than his music; and the crude grammatical rules which he mistook for the eternal principles of his own and of all music had not the smallest use as a safeguard against vulgarity and pretentiousness.

Lest the passage above quoted from Berlioz should be suspected of bias or irrelevance, we cite a few phrases from Cherubini's Treatise on Counterpoint and Fugue, of which, though the letterpress is by his favourite pupil, Halévy, the musical examples and doctrine are beyond suspicion his own. Concerning the 16th note, Cherubini says: "In the general known as the "changing note" (an idiom which to any musical scholar is as natural as "attraction of the relative" is to a Greek scholar), Cherubini remarks, "No tradition gives any reason why the classics thus faultily deviated from the rule." Again, he discusses the use of "suspending" in a series of chords which without them would contain consecutive fifths, and after making all the observations necessary for the rational conclusion that the question whether the fifths are successfully disguised or not depends upon the beauty and force of the suspensions, he merely remarks that "The opinion of the classics appears to me erroneous, notwithstanding that custom has sanctioned it, for, on the principle that the discord is a mere suspension of the chord, it would not affect the nature of the chord. But since
the classics have pronounced judgment we must of course submit." In the whole treatise not one example is given from Palestrina or any other master who handled as a living language what are now the forms of contrapuntal discipline. As a dead language Cherubini brought counterpoint up to date by abandoning the church modes; but in true severity of principle, as in educational stimulus, his treatise shows a deplorable falling off from the standard set a hundred years before in Fux's *Grades ad Parnassum* with its delightful dialogues between master and pupil and its continual appeal to artistic experience. Whatever may have been Cherubini's success in imparting facility and certainty to his light-hearted pupils who established 19th-century French opera as a refuge from the terrors of serious art, there can be no doubt that his career as a teacher did more harm than good. In it the punishment drill of an incompetent schoolmaster was invested with the authority of a great composer, and by it the false antithesis between the "classical" and the "romantic" was erected into a barrier which many critics still find an insuperable obstacle to the understanding of the classical spirit. And yet as a composer Cherubini was no pseudo-classic but a really great artist, whose purity of style, except at rare moments, just failed to express the ideals he never lost sight of, because in his love of those ideals there was too much fear.

His principal works are summarized by Fétis as thirty-two operas, twenty-nine church compositions, four cantatas and several instrumental pieces, but there is a treatise on counterpoint and fugue.

G. Leclair's full scores of the *Recessions* and of *Les Deux Journées* (the latter unfortunately without the dialogue, which, however, is accessible in its fairly good German translation in the *Reclam Bibliothek*), and also of ten opera overtures, are current in the Peters catalogues. Vocal scores of some of the other operas are not difficult to get. The great *Credo* is in the Peters edition, but is becoming scarce. The string quartets are in Payne's *Miniature Scores*. It is very desirable that the operas, from *Démonoph on* onwards, should be republished in full score.

See also E. Bellasis, Cherubini (1874); and an article with personal reminiscences by the composer Ferdinand Hillier, in *Macmillan's Magazine* (1875). A complete catalogue of his compositions (1773-1841) was published by Botrice du Toulon.

CHÉRUEL, PIERRE ADOLPHE (1800-1891), French historian, was born at Rouen on the 17th of January 1800. He was educated at the École Normale Supérieure, and became a fellow (agrégé) in 1830. His early studies were devoted to his native town. His *Histoire de Rouen sous la domination anglaise au XVe siècle* (1840) and *Histoire de Rouen pendant l'époque communale, 1150-1382* (Rouen, 1843-1844), are meritorious productions for a time when the archives were neither inventoried nor classified, and contain useful documents previously unpublished. His theses for the degree of doctor, *De l'administration de Louis XIV d'après les Mémoires inédits d'Olivier d'Ormesson et De Mario Stuarto et Henrico III.* (1840), led him to the study of general history. The former was expanded afterwards under the title *Histoire de l'administration monarquique en France depuis l'avènement de Philippe-Auguste jusqu'à la mort de Louis XIV* (1853), and in 1855 he also published his *Dictionnaire historique des institutions, mœurs et coutumes de la France moderne,* which many editions have appeared. These works may still be consulted for the 17th century, the period over which Chérueil concentrated all his scientific activity. He edited successively the *Journal d'Olivier Lefebre d'Ormesson* (1850-1862), interesting for the history of the parlement of Paris during the minority of Louis XIV; *Lettres du cardinal Mazarin pendant son ministère* (6 vols., 1870-1891), continued by the vicomte G. d'Avenel; and *Mémoires du duc de Saint-Simon,* published for the first time according to the original MSS. (2 editions, 1856-1858 and 1878-1881). To Saint-Simon also he devoted two critical studies, which are acute but not definitive: *Saint-Simon considéré comme historien de Louis XIV* (1863) and *Notice sur la vie et sur les mémoires du duc de Saint-Simon* (1876). The latter may be considered as an introduction to the famous *Mémoires.* Among his later writings may be mentioned the *Histoire de France pendant la minorité de Louis XIV* (4 vols., 1880) and *Histoire de la France sous le ministère de Mazarin* (3 vols., 1882-1883). These two works are valuable for abundance of facts, precision of details, and clear and intelligent arrangement, but are characterized by a slightly rigid style. In their compilation Chérueil used a fair number of unpublished documents. To the student of the second half of the 17th century in France the works of Chérueil are a mine of information. He died in Paris on the 1st of May 1891.

CHERUSCI, an ancient German tribe occupying the basin of the Weser to the north of the Chatti. Together with the other tribes of western Germany they submitted to the Romans in 11-9 B.C., but in A.D. 9 Arminius, one of their princes, rose in revolt, and defeated and slew the Roman general Quintilius Varus with his whole army. Germanicus Caesar made several unsuccessful attempts to bring them into subjection again. By the end of the 1st century the prestige of the Cheruscis had declined through unsuccessful war with the Chatti. Their territory was eventually occupied by the Saxons.

CHESLEDEN, WILLIAM (1688-1752), English surgeon, was born at Somerby, Leicestershire, on the 14th of October 1688. He studied anatomy in London under William Cowper (1666-1709), and in 1713 published his *Anatomy of the Human Body,* which achieved great popularity and was translated into thirteen editions. In 1718 he was appointed an assistant surgeon at St Thomas's hospital (London), becoming full surgeon in the following year, and he was also chosen one of the surgeons to St George's hospital on its foundation in 1733. He retired from St Thomas's in 1738, and died at Bath on the 10th of April 1752. Cheselden is famous for his "lateral operation for the stone," which he first performed in 1727. He also effected a great advance in ophthalmic surgery by his operation of iridectomy, described in 1728, for the treatment of certain forms of blindness by the production of an "artificial pupil." He attended Sir Isaac Newton in his last illness, and was an intimate friend of Alexander Pope and of Sir Hans Sloane.

CHESHAM, a market town in the Aylesbury parliamentary division of Buckinghamshire, England, 26 m. W.N.W. of London by the Metropolitan railway. Pop. of urban district (1901) 7245. It is pleasantly situated in the narrow valley of the river Chess, closely flanked by low wooded hills. The church of St Mary is cruciform and mainly Perpendicular. Some ancient frescoes and numerous monuments are preserved. All sorts of small dairy utensils, chairs, malt-shovels, &c., are made of beech, the growth of which forms a feature of the surrounding country. Shoemaking is also carried on. In Waterside hamlet, adjoining the town, are flour-mills, duck farms, and some of the extensive watercress beds for which the Chess is noted, as it is also for its trout-fishing.

CHESHIRE, a north-western county of England, bounded N. by Lancashire, N.E. by Yorkshire and Derbyshire, S.E. by Staffordshire, S. by Shropshire, W. by Denbighshire and Flint, and N.W. by the Irish Sea. Its area is 1027-8 sq. m. The coast-line is formed by the estuaries of the Dee and the Mersey, which are separated by the low rectangular peninsula of Wirral. The estuary of the Dee is dry at low tide on the Cheshire shore, but the Mersey bears mariners to the ports of Liverpool (in Lancashire) and Birkenhead (on the Wirral). The Dee forms a great part of the county boundary with Denbighshire and Flint, and the Mersey the boundary along the whole of the northern side. The principal river within the county is the Weaver, which crosses it with a north-westerly course, and, being joined by the Dane at Northwich, discharges into the estuary of the Mersey south of Runcorn. The surface of Cheshire is mostly low and gently undulating or flat; but the broken line of the Peckforton hills, seldom exceeding 600 ft. in height, runs north and south flaming the valley of the Weaver on the west. A low narrow gap in these hills is traversed by the small river Gowy, which rises to the east but has the greater part of its course to the west of them. Commanding this gap on the west, the Norman castle of Beeston stands on an isolated eminence. The northern part of the hills coincides approximately with the district still called Delamere Forest, formerly a chase of the earls of Chester, and finally dispossessed in 1812.
**CHESHIRE**

In certain sequestered parts the forest has not wholly lost its ancient character. On the east Cheshire includes the western face of the coal belt of high land which borders on the Peak district of Derbyshire; these hills rise sharply to the east to Congleton, Macclesfield and Hyde, reaching a height of about 1800 ft. within Cheshire. Distributed over the county, but principally in the eastern half, are many small lakes or meres, such as Combermere, Tatton, Rostherne, Tabley, Doddington, Marbury and Mere, and it was a common practice among the gentry of the county to build their mansions on the banks of these waters. The meres form one of the most picturesque features of the county.

**Geology.**—With the exception of a small area of Carboniferous rocks on the eastern border, and a small patch of Lower Lias near Audlem, the whole country is occupied by Triassic strata. The great central plain is covered by till and morainic terrains. From these marls salt is obtained; there are many beds of rock-salt, mostly thin; two are much thicker than the others, being from 75 ft. to over 100 ft. thick. Thin beds and veins of gypsum are common in the marls. The striking features of the Peckforton Hills are the wide lumps of the Lower Lias, which lies upon beds of Bunter Sandstone. Besides forming this well-marked ridge, the Lower Keuper Sandstones or “Waterstones” form several ridges north-west of Macclesfield and appear along most of the eastern borders of the county. The Lower Lias forms the cliffs of New Brighton and Birkenhead. The Lower Keuper Sandstone is quarried near the last-named place, also at Stretton, Delamere and Manley. This is a good building stone and an important water-bearing formation. The rocks are often seen in the fields of the Cheshire and Drink. At Alderley Edge oren of copper, lead and cobalt are found. West of the Peckforton ridge, Bunter Sandstones and pebbly beds extend to the border. They also form low foothills between the Zoological and notice the high Basom Min and neighbouring hills. East of Basom Min, on either side of the Goyt valley, are the Millstone Grits and Shales, forming the easterly moorland tracts. Cloud Hill, a striking feature near Congleton, is capped by the “Third Grit,” one of the Millstone Grits. The Pennard Moraine and its extension, the Pendleside series. These rocks extend from Congleton Edge near Macclesfield, where the outcrop bends sharply eastward and runs up the Goyt valley. Some hard quartzites in the Pendleside series, known locally as “Chorltonstones,” have contributed to the formation of the high Basom Min and neighbouring hills. Climate and Agriculture.—The climate is temperate and rather damp; the soil is varied and irregular, but a large proportion is a thin-skinned clay. More than four-fifths of the total area is under cultivation. The crop of wheat is comparatively insignificant, but a large quantity of oats is grown, and a great proportion of the cultivated land is in permanent pasture. The vicinity of such populous centres as Liverpool and Manchester, as well as the several large towns within the county, makes cattle and dairy-farming profitable. Cheese of excellent quality is produced, the name of the county being given to a particular brand (see Dairy). Potatoes are by far the most important green crop. Fruit-growing is carried on in some parts, especially the cultivation of stone fruit and, among these, damsons; while the strawberry beds near Parndon and Holt are celebrated. In the first half of the 19th century the condition of agriculture in Cheshire was notoriously backward; and in 1858-1866 the county suffered with especial severity from a visitation of cattle plague. The prices of stock ascended to more than 66,000 head, and it was necessary to obtain from the Treasury a loan of £70,000 on the security of the county rate, for purposes of relief and compensation. The cheese-making industry naturally received a severe blow, yet to agriculture at large an ultimate good resulted as the possibility and even the necessity of these measures were borne in upon the farmers.

The industries of the county are various and important. The manufacture of cotton goods extends from its seat in Lancashire into Cheshire, at the town of Stockport and elsewhere in the north. Macclesfield and Congleton are centres of silk manufacture. At Crewe are situated the great workshops of the London & North-Western railway company, the institution of which actually brought the town into being. Another instance of the modern creation of a town by an individual industrial corporation is seen in Port Sunlight on the Mersey, where the soap-works of Messrs Lever are situated. On the Mersey there are ship-building yards, and machinery and iron works. Other important manufactures are those of tools, chemicals, clothing and hats, and there are printing, bleaching and dye works, and metal foundries. Much sandstone is quarried, but the mineral wealth of the county lies in coal and salt. The second is a specially important product. Some rock-salt is obtained at Northwich and Winsford, but most of the salt is extracted from brine both here and at Lawton, Wheelock and Middlewich. At Northwich and other places in the locality curious accidents frequently occur owing to the sinking of the soil after the brine is pumped out; walls crack and collapse, and houses are seen leaning far out of the perpendicular. A little copper and lead are found.

**Communications.**—The county is well served with railways. The main line of the London & North-Western railway, passing north from Crewe to Warrington in Lancashire, serves no large town, but from Crewe branches diverge fanwise to Manchester, Chester, North Wales and Shrewsbury. The Great Western railway, with a line coming northward from Wrexham, obtains access through Cheshire to Liverpool and Manchester. These two companies jointly work the Birkenhead railway from Chester to Birkenhead. The heart of the county is traversed by the Cheshire Lines, serving the salt district, and reaching Chester from Manchester by way of Delamere Forest. In the east the Midland and Great Central systems enter the county, and the North Staffordshire line serves Macclesfield. The Manchester, South Junction & Altrincham and the Wirral railways are small systems serving the localities indicated by their names. The river Weaver is locked as far up as Winsford, and the transport of salt is thus expedited. The profits of the navigation, which was formerly undertaken in 1760 by a few Cheshire squires, belong to the county, and are paid annually to the relief of the county rates. In the salt district through which the Weaver passes a subsidy of the land has resulted in the formation of lakes of considerable extent, which act as reservoirs to supply the navigation. There are further means of inland navigation by the Grand Trunk, Shropshire Union and other canals, and many small steamers are in use. The Manchester Ship Canal passes through a section of north Cheshire, being entered from the estuary of the Mersey by locks near Eastham, and following its southern shore up to Runcorn, after which it takes a more direct course than the river.

**Population and Administration.**—The ancient county, which is a county palatine, has an area of 657,783 acres, with a population in 1891 of 730,058 and in 1901 of 815,000. Cheshire has been described as a suburb of Liverpool, Manchester and the Potters of Staffordshire, and many of those whose business lies in these centres have colonized such districts as Bowdon, Alderley, Sale and Marple near Manchester, the Wirral, and Alsager on the Staffordshire border, until these localities have come to resemble the richer suburban districts of London. On the short seacoast of the Wirral are found the popular resorts of New Brighton and Hoylake. This movement and importance of its industries have given the county a vast increase in population, which act as reservoirs to supply the navigation. In 1881 the population was 651,201; from 1891 until that year it had increased 101%. The area of the administrative county is 654,823 acres. The county contains 7 hundreds. The municipal boroughs are Birkenhead (pop. 110,915), Chester (38,909), Congleton (10,707), Crewe (42,074), Dukinfield (18,920), Hyde (32,766), Macclesfield (34,624), Stalybridge (27,673), Stockport (92,832). Chester, the county town, is a city, county of a city, and county borough, and Birkenhead and Stockport are county
broughs. The other urban districts with their populations are as follows:

</table>

Of the townships in this table, those marked (a) are within a radius of about 15 m. from Manchester (Knutsford being taken as the limit). While those marked (b) are in the Wirral. The localities of densest population are thus clearly illustrated.

The county is in the North Wales and Chester circuit, and assizes are held at Chester. It has one court of quarter sessions, and is divided into fourteen petty sessionsal divisions. The county is wholly diocesan, excepting Daresbury, and has separate commissions of the peace, and Birkenhead and Chester have separate courts of quarter sessions. There are 464 civil parishes. Cheshire is almost wholly in the diocese of Chester, but small parts are in those of Manchester, St Asaph and Lichfield. There are 268 ecclesiastical parishes or districts wholly or in part within the county. There are eight parliamentary divisions, namely, Macclesfield, Crewe, Eddisbury, Wirral, Knutsford, Altrincham, Hyde and Northwich, each returning one member; the county also includes the parliamentary borough of Birkenhead returning one member, and parts of the borough of Stockport, which returns two members, and of Ashton-under-Lyne, Chester, Stalybridge, and Warrington, which return one member each.

**History.**—The earliest recorded historical fact relating to the district which is now Cheshire is the capture of Chester and destruction of the native Britons by the Northumbrian king Ethelfrith about 614. After a period of incessant strife between the Britons and their Saxon invaders the district was subjugated by Egbert in 850 and incorporated in the kingdom of Mercia. D'Ivor, the king's son, strengthened the border fortress of Chester, and received the homage of his tributary kings from Berwick to Kent, and in the 10th century Ethelfred rebuilt the city, and erected fortresses at Eddisbury and Runcorn. Edward the Elder garrisoned Thelwall and strengthened the passages of the Mersey and the Irwell. On the splitting up of Mercia in the 10th century the dependent districts along the Dee were made a shire for the fortress of Chester. The shire is first mentioned in the Abingdon Chronicle, which relates that in 980 Cheshire was plundered by a fleet of Northmen. At the time of the Domesday Survey the county was divided into twelve hundreds, exclusive of the six hundreds between the Ribble and the Mersey, now included in Lancashire, but then a part of Cheshire. These divisions have suffered great modification, both in extent and in name, and of the seven modern hundreds Bucklow alone retains its Domesday appellation. The hundreds of Atcham and Exestan have been transferred to the counties of Flint and Denbigh, with the exception of a few townships now in the hundred of Broxton. The prolonged resistance of Cheshire to the Conqueror was punished by ruthless harrying and sweeping confiscations of property, and no Englishman retained estates of importance after the Conquest. In order that the shire might be relieved of all obligations beyond the ever-growing necessity of defending its borders against the inroads of hostile neighbours, it was constituted a county palatine which the earl of Chester "held as freely by his sword as the king held England by his crown." The county had its independent parliament consisting of the barons and clergy, and courts, and all lands except those of the bishop were held of the earl. The court of exchequer was presided over by a chamberlain, a vice-chamberlain, and a baron of the exchequer. It was principally a court of revenue, but probably a court of justice also, before that of the justiciary was established, and had besides the functions of a chancery court, with an exclusive jurisdiction in equity. Other officers of the palatine were the constable, high-steward and the serjeants of the peace and of the forests. The abbots of St Werburgh and Combermere and all the eight barons held courts, in any of which cases of capital felony might be tried.

During the 12th and 13th centuries the county was impoverished by the constant inroads of the Welsh. In 1264 the castle and city of Chester were granted to Simon de Montfort, and in 1267 the treaty of Shrewsbury procured a short interval of peace. Richard II., in return for the loyal support furnished him by the county, made it a principality, but the act was revoked in the subsequent reign. In 1463 Cheshire was the headquarters of Hashopur, who roused the people by telling them that Richard II. was still living. At the beginning of the Wars of the Roses Margaret collected a body of supporters from among the Cheshire gentry, and the English rising occurred late in 1464. At the time of the Civil War feeling was so equally divided that an attempt was made to form an association for preserving internal peace. In 1643, however, Chester was made the headquarters of the royalist forces, while Nantwich was garrisoned for the parliament, and the county became the scene of constant skirmishes until the surrender of Chester in 1646 put an end to the struggle.

From the number of great families with which it has been associated Chester has been named "the mother and nurse of English gentility." Of the eight baronies of the earldom none survives, but the title of that of Kinderton was bestowed in 1762 on George Venables-Vernon, son of Anne, sister of Peter Venables, last baron of Kinderton, from whom the present Lord Vernon of Kinderton is descended. Other great Domesday proprietors were Anthony Fitzgerald, lord of Halton, ancestor of the Lacy's; Hugh de Mara, baron of Montalt, ancestor of the Ardens; Ranulph, ancestor of the Mainwaring's; and Hamo de Massy. The Davenport's, Leighs and Warburtons trace their descent back to the 12th century, and the Grosvenors are descended from another branch of Davenport's. In the reign of Henry VIII. the distinctive privileges of Cheshire as a county palatine were considerably abridged. The right of sanctuary attached to the city of Chester was abolished; justices of the peace were appointed as in other parts of the kingdom, and in 1542 it was enacted that in future two knights for the shire and two burgesses for the city of Chester should be returned to parliament. After the Reform Act of 1832 the county returned four members from two divisions, and Macclesfield and Stockport returned two members each. Birkenhead secured representation in 1835. From 1868 until the Redistribution Act of 1885 the county returned six members from three divisions.

From earliest times the staple products of Cheshire have been salt and cheese. The salt-pits of Nantwich, Middlewich and Northwich were in active operation at the time of Edward the Confessor, and at that date the mills and fisheries on the Dee also furnished a valuable source of revenue. Twelfth century writers refer to the excellence of Cheshire cheese, and at the time of the Civil War three hundred tons at £3 3s. 4d. were ordered in one year for the troops in Scotland. The trades of tanners, skinners and glove-makers existed at the time of the Conquest, and the export trade in wool in the 13th and 14th centuries was considerable. The first bed of rock-salt was discovered in 1670. Weaving and wool-combing were introduced in 1674.

**Antiquities.**—The main interest in the architecture of the...
CHESHUNT—CHESNEY, C. C.

county lies in the direction of domestic buildings rather than ecclesiastical. Old half-timbered houses are common in almost every part of the county; many of these add to the picturesque ness of the modern town and the old market town. Cheshunt, in the county of Hertford, is an ancient market town, the original town of the same name, and was the residence of Richard Cromwell the Protector after his resignation. The town has been in existence since at least the 13th century, but the original town was acquired by William Cecil, Lord Burghley, in 1561; being taken in 1607 by James I. from Robert Cecil, first earl of Salisbury, in exchange for Hatfield House. The town is situated on the River Lea, and is about 22 miles from London by rail, and about 50 miles from the North Sea coast. It is a market town, and has a population of about 12,000. The town is divided into two parts, Cheshunt and Chelmsford, and is bounded on the north by the River Lea, and on the south by the River Blackwater.

CHESNEY, an urban district in the Hertford parliamentary division of Hertfordshire, England, on the Lea, 14 m. N. of London by the Great Eastern railway. Pop. (1891) 6200; (1901) 12,292. The church of St Mary is Perpendicular and has been enlarged in modern times. A college was founded, for the education of young men to the ministry of the Connexion, by Selina countess of Huntingdon in 1678 at Trevecca-isaf near Talgarth, Breconshire. In 1792 it was moved to Cheshunt, and became known as Cheshunt College. In 1804, it was felt that the college was unable properly to carry on its work under existing conditions, it was proposed to amalgamate it with Hackney College, but the Board of Education refused to sanction any arrangement which would set aside the requirements of the deed of foundation, namely that the officers and students of Cheshunt College should subscribe the fifteen articles appended to the deed, and should take certain other obligations. In 1865 it was decided by the board to reorganize the college and remove it to Cambridge.

Nursery and market gardening, largely under glass, brick-making and saw-mills are the chief industries of Cheshunt. Roman coins and other remains have been found at this place, and an urn appears built into the wall of an inn.

British village or small town is indicated. There was a Benedictine nunnery here in the 13th century. Of several interesting ruins was the monastery of the Great House, a residence of Cardinal Wolsey, and a former Pengelly House was the residence of Sir Edward Hamley in the corresponding chair at the Staff College. The writings of these two brilliant officers had a great influence not only at home, but on the continent and in America. Chesney's
first published work (1863) was an account of the Civil War in Virginia, which went through several editions. But the work which attained the greatest reputation was his Water Lily Lectures (1868), prepared from the notes of lectures orally delivered at the Staff College. Up to that time the English literature on the Waterloo campaign, although voluminous, was made up of personal reminiscences or of formal records, useful materials for history rather than history itself; and the French accounts had mainly taken the form of fiction. In Chesney's lucid and vigorous account of the momentous struggle, while it illustrates both the strategy and tactics which culminated in the final catastrophe, the mistakes committed by Napoleon are laid bare, and for the first time an English writer is found to point out that the dispositions of Wellington were far from faultless. And in the Water Lily Lectures the Prussians are for the first time credited by an English pen with their proper share in the victory. The work attracted much attention abroad as well as at home, and French and German translations were published.

Chesney was for many years a constant contributor to the newspaper press and to periodic literature, devoting himself for the most part to the critical treatment of military operations, and professional subjects generally. Some of his essays on military biography, contributed mainly to the Edinburgh Review, were afterwards published separately (1874). In 1868 he was appointed a member of the royal commission on military education, under the presidency first of Earl De Grey and afterwards of Lord Dufferin, to whose recommendations were due the improved organization of the military colleges, and the development of military education in the principal military stations of the British army. In 1871, on the conclusion of the Franco-German War, he was sent on a special mission to France and Germany, and furnished to the government a series of valuable reports on the different siege operations which had been carried out during the war, especially the two sieges of Paris. These reports were published in a large volume, which was issued confidentially. Never seeking regimental or staff preferment, Colonel Chesney never obtained any, but he held at the time of his death a unique position in the army, which had been his actual place in it. He was consulted by officers of all grades on professional matters, and few have done more to raise the intellectual standard of the British officer. Constantly engaged in literary pursuits, he was nevertheless laborious and exemplary in the discharge of his public duties, while managing also to devote a large part of his time to charitable and religious offices. He was abstemious to a fault; and, overwork of mind and body tending at last on a frail constitution, he died after a short illness on the 19th of March 1876. He had become lieutenant-colonel in 1873, and at the time of his death he was commanding Royal Engineer of the London district. He was buried at Sandhurst.

CHESNEY, FRANCIS RAWDON (1789–1872), British general and explorer, was the son of Captain Alexander Chesney, an Irishman of Scottish descent who, having emigrated to South Carolina in 1777, did brilliant service under Lord Rawdon (afterwards marquess of Hastings) in the War of Independence, and subsequently received an appointment as coast officer at Annalong, Co. Down, Ireland. There F. R. Chesney was born on the 16th of March 1789. Lord Rawdon gave the boy a cadetship at Woolwich, and he was gazetted to the Royal Artillery in 1803. But though he rose to be lieutenant-general and colonel-commandant of the 14th brigade Royal Artillery (1864), and general in 1868, Chesney's memory lives not for his military record, but for his connexion with the Suez Canal, and with the exploration of the Euphrates valley, which started with his being sent out to Constantinople in the course of his military duties in 1829, and his making a tour of inspection in Egypt and Syria. His report in 1830 on the feasibility of making the Suez Canal was the original basis of Lesseps' great undertaking (in 1869 Lesseps greeted him in Paris as the "father" of the canal); and in 1831 he introduced to the home government the idea of opening a new overland route to India, by a daring and adventurous journey (for the Arabs were hostile and he was ignorant of the language) along the Euphrates valley from Anah to the Persian Gulf. Returning home, Colonel Chesney (as he then was) busied himself to the supreme of 1883, for which the East India Company's board was favourable; and in 1835 he was sent out in command of a small expedition, for which parliament voted £20,000, in order to test the navigability of the Euphrates. After encountering immense difficulties, from the opposition of the Egyptian pasha, and from the need of transporting two steamers (one of which was lost) in sections from the Mediterranean over the hilly country to the river, they successfully arrived by water at Bushire in the summer of 1836, and proved Chesney's view to be a practicable one. In the middle of 1837 he returned to England, and was given the Royal Geographical Society's gold medal, having meanwhile been to India to consult the authorities there; but the preparation of his two volumes on the expedition (published in 1850) was interrupted by his being ordered out in 1843 to command the artillery at Hong Kong. In 1847 his period of service was completed, and he went home to Ireland, to a life of retirement; but both in 1856 and again in 1862 he went out to the East to take a part in surveys and negotiations for the Euphrates valley railway scheme, which, however, the government would not take up, in spite of a favourable report from the House of Commons committee in 1871. In 1868 he published a further volume of narrative on his Euphrates expedition. He died on the 30th of January 1872.

CHESNEY, SIR GEORGE TOMKINS (1830–1895), English general, brother of Colonel C. C. Chesney, was born at Tiverton, Devonshire, on the 30th of April 1830. Educated at Blundell's school, Tiverton, and at Addiscombe, he entered the Bengal Engineers as second lieutenant in 1848. He was employed for some years in the public works department and, on the outbreak of the Indian Mutiny in 1857, joined the Ambala column, was field engineer at the battle of Badli-ke-serai, brigade-major of engineers throughout the siege of Delhi, and was severely wounded in the assault (medal and clasp and a brevet major). In 1861 he was appointed head of a new department in connexion with the public works accounts. His work on Indian Polity (1868), dealing with the administration of the several departments of the Indian government, attracted wide attention and remains a permanent text-book. The originator of the Royal Indian Civil Engineering College at Cooper's Hill, Staines, he was also its first president (1871–1880). In 1871 he contributed to Blackwood's Magazine, "The Battle of Dorking," a vivid account of a supposed invasion of England by the Germans after their victory over France. This was republished in many editions and translations, and produced a profound impression. He was promoted lieutenant-colonel, 1869; colonel, 1877; major-general, 1886; lieutenant-general, 1887; colonel-com- mandant of Royal Engineers, 1890; and general, 1892. From 1881 to 1886 he was secretary to the military department of the government of India, and was made a C.S.I. and a C.I.E. From 1886 to 1892, as military member of the governor-general's council, he carried out many much-needed military reforms. He was made a C.H. in 1892 and was appointed to the K.G., C.B. on the 1st of January 1892. In 1892 he was appointed aide-de-camp to His Majesty the Emir of Kuwait. In that year he was returned to parliament in the Conservative interest, as member for Oxford, and was chairman of the committee of service members of the House of Commons until his death on the 31st of March 1895. He wrote some novels, The Dilemma, The Private Secretary, The Lesters, &c., and was a frequent contributor to periodical literature.

CHESS, once known as "checker," a game played with certain pieces on a special board described below. It takes its name from the Persian word shah, a king, the name of one of the pieces or men used in the game. Chess is the most cosmopolitan of all games, invented in the East (see History, below), introduced into the West and now domiciled in every part of the world. As a mere pastime chess is easily learnt, and a very moderate amount of study enables a man to become a fair player, but the higher ranges of chess-skills are only attained by persistent labour. The real proficient or master not merely must know...
the subtle variations in which the game abounds, but must be able to apply his knowledge in the face of the enemy and to call to his aid, as occasion demands, all that he has of foresight, brilliancy and resource, both in attack and in defence. Two chess players fighting over the board may fitly be compared to two famous generals encountering each other on the battlefield, the strategy and the tactics being not dissimilar in spirit.

The Board, Pieces and Moves.—The chessboard is divided (see accompanying diagrams) into sixty-four chequered squares. In diagram 1, the pieces, or chess-men, are arranged for the beginning of a game, while diagram 2 shows the denomination of the squares according to the English and German systems of notation. Under diagram 1 are the names of the various "pieces"—each side, White or Black, having a King, a Queen, two Rooks (or Castles), two Knights, and two Bishops. The eight men in front are called Pawns. At the beginning of the game the queen always stands upon a square of her own colour. The board is so set that each player has a white square at the right hand end of the row nearest to him. The rook, knight and bishop on the right of the king are known as King's rook, King's knight, and King's bishop; the other three as Queen's rook, Queen's knight, and Queen's bishop.

Briefly described, the powers of the various pieces and of the pawns are as follows.

The king may move in any direction, only one square at a time, except in castling. Two kings can never be on adjacent squares.

The queen moves in any direction square or diagonal, whether forward or backward. There is no limit to her range over vacant squares; an opponent she may take; a piece of her own colour stops her. She is the most powerful piece on the board, for her action is a menace of those of the rook and bishop. The rooks (from the Indian rukh and Persian rookh, meaning a soldier or warrior) move in straight lines—forward or backward—but they cannot move diagonally. Their range is like the queen's, unlimited, with the same exceptions.

The bishops move diagonally in any direction whether backward or forward. They have an unlimited range, with the same exceptions.

The knights' moves are of an absolutely different kind. They move from one corner of any rectangle of three squares by two to the opposite corner; thus, in diagram 3, the white knight can move to the square occupied by the black one, and vice versa, or a knight could move from C to D, or D to C. The move may be made in any direction. It is no obstacle to the knight's move if squares A and B are occupied. It will be perceived that the knight always moves to a square of a different colour.

The king, queen, rooks and bishops may capture any foe on which stands anywhere within their respective ranges; and the knights can capture the adverse men which stand upon the squares to which they can leap. The piece which takes occupies the square of the piece which is taken, the latter being removed from the board. The king cannot capture any man which is protected by another man.

The moves and capturing powers of the pawns are as follows:—Each pawn for his first move may advance either one or two squares straight forward, but afterwards one square only, and this whether upon starting he exercised his privilege of moving two squares or not. A pawn can never move backwards. He can capture only diagonally—one square to his right or left front. A pawn moves like a rook, captures like a bishop, but only one square at a time. When a pawn arrives at an eighth square, viz. at the extreme limit of the board, he may, at the option of his owner, be exchanged for any other piece, so that a player may, e.g., have two or more queens on the board at once.

"Check and Checkmate." The king can never be captured, but when any piece or pawn attacks him, he is said to be "in check," and the fact of his being so attacked should be announced by the adverse player saying "check," whereupon the king must move from the square he occupies, or be screened from check by the interposition of one of his own men, or the attacking piece must be captured. If, however, when the king is in check, none of these things can be done, it is "checkmate" (Persian, shah mat, the king is dead), known generally as "mate," whereupon the game terminates, the party whose king has been thus checkmated being the loser. When the adversary has only his king left, it is very easy to checkmate him with only a queen and king, or only a rook and king. The problem is less easy with king and two bishops, and still less easy with king, knight and bishop, in which case the opposing king has to be driven into a corner square whose colour corresponds with the bishop's, being given with the bishop. A king and two knights cannot mate. To mate with king and rook the opposing king must be driven on to one of the four side files and kept there with the rook on the next file, till it is held by the other king, when the rook mates.

The pawn gives check in the same way as he captures, viz. diagonally. One king cannot give check to another, nor may a king be moved into check.

"Check by discovery" is given when a player, by moving one of his pieces, checks with another of them. "Double check" means attacking the king at once with two pieces—one of the pieces in this case giving check by discovery.

"Perpetual check" occurs when one player, seeing that he cannot win the game, finds the men so placed that he can give check ad infinitum, while his adversary cannot possibly avoid it. The game is then drawn. A game is also drawn "if, before touching a man, the player whose turn it is to play, claims that the game be treated as drawn, and proves that the existing position existed, in the game and at the commencement of his turn of play, twice at least before the present turn."

"Stalemate." When a king is not in check, but his owner has no move left save such as would place the king in check, it is "stalemate," and the game is drawn.

"Castling." This is a special move permitted to the king once only in the game. It is performed in combination with either rook, the king being moved two squares laterally, while the rook towards which he is moved (which must not have previously
moved from its square) is placed next him on the other side; the king must be touched first. The king cannot castle after having been moved, nor when any piece stands between him and the rook, nor if he is in check, nor when he has to cross a square commanded by an adverse piece or pawn, nor into check. It will be perceived that after casting with the king's rook the latter will occupy the KB square, while the king stands on the KKt square, and if with the queen's rook, the latter will occupy the queen's square while the king stands on the QB square.

"Taking en passant." This is a privilege possessed by any of the pawns under the following circumstances:—If a pawn, say of the white colour, stands upon a fifth square, say upon K5 counting from the white side, and a black pawn moves from Q2 or KB2 to Q4 or KB4 counting from the black side, the white pawn can take the black pawn en passant. For the purposes of such capture the latter is dealt with as though he had only moved to Q3 or KB3, and the white pawn taking him diagonally then occupies the square the captured pawn would have reached had he moved but one square. The capture can be made only on the move immediately succeeding that of the pawn to be captured.

"Drawn Game." This arises from a stalemate (noticed above) from either player not having sufficient force where with to effect checkmate, as when there are only two kings left on the board, or king and bishop against king, or king with one knight, or two knights against king, or from perpetual check. One of the players can call upon the other to give checkmate in fifty moves, the result of failure being that the game is drawn. But, if a pawn is moved, or a piece is captured, the counting must begin again.

A "minor piece" means either a knight or a bishop. "Winning the exchange" signifies capturing a rook in exchange for a minor piece. A "passed pawn" is one that has no adverse pawn either in front of or on either of the adjoining files. A "file" is simply a line of squares extending vertically from one end of the board to the other. An "open file" is one on which no piece or pawn of either colour is standing. A pawn or piece is en prise when one of the enemy's men can capture it. "Gambit" is a word derived from the Ital. gambello, a tripping up of the heels; it is a term used to signify an opening in which a pawn or piece is sacrificed at the opening of a game to obtain an attack. An "opening," or "debut," is a certain set method of commencing a game. When a player can only make one legal move, that move is called a "forced move."

Value of the Pieces.—The relative worth of the chess-men cannot be definitely stated on account of the increase or decrease of their powers according to the position of the game and the pieces, but taking the pawn as the unit the following will be an estimate near enough for practical purposes:—pawn 1, bishop 3 or 4, knight 3 or 2, rook 5 or 6. Three minor pieces may more often than not be advantageously exchanged for the queen. The knight is generally stronger than the bishop in the end game, but two bishops are usually stronger than two knights, more especially in open positions.

 Laws.—The laws of chess differ, although not very materially, in different countries. Various steps have been taken, but as yet without success, to secure the adoption of a universal code. In competitions among English players the particular laws to be observed are specially agreed upon,—the regulations most generally adopted being those laid down at length in Staunton's Chess Praxis, or the modification of the Praxis laws issued in the name of the British Chess Association in 1862.

First Move and Move.—To decide who moves first, one player conceals a white pawn in one hand and a black pawn in the other, his adversary not seeing in which hand the different pawns are put. The other holds out his hands with the pawns concealed, and his adversary touches one. If that contains the white pawn, he takes the white men and moves first. If he draws the black pawn his adversary has the first move, since white, by convention, always plays first. Subsequently the first move is taken alternately. If one player, by way of odds, "gives" his adversary a pawn or piece, that piece is removed before play begins.

the odds are "pawn and move," or "pawn and two," a black pawn, namely, the king's bishop's pawn, is removed and white plays one move, or any two moves in succession. "Pawn and two" is generally considered to be slightly less in point of odds than to give a knight or a bishop; to give a knight and a bishop is to give rather more than a rook; a rook and bishop less than a queen; two rooks rather more than a queen. The odds of the "marked pawn" can only be given to a much weaker player. A pawn, generally KB's pawn, is marked with a cap of paper. If the pawn is captured its owner loses the game; he can also lose by being checkmated in the usual way, but he cannot give mate to his adversary with any man except the marked pawn, which may not be moved to an eighth square and exchanged for a piece.

Rules.—If a player touch one of his men he must move it, unless he says j'adoube (I adjourn), or words of a similar meaning, to the effect that he was only settling it straight on its square. If he cannot legally move a touched piece, he must move his king, if he can, but may not castle; if not, there is no penalty. He must say j'adoube before touching his piece. If a player touch an opponent's piece, he must take it, if he can: if not, move his king. If he can do neither, no penalty. A move is one where the intended move can be taken back, as soon as a player, having moved a piece, has taken his hand off it. If a player is called upon to mate under the fifty-move rule, "fifty moves" means fifty moves and the forty-nine replies to them. A pawn that reaches an eighth square must be exchanged for some other piece, the move not being complete until this is done; a second king cannot be selected.

Modes of Notation.—The English and German methods of describing the moves made in a game are different. According to the English method each player counts from his own side of the board, and the moves are denoted by the names of the files and the numbers of the squares. Thus when a player for his first move advances the king's pawn two squares, it is described as follows:—"1. P—Q4." The following moves, with the aid of diagram 2, will enable the reader to understand the principles of the British notation. The symbol X is used to express "takes"; a dash - to express "to."

1. P—K4 1. P—K4
2. KQt—KB3 2. QKt—QB3
(i.e. King's Knight to the (i.e. Queen's Knight to the
third square of the King's third square of the Queen's
Bishop's file) Bishop's file)
3. KB—QB4 3. KB—QB4
(Queen's Bishop to the fourth square of the (Queen's
Queen's Bishop's file) Bishop's file)
4. P—QB3 4. KQt—KB3
5. P—Q4 5. P takes P (or P×P)
(Queen's Bishop's pawn (King's pawn takes White's
takes pawn: no other pawn Queen's pawn)
has a pawn en prise)
6. KB—QKt5 (ch., i.e. check)

It is now usual to express the notation as concisely as possible; thus, the third moves of White and Black would be given as 3. B—B4, because it is clear that only the fourth square of the queen's bishop's file is intended.

The French names for the pieces are, King, Roi; Queen, Dame; Rook, Tour; Knight, Cavalier; Pawn, Pion; for Bishop the French substitute Fou, a jester. Chess is Les Echecs.

The German notation employs the alphabetical characters a, b, c, d, e, f, g and h, proceeding from left to right, and the numerals 1, 2, 3, 4, 5, 6, 7 and 8, running upwards, these being always calculated from the white side of the board (see diagram 1). Thus the White Queen's Rook's square is g8, the White Queen's square is d1; the Black Queen's square, d8; the White King's square, e1; the Black King's square, e8, and so with the other pieces and squares. The German names of the pieces are as follows:—King, König; Queen, Dame; Rook, Turm; Bishop, Läufer; Knight, Springer; Pawn, Bauer; Chess, Schach.
The initials only of the pieces are given, the pawns (Bauern) being understood. The Germans use the following signs in their notation, viz.:—for "check" (!); "checkmate" (!!); "takes" (!); "castles on king's side" (0-0); "castles on queen's side" (0-00); for "best move" a note of admiration (!); for "weak move" a note of interrogation (?). The opening moves just given in the English will now be given in the German notation:—

White. Black.
1. e2-e4 1. e2-e4
2. Sg1-f3 2. Sb1-c3
3. Lf1-c4 3. Lf1-e2
4. c2-e3 4. Sg8-f6
5. d2-d4 5. e5-d4:
6. c5-c4: 6. Lc5-b4:

In both notations the moves are often given in a tabular form, thus:

1. P-K4 1. P-K4
2. Kt-B3 2. QKt-B3
4. P-B3 4. Kt-KB3
5. P-Q4 5. P-KB3
6. P-K4 6. Q-K2
7. P-K5 7. R-K1
8. QKt-XB 8. RXB
10. Q-KT3 10. QKt-K2
11. Castles (K's side) 11. Castles

Even game.

RUY LOPEZ. Black.

White. 1. P-K4 1. P-K4
2. Kt-B3 2. QKt-B3
4. B-K3 4. Q-K2
5. P-Q4 5. PXP
6. B-K5 6. Q-Kt
7. Castles 7. Kt-B4
9. BXKt 9. QXKt
10. KtX 10. Castles
11. Kt-QB3 11. P-KB3

Even game.

SCOTCH GAMBIT.

White. 1. P-K4 1. P-K4
2. Kt-B3 2. QKt-B3
3. Q-K3 3. P-Q3
4. B-B4 4. B-B4
5. B-B3 5. Kt-B3
6. PXP 6. QXP
8. P-Q3 8. Q-Kt
10. PXP 10. RXKt
11. Castles 11. Q-Kt

The position here arrived at is the same as in the Giuoco Piano opening above.

EVANS GAMBIT.

White. 1. P-K4 1. P-K4
2. Kt-B3 2. QKt-B3
4. P-Q4 4. QKt-t4
5. P-B3 5. P-B3
6. QXP 6. QXP
8. P-Q3 8. Q-Kt
10. PXP 10. RXKt
11. Castles 11. Q-Kt

White has for its ninth move three approved continuations, viz. B-Kt2, P-Q5, and Kt-B3. To take one of them:

9. P-Q5 9. Kt-Q4
11. Castles 11. Castles
12. Kt-Kt3 12. Q-Kt
14. Q-Q2 14. P-B3
16. QR-B sq 16. R-Kt sq

This game may be considered about even.

CHESS

KING'S KNIGHT'S GAMBIT (PROPER). Black.
1. P-K4 1. P-K4
2. P-KB4 2. PXP
3. KKKt-B3 3. P-Kt4
5. Castles 5. P-Q6
7. P-B3 7. Kt-K2

Black has the advantage.

ALGAMAIER-KIESERITZKI GAMBIT.
White. 1. P-K4 1. P-K4
2. P-KB4 2. PXP

Draw.

This brilliant game, played at the Munich tournament, 1900, would be unique had the combinations occurred spontaneously in the game. As a matter of fact, however, the whole variation had been elaborated by Maroczy and Halprin previously, on the chance of Pillsbury adopting the defence in the text. The real merit belongs to Pillsbury, who had to find the correct defence to an attack which Halprin had committed to memory and simply had to be careful to move the pieces in regular order.

This game, played in the London tournament, 1883, is one of the most remarkable productions of modern times, neither surpassed nor indeed equalled hitherto.

End Games.—A game of chess consists of three branches—the opening, the middle and the end game. The openings have been analysed and are to be acquired by the study of the books on the subject. The middle game can only be acquired practically. The combinations being inexhaustible in their variety, individual ingenuity has its full scope. Those endowed with a fertile imagination will evolve plans and combinations leading to favourable issues. The less endowed player, however, is not left quite defenceless; he has necessarily to adopt a different system, namely, to try to find a weak point in the arrangement of his opponent's forces and concentrate his attack on that weak spot. As a matter of fact, in a contest between players of equal strength, finding the weak point in the opponent's armour is the only possible plan, and this may be said to be the fundamental principle of the modern school. In the good old days the battles were mostly fought in the neighbourhood of the king, each side striving for a checkmate. Nowadays the battle may be fought anywhere. It is quite immaterial where the advantage is gained be it ever so slight. Correct continuation will necessarily increase it, and the opponent may be compelled to surrender in the end game without being checkmated, or a position may be reached when the enemies, in consequence of the continual fight, are so reduced that the kings themselves have to take the field—the end game. The end game, therefore, requires a special study. It has its special laws and the value of the pieces undergoes a considerable change. The kings leave their passive rôle and become attacking forces. The pawns increase in value, whilst that of the pieces may diminish in certain cases. Two knights, for instance, without pawns, become valueless, as no checkmate can be effected with them. In the majority of cases the players must be guided by general principles, as the standard examples do not meet all cases.

The handbooks as a rule give a sprinkling of elementary endings, such as to checkmate with queen, rook, bishop and knight, two bishops, and pawn endings pure and simple, as well as pawns in connexion with pieces in various forms. Towards the end of the 19th century a valuable work on end games was published in England by the late B. Horwitz; thus for the first time a theoretical classification of the art was given. This was followed by a more comprehensive work by Professor J. Berger of Graz, which was translated a few years later by the late Mr Freeborough. A few specimens of the less accessible positions are given below:

Position from a Game played by the late J. G. Campbell in 1863.

Obviously White has to lose the game, not being able to prevent the pawns from queening. By a remarkably ingenious device White averts the loss of the game by stalemating himself as follows:

Position by Sarratt, 1868.

White wins as follows:

1. P-Kt6, RPXP 2. P-B6, P(BKt)×P 3. P-R6 and wins by queening the pawn. If...

Problems.—A chess problem has been described as “merely a position supposed to have occurred in a game of chess, being none other than the critical point where your antagonist announces checkmate in a given number of moves, no matter what defence you play,” but the above description conveys no idea of the

Position by B. Horwitz.

As a rule the game should be drawn. Supposing by a series of checks White were to compel Black to abandon the pawn, he would move K-R8; Q×P and Black is stalemate. Therefore the ingenious way to win is:
1. K-B4, P-B8=Q ch; K-Kt3 and wins. Or 1. . . . K-R8 (threatening P-B8=Kt); then 2. Q-Q2 preliminary to K-Kt3 now wins.

Position by B. Horwitz.

Without Black's pawn White could only draw. The pawn being on the board, White wins as follows:

Position by B. Horwitz.

White wins with two pieces against one—a rare occurrence.

Position by O. Schubert.

White wins as follows:

Position by B. Horwitz.

degree to which problem-composing has become a specialized study. Owing its inception, doubtless, to the practice of recording critical phases from actual play, the art of problem composition has so grown in favour as to earn the title of the “poetry” of the game.

Position by F. Amelung.

White with the inferior position saves the game as follows:
1. P—R6, F×P; 2. K—B3 dis. ch, K moves; 3. R—R2, or Kt2 ch, K×Kt; 4. K—Kt2 and draw, as Black has to give up the rook, and the RP cannot be queened, the Black bishop having no power on the White diagonal. Extremely subtle.

Position by B. Horwitz.

The main idea being to checkmate with the bishop, this is accomplished thus:

Position by A. Troitsky.

White wins as follows:

Position by B. Horwitz.

A position from actual play. White plays 1. R—B5 threatening to win a piece. Black replies with the powerful Kt—Kt5, threatening two mates, and finally White (Mr Hoffer) finds an ingenious sacrifice of the Queen—the saving clause. The following are the moves:
1. R—B5, Kt—Kt5; 2. Q—Kt8 ch, K—Kt3; 3. Q—K6 ch, K—R2; 4. Q—Kt8 ch, and drawn by perpetual check, as Black cannot capture the Queen with K or R without losing the game.

Position by Hoffer.

which would tend to “obscure the issue.” Hence the first object in a problem is to extract the maximum of finesse with a sparing use of the pieces, but “economy of force” must be combined with “purity of the mate.” A very common mistake, until comparatively recent years, was that of appraising the “economy” of a position according to the slenderness of the force used, but economy is not a question of absolute values. The true criterion is the ratio of the force employed to the skill demanded. The earliest composers strove to give their productions every appearance of real play, and indeed their compositions

The earliest known problem is ascribed to an Arabian caliph of the 9th century. The first known collection is in a manuscript (in the British Museum) of King Alphonso of Castile, dated 1250; it contains 103 problems. The collection of Nicolas of Lombardy, dated 1300, comprises 192 problems.
partook of the nature of ingenious end-games, in which it was usual to give Black a predominance of force, and to leave the White king in apparent jeopardy. From this predilection he was extricated by a series of checking moves, usually involving a number of brilliant sacrifices. The number of moves was rarely less than five. In the course of time the solutions were reduced to shorter limits and the beauty of quiet (non-checking) moves began to make itself felt. The early transition school, as it has been called, was the first to recognize the importance of economy, i.e. the representation of the main strategic point without any extraneous force. The mode of illustrating single-theme problems, often of depth and beauty, was being constantly improved, and the problems of C. Bayer, R. Willmers, S. Loyd, J. G. Campbell, F. Healey, "J. B." of Bridport, and W. Grimshaw are, of their kind, unsurpassed. In the year 1843 the "Indian" problem attracted much notice, and in 1861 appeared Healey's famous "Bristol" problem. To this period must be ascribed the discovery of most of those clever ideas which have been turned to such good account by the later school. In an article written in 1890 F. M. Teed mentions the fact that his incomplete collection of "Indians" totalled over three hundred.

In 1870 or thereabouts, the later transition period, a more general tendency was manifest to illustrate two or more finished ideas in a single problem with strict regard to purity and economy, the theory of the art received greater attention than before and the essays of C. Schwede, Kohtz and Kockelkorn, Lehner and Gelbfuss, helped to codify hitherto unwritten rules of taste. The last quarter of the 19th century, and its last decade especially, saw a marked advance in technique, until it became a common thing to find as much deep and quiet play embodied in a single first-class problem as in three or four of the old-time problems, and hence arose the practice of blending several distinct ideas in one elaborate whole.

In the composition of "two-movers" it is customary to allow greater elaticity and a less rigorous application of the principles of pure economy. By this means a greater superficial complexity is attained; but the Teutonic and Bohemian schools, and even English and American two-move specialists, recognize that complexity, if it involves the sacrifice of first principles, is liable to abuse. The blind master, A. F. Mackenzie of Jamaica, however, with a few others (notably T. Taverner, W. Gleave, H. and E. Bettman and P. F. Blake) have won some of their greatest successes with problems which, under stricter ruling, would not be allowed.

Bohemian (Czech) composers have long stood unrivalled as exponents of that blending of ideas which is the distinguishing trait of the later problem. Such is their skill in construction that it is rare to find in a problem of the Bohemian school fewer than three or four lines of play which, in economy and purity, are unimpeachable. Amongst [the earliest composers of this class Anton König, the founder of the school, Makovky, Drtna, Palcet and Pliacek deserve to be honourably mentioned, but it was not until the starting of a chess column in the weekly Journal Saddler that the merits of the new school were fully asserted. It was in 1871 that Jan Dobrusky contributed his first composition to that paper: he was followed by G. Chocholous, C. Kondelik, Pospisil, Dr Mazel, Kvicila, Kesl, Tuzar, Musil and J. Kotce; and later still, Havel, Traxler and Z. Mach were no unworthy followers of Dobrusky.

The faculty for blending variations is not without "the defects of its qualities," and consequently among the less able composers a certain tendency to repeat combinations of similar companion ideas is discernible at times, while the danger that facile construction might usurp the place of originality and strategy was already apparent to Chocholous when, in an article on the classification of chess problems (Deutsche Schachzeitung, 1860), he warned the younger practitioners of the Bohemian school against what has been dubbed by H. Von Gottschall Variablen-leiter, or "the grinding out of variations." When this one reservation is made few will be inclined to dispute the pre-eminence of the Bohemian school. To some tastes, however, a greater appeal is made by the deeper play of the older German school, the quaint fancy of the American composer Samuel Loyd, or the severity and freedom from "duals" which mark the English composers.

The idea of holding a problem competition open to the world was first mooted in connexion with the chess congress of 1851, but it was in 1854 that a tournament (confined to British composers) was first held. Since then a number of important problem tournaments have been held.

History of Chess.

The origin of chess is lost in obscurity. Its invention has been variously ascribed to the Greeks, Romans, Babylonians, Scythians, Egyptians, Jews, Persians, Chinese, Hindus, Arabsians, Aramaicans, Castilians, Irish and Welsh. Some have endeavored to fix upon particular individuals as the originators of the game; amongst others upon Japheth, Shen, King Solomon, the wife of Ravan, king of Ceylon, the philosopher Xerxes, the Greek chieftain Palamedes, Hermes, Aristotle, the brothers Lydo and Tyrhrone, Semiramis, Zenobia, Attalus (d. c. 200 B.C.), the mandarin Han-sing, the Brahman Sissa and Shatresucha, stated to be a celebrated Persian astronomer. Many of these ascriptions are fabulons, others rest upon little authority, and some of them proceed from easily traceable errors, as where the Roman games of Ludus Latrunculorum and Ludus Calculorum, the Welsh recreation of Tawlbwrdd (throw-board) and the ancient Irish pastime of Fithchealh are assumed to be identical with chess; so far as the Romans and Welsh are concerned, the contrary can be proved, while from what little is known of the Irish game it appears not to have been a sedentary game at all. The claims of the Chinese were advocated in a letter addressed by Mr Eyles Irwin in 1793 to the earl Charlemont. This paper was published in the Transactions of the Royal Irish Academy, and its purport was that chess, called in the Chinese tongue chong-ki (the "royal game") was invented in the reign of Kao-Tsu, otherwise Lin-Fang, then king, but afterwards emperor of Kiang-Nang, by a mandarin named Han-sing, who in command of an army, invading the Shen-Si country, and who wanted to amuse his soldiers when in winter quarters. This invasion of the Shen-Si country by Han-Sing took place about 174 B.C. Capt. Hiram Cox states that the game is called by the Chinese chueh-chao-hong ki, "the play of the science of war." (See also a paper published by the Hon. Daines Barrington in the 9th vol. of the Archaeologia.) Mr N. Bland, M.R.A.S., in his Persian Chess (London, 1850), endeavours to prove that the Persians were the inventors of chess, and maintains that the game, born in Persia, found a home in India, whence after a series of ages it was brought back to its birthplace. The view, however, which has obtained the most credence, is that which attributes the origin of chess to the Hindus. Dr Thomas Hyde of Oxford, writing in 1694 (De Ludis Orientalibus), seems to have been the first to propound this theory, but he appears to have been ignorant of the game itself, and the Sanskrit records were not accessible in his time. About 1783-1786 Sir William Jones, in an essay prefixed to the vol. I. of Asiatic Researches, argued that Hindustan was the cradle of chess. This statement has been known there from time immemorial by the name of caturanga, that is, the four gana, or members of an army, which are said in the Amarakosha to be elephants, horses, chariots and foot soldiers. As applicable to real armies, the term caturanga is frequently used by the epic poets of India. Sir William Jones's essay is substantially a translation of the Bhawisisky Purana, in which is given a description of a four-handed game of chess played with dice. A pandit named Radhakant informed him that this was mentioned in the oldest law books, and also that it was invented by the wife of Ravan, king of Lanka (Ceylon), in the second age of the world in order to amuse that monarch while Rama was besieging his metropolis. This account claims for chess an existence of 4000 or 5000 years. Sir William, however,grounds his opinions as to the Hindu origin of chess upon the testimony of the Persians and not upon the above manuscript, while he considers the game described therein to be more modern than the Persian game. Though sure that the latter came from India and was invented there, he admits that he could not find any account
of it in the classical writings of the Brahmins. He lays it down that chess, under the Sanskrit name chaturanga, was exported from India into Persia in the 6th century of our era; that by a natural corruption the old Persians changed the name into shatranj, but when their country was soon afterwards taken possession of by the Arabs, who had neither the initial nor final letter of the word in their alphabet, they altered it further into shatravan, which name found its way presently into modern Persian and ultimately into the dialects of India.

Capt. Hiram Cox, in a letter upon Burmese chess, written in 1799 and published in the 7th vol. of Asiatic Researches, refers to the four-handed game described in the Sanskrit manuscript to be the most ancient form of chess, the Burmese and Persian games being second and third in order of precedence. Later, in the 11th and 24th vols. of the Archæologia, Mr. Francis Douce and Sir Frederick Madden expressed themselves in favour of the views held by Hyde and his followers.

In Professor Duncan Forbes's History of Chess (1860) Capt. Cox's views, as founded upon Sir William Jones's Sanskrit manuscript, are upheld and are developed into an elaborate theory. Professor Forbes holds that the four-handed game described in the Sanskrit manuscript as chaturanga was the former form of chess; that it was invented by a people whose language was Sanskrit (the Hindus); and that it was known and practised in India from a time lost in the depths of a remote antiquity, and for a period the duration of which may have been from 3000 to 4000 years before the 6th century of the Christian era. He endeavours to show, but adduces no proof, how the four armies commanded by four kings in Sir William Jones's manuscript became converted into two opposing armies, and how two of the kings were reduced to a subordinate position, and became "monitors" or "counsellors," one standing by the side of the White and the other of the Black king, these counsellors being the "farins" from which we derive our "queens." Among other points he argues, apparently with justice, that chaturanga was evidently the root of shatranj, the latter word being a mere exotic in the language of the inhabitants of Persia.

Van der Linde, in his exhaustive work, Geschichte und Litteratur des Schachspiels (Berlin, 1874), has much to say of the origin-theories, nearly all of which he treats as so many myths. He agrees with those who consider that the Persians received the game of "chaturanga" from the Hindus; but the elaborate shatranj, that of Forbes receive but scant mercy. Van der Linde argues that chaturanga is always used by the old Indian poets of an army and never of a game, that all Sanskrit scholars are agreed that chess is not mentioned in really ancient Hindu records; that the Puranas generally, though formerly considered to be extremely old, are held in the light of modern research to reach no farther back than the 10th century—while the copies of the Bhavisjya Purana in the British Museum and the Berlin Library do not contain the extract relied upon by Forbes, though it is to be found in the Raghunandana, which was translated by Weber in 1872, and is stated by Bühler to date from the 16th century. The outcome of van der Linde's studies appears to be that chess certainly existed in Hindustan in the 8th century, and that probably that country is the land of its birth. He inclines to the idea that the game originated among the Buddhists, whose religion was prevalent in India from the yd to the 6th century. According to their ideas, war and the slaying of one's fellow-men, for any purposes whatever, is criminal, and the punishment of the warrior in the next world will be much worse than that of the simple murderer; hence chess was invented as a substitute for war. In opposition to Forbes, therefore, and in agreement with Sir William Jones, van der Linde takes the view that the four-handed game of the original manuscript is a comparatively modern adaptation of the Hindu chess, and he altogether denies that there is any proof that any form of the game has the antiquity attributed to it. Internal evidence certainly seems to contradict the theory that Sir William Jones's manuscript is very ancient testimony; for it mentions two great sages, Vyasa and Gotama, the former as teaching chaturanga to Prince Yudishthir, and the other as giving an opinion upon certain principles of the game; but this could not well be, seeing that it was played with dice, and that all games of hazard were positively forbidden by Manu. It would appear also that Indian manuscripts are not absolutely trustworthy as evidence of the antiquity of their contents; for the climate has the effect of destroying such writings in a period of 300 or 400 years. They must, therefore, be received from time to time and in this way later interpolations may easily creep in.

Van der Lasa, who, in an article prefixed to the Handbuch in 1864, accepted Forbes's views, withdrew his support in a review of the work just noticed, published in the September and November numbers of the Deutsche Schachzeitung, 1874, and expressed his adherence to the opinions of van der Linde.

Altogether, therefore, we find the best authorities agreeing that chess existed in India before it is known to have been played anywhere else. In this supposition they are strengthened by the names of the game and of some of the pieces. Shatranj, as Forbes has pointed out, is a foreign word among the Persians and Arabians, whereas its natural derivation from the termchaturanga is obvious. Again al-fil, the Arabic name of the bishop, means the elephant, otherwise alephhind, the Indian ox. Our earliest authority on chess is Masudi, an Arabic author who wrote about A.D. 950. According to him, shatranj had existed long before his time; and we think it may be stated not only for his own generation but for a couple of centuries before, that will give to chess an existence of over a thousand years.

Early and Mediaeval Times.—The dimness which shrouds the origin of chess naturally obscures also its early history. We have seen that chess crossed over from India into Persia, and became known in the latter country by the name of shatranj. Some have understood that word to mean "the play of the king"; but undoubtedly Sir William Jones's derivation carries with it the most plausibility. How and when the game was introduced into Persia we have no means of knowing. The Persian poet Firdusi, in his historical poem, the Shahnama, gives an account of the introduction of shatranj into Persia in the reign of Chosroes I. Anushirwan, to whom came ambassadors from the sovereign of Hind (India), with a chess-board and men asking him to solve the secrets of the game, if he could, or pay tribute. Chosroes I. was the contemporary of Justinian, and reigned in the 6th century A.D. Professor Forbes seems to think that this poem may be looked upon as an authentic history. This appears, however, to be somewhat dangerous, especially as Firdusi, 450 years after the supposed event took place; but since other Persians and Arabian writers state that shatranj came into Persia from India, there appears to be a consensus of opinion that may be considered to settle the question. Thus we have the game passing from the Hindus to the Persians and thence to the Arabs, after the capture of Persia by the Caliphs in the 7th century, and from them, directly or indirectly, to various parts of Europe, at a time which cannot be definitely fixed, but either in or before the 11th century. That the source of the European game is Arabic is clear enough, not merely from the words "check" and "mate," which are evidently from Shah mat ("the king is dead"), but also from the names of some of the pieces. There are various chess legends having reference to the 7th and 8th centuries, but these may be neglected as historically useless; and equally useless appear the many oriental and occidental romances which revolve around those two great central figures, Harun al-Rashid and Charlemagne. There is no proof that either of them knew anything of chess or, so far as the latter is concerned, that it had not been introduced into his time. True, there is an account given in Gustavus Selenus, which is based upon some precious old chronicles, as to the son of Prince Oktar or Otkar of Bavaria having been killed by a blow on the temple, struck by a son of Pippin after a game of chess; and there is another well-known tradition as to the magnificent chess-board and set of men said to have been sent over as a present by the empress Irene to Charlemagne. But both tales are not less mythical than the romance which relates how the great Frankish monarch lost his kingdom over a game of chess to Guérin de Montglaive; for van der Linde shows that there was no Bavarian prince of the name of Oktar or Otkar at the period alluded to, and as ruthlessly shatters the
tradition about Irene's chessmen. With respect to Harun al-Rashid, among the various stories told which connect him with chess, there is one that at first sight may seem entitled to some degree of credit. In the annals of the Moslems by Abulfeda (Abu'l Fida), there is given a copy of a letter stated to be "From Nicephorus, emperor of the Romans, to Harun, sovereign of the Arabs," which (using Professor Forbes's translation) after the usual compliments runs thus:--"The empress (Irene) into whose place I have succeeded, looked upon you as a Rukh and herself as a mere Pawn; therefore she submitted to pay you a tribute more than the double of which she ought to have exacted from you. All this has been owing to female weakness and timidity. Now, however, I insist that you, immediately on reading this letter, repay to me all the sums of money you ever received from her. If you hesitate, the sword shall settle our accounts." Harun's reply, written on the back of the Byzantine emperor's letter, was terse and to the point. "In the name of God the merciful and gracious. From Harun, the commander of the faithful, to the Roman dog Nicephorus. I have read thine epistle, thou son of an infidel mother; my answer to it thou shalt see, not hear. Harun was as good as his word, for he marched immediately as far as Heraclea, devastating the Roman territory as far as Nicomedia and beyond, and thus the Byzantine army prepared to sue for peace. Now the points which give authority to this narrative and the alleged correspondence are that the relations which they assume between Irene and Nicephorus on the one hand and the warlike caliph on the other are confirmed by the history of those times, while, also, the straightforward brevity of Harun's reply comments itself as what one might expect from his soldier-like character. Still, the fact must be remembered that Abulfeda lived about five centuries after the time to which he refers. Perhaps we may assume that it is not improbable that the correspondence is genuine; but that the words rukh and pawn may have been substituted for other terms of comparison originally used.

As to how chess was introduced into western and central Europe nothing is really known. The Spaniards very likely received it from their Moslem conquerors, the Italians not improbably from the Byzantines, and in either case it would pass northwards to France, going thence to Scandinavia and England. Some say that chess was introduced into Europe at the time of the Crusades, others that it did not come to Europe until the twelfth century, and some that the Crusaders themselves learned to play it at Constantinople. This is negatived by a curious epistle of St Peter Damian, cardinal bishop of Ostia, to Pope Alexander II., written about A.D. 1061, which, assuming its authenticity, shows that chess was known in Italy before the date of the first crusade. The cardinals, as it seems, had imposed a penance upon a bishop whom he had found diverting himself at chess; and in his letter to the pope he repeats the language he had held to the erring prelate, viz. "Was it right, I say, and consistent with thy duty, to sport away thy evenings amidst the vanity of chess, and defile the hand which offers up the body of the Lord, and the tongue that mediates between God and man, with the pollution of a sacrilegious game?" Following up the same idea that statutes of the church of Elna, in the 3rd vol. of the Councils of Spain, say, "Clerks playing at dice or chess shall be ipso facto excommunicated." Eudes de Sully, bishop of Paris under Philip Augustus, is stated in the Ordonn. des Rois de France to have forbidden clerks to play the game, and according to the Hist. Eccles. of Fleury, St Louis, king of France, imposed a fine on all who should play it. Ecclesiastical authorities, however, seemed to have differed among themselves upon the question whether chess was or was not a lawful game according to the canons, and Peirino (De Prodel. chap. 1) holds that it was permissible for ecclesiastics to play thereat. Among those who have taken an unfavourable view of the game may be mentioned John Huss, who, when in prison, deplored his having played at chess, whereby he had lost time and run the risk of being subject to violent passions. Among authentic records of the game may be quoted the Alexiad of the princess Anna Comnena, in which she relates how her father, the emperor Alexius, used to divert his mind from the cares of state by playing at chess with his relatives. This emperor died in 1118.

Concerning chess in England there is the usual confusion between legend and truth. Snorre Sturleson relates that as Canute was playing at chess with Earl Ulf, a quarrel arose, which resulted in the upsetting of the board by the latter, with the further consequence of his being murdered in church a few days afterwards by Canute's orders. Carlyle, in The Early Kings of Norway, repeats this tale, but van der Linde treats it as a myth. The Ramsey Chronicle relates how bishop Utheric, coming to Canute at night upon urgent business, found the monarch and his courtiers amusing themselves at dice and chess. There is nothing intrinsically improbable in this last narrative; but Canute died about 1035, and the date, therefore, is suspiciously early. Moreover, allowance must be made for the ease with which chroniclers described other games as chess. William the Conqueror, Henry I., John and Edward I. are variously stated to have played at chess. It is generally supposed that the English court of exchequer took its name from the cloth, figured with squares like a chess-board, which covered the table (see EXCHEQUER). An old writer says that at the coronation of Richard I. in 1189, six earls and barons carried a chess-board and the royal insignia to represent the exchequer court. According to Edmonson's Heraldry, twenty-six English families bore chess rooks in their coats of arms.

As regards the individual pieces, the king seems to have had the same move as at present; but it is said he could formerly be captured. His "casting" privilege is a European invention; but he formerly leaped two and even three squares, and also to his Kt 2nd. Casting dates no farther back than the first half of the 16th century. The queen has suffered curious changes in name, sex and power. In shatranj the piece was called fars or fers (also farzan, farzin and farzi), signifying a "counsellor," "minister" or "general." This was latinized into farzis or fercia. The French slightly altered the latter form into fierce, fierce, and as some say, vierge, which, if true, might explain its becoming a female. Another and much more probable account has it that whereas formerly a pawn on reaching an eighth square became a farzin, and not any other piece, which promotion was of the same kind as at draughts (in French, dames), so she became a Dame or queen as in the latter game, and thence dama, donna, damma, etc. In the old Latin mass in which the terms farzin, regina and dama are used indifferently. The queen formerly moved only one square diagonally and was consequently the weakest piece on the board. The immense power she now possesses seems to have been conferred upon her so late as about the middle of the 15th century. It will be noticed that under the old system the queens could never meet each other, for they operated on diagonals of different colours. The bishop's scope of action was also very limited formerly; he could only move two squares diagonally, and had no power over the intermediate square, which he could leap over whether it was occupied or not. This limitation of their powers prevailed in Europe until the 15th century. This piece, according to Forbes, was called among the Persians alf, an elephant, but the Arabs, not having the letter f in their alphabet, wrote it fl, or with their definite article al-fl, whence alphius, alfers, alfare, the latter being the word used by the Italians; while the French perhaps get their fol and fou from the same source. The pawns formerly could move only one square at starting; their powers in this respect were increased about the early part of the 16th century. It was customary for them on arriving at an eighth square to be exchanged only for a farzin (queen), and not any other piece; the rooks (so called from the Indian rukh and Persian rok, meaning a "soldier") and the knights appear to have always had the same powers as at present. As to the chessboards, they were formerly uncoloured, and it is not until the 17th century that we hear of checkered boards being used in Europe.

Development in Play.—The change of shatranj into modern chess took place most probably first in France, and thence made its way into Spain early in the 15th century, where the new game was called Axedrez de la dama, being also adopted by the Italians
under the name of *scacci alla rabiosa*. The time of the first important writer on modern chess, the Spaniard Ruy Lopez de Segura (1561), is also the period when the latest improvement, castling, was introduced, for his book (*Libro de la invencion liberal y arte del juego del Aedrez*), though treating of it as already in use, also gives the old mode of play, which allowed the king a leap of two or three squares. Shortly afterwards the old *shatranj* disappears altogether. Lopez was the first who merits the name of chess analyst. At this time flourished the flower of the Spanish and Italian schools of chess—the former represented by Lopez, Ceron, Santa Maria, Busnardo and Avalos; the latter by Giovanni Leonardo da Cutri (il Puttino) and Paolo Boi (il Sicurascano). In the years 1562-1575 both Italian masters visited Spain and defeated their Spanish antagonists. During the whole 17th century we find but one worthy to be mentioned, Giacchino Greco (il Calabrese). The middle of the 18th century inaugurates a new era in chess. The leading man of this time was François André Danican Philidor. He was born in 1726 and was trained by M. de Kermur, Sire de Légal, the star of the *Café de la Régence* in Paris, which has been the centre of French chess ever since the commencement of the 18th century. In 1749 he visited England, and defeated the Austrian player, Philipp Stamma, by 8 games to 1 and 1 draw. In 1749 he published his *Analyse des échecs*, a book which went through many editions and was more translated than any other work upon the game. During more than half a century Philidor travelled much, but never went to Italy, the only country where he could have found opponents of first-rate skill. Philidor was represented in Philidor's time by Ercole del Rio, Lolli and Ponziani. Their style was less sound than that of Philidor, but certainly much finer and in principle a better one. As an analyst the Frenchman was in many points refuted by Ercole del Rio ("the anonymous Moderner"). Blindfold chess-play, already exhibited in the 11th century by Arabian and Persian experts, was taken up afresh by Philidor, who played on many occasions three games simultaneously without sight of board or men. These exhibitions were given in London, at the Chess Club in St James's Street, and Philidor died in that city in 1795. As eminent players of this period must be mentioned Count Ph. J. van Zuylen van Nyewater (1743-1826), and the German player, J. Allgaier (1762-1828), after whom a well-known brilliant variation of the King's Gambit is named. Philidor was succeeded by Alexandre Louis Honoré Lebreton Deschappelles (1780-1847), who was also a famous whist player. The only player who is known to have fought Deschappelles not unsuccessfully on even terms is John Cochrane. He also lost a match (1821) to W. Lewis, to whom he conceded the odds of "pawn and move," the Englishman winning one and drawing the two others. Deschappelles' greatest pupil, and the strongest player France ever possessed, was Louis Charles Mahé de la Bourdonnais, who was born in 1797 and died in 1840. His most memorable achievement was his contest with the English champion, Alexander Macdonnell, the French player winning in the proportion of three to two.

The English school of chess began about the beginning of the 19th century, and Sarratt was its first leader. He flourished from 1808 to 1821, and was followed by his great pupil, W. Lewis, who will be principally remembered for his writings. Literary career belongs to the period from 1818 to 1848 and he died in 1869. A. Macdonnell (1798-1835) has been already mentioned. To the same period belong also Captain Evans, the inventor of the celebrated "Evans Gambit" (?1828), who died at a very advanced age in 1873; Perigal, who participated in the correspondence matches against Edinburgh and Paris; George Walker, for thirty years chess editor of *Bell's Life in London*; and John Cochrane, who met every strong player from Deschappelles downwards. In the same period Germany possessed but one good player, J. Mendheim of Berlin. The fifth decade of the 19th century is marked by the fact that the leadership passed from the French school to the English. After the death of la Bourdonnais, Fournié de Saint-Amant became the leading player in France; he visited England in the early part of 1843, and successfully met the best English players, including Howard Staunton (q.e.), but the latter soon took his revenge, for in November and December 1843 a great match between Staunton and Saint-Amant took place in Paris, the English champion winning by 11 games to 6 with 4 draws. During the succeeding eight years Staunton maintained his reputation by defeating Popert, Horwitz and Harrwitzz. Staunton was defeated by Anderssen at the London tournament in 1851, and this concluded his match-playing career. Among the contemporaries of Staunton may be mentioned Henry Thomas Buckle, author of the *History of Civilization*, who defeated Kieseritzki, Anderssen and Löwenthal.

In the ten years 1850-1840 a new school arose in Berlin, the seven leaders of which have been called "The Pleiades." These were Bledow (1795-1846), Bilguer (1815-1840), Hanstein (1810-1850), Mayet (1810-1868), Schorn (1820-1850), B. Horwitz (b. 1809) and von Heydebrand und der Lasa, once German ambassador at Copenhagen. As belonging to the same period must be mentioned the three Hungarian players, Grimm, Szen and J. Löwenthal.

The greatest masters since the middle of the 19th century Paul Morphy (1837-1884), an American, has seldom been surpassed as a chess player. His career was short but brilliant. Born in New Orleans in 1837, he was taught chess by his father when only ten years of age, and in two years' time became a strong player. When not quite thirteen he played three games with Löwenthal, and won two of them, the other being drawn. He was twenty years of age when he competed in the New York congress of 1857, where he won the first prize. In 1858 he visited England, and there defeated Boden, Medley, Mongréden, Owen, Bird and others. He also beat Löwenthal by 9 games to 3 and 2 drawn. In the same year he played a match at Paris with Harrwitzz, winning by 5 to 2 and 1 drawn; and later on he obtained a victory over Anderssen. On two or three occasions he played blindfold against eight strong players simultaneously, each time with great success. He returned to America in 1859 and continued to play, but with decreasing interest in the game, until 1866. He died in 1884.

Wilhelm Steinitz (b. 1836) took the sixth prize at the London congress of 1862. He defeated Blackburne in a match by 7 to 1 and 2 drawn. In 1866 he beat Anderssen in a match by 8 games to 6. In 1868 he carried off the first prize in the British Chess Association handicap, and in 1872 in the London grand tourney, also defeating Zukertort in a match by 7 games to 1 and 4 drawn. In 1873 he carried off the first prize at the Vienna congress; and in 1876 he defeated Blackburne, winning 7 games right off. In 1872-1874, in conjunction with W. N. Potter, he conducted and won a telegraphic correspondence match for London against Vienna. In Philidor's age it was considered almost incredible that he should be able to play three simultaneous games without seeing board or men, but Paulsen, Blackburne and Zukertort often played 10 or 12 such games, while as many as 14 and 15 have been so played.

In 1876 England was in the van of the world's chess army. English-born players then were Boden, Burn, Macdonnell, Bird, Blackburne and Potter; whilst among naturalized English players were Löwenthal, Steinitz, Zukertort, who died in 1888, and Horwitz. This illustrious contingent was reinforced in 1878 by Mason, an Irish-American, who came over for the Paris tournament; by Gunsberg, a Hungarian; and later by Teichmann, who also made England his home. English chess flourished under the leadership of these masters, the chief prizes in tournaments being consistently carried off by the English representatives. To gauge the progress made by the game since about 1875 it will suffice to give the following statistics. In London Simpson's Divan was formerly the chief resort of chess players; the St George's Chess Club was the principal chess club in the West End, and the City of London Chess Club in the east. About a hundred or more clubs are now scattered all over the city. Formerly only the British Chess Association existed; after its dissolution the now defunct Counties' Chess Association took
its place, and this was superseded by the re-establishment by Mr Hoffer of the British Chess Association, which again fell into abeyance after having organized three international tournaments—London, 1857; Bradford, 1888; and Manchester, 1890—and four national tournaments. There were various reasons why the British Chess Association ceased to exercise its functions, one being that minor associations did not feel inclined to merge their identity in a central association. The London League was established, besides the Northern Chess Union, the Southern Counties' Chess Union, the Midland Counties' Union, the Kent County Association; and there are associations in Surrey, Sussex, Essex, Hampshire, Wiltshire, Gloucestershire, Somersetshire, Cambridgeshire, Herefordshire, Leicestershire, Northamptonshire, Staffordshire, Worcestershire and Lancashire. All these associations are supported by the affiliated chess clubs of the respective counties. Scotland (which has its own association), Wales and Ireland have also numerous clubs.

Still, England did not produce one new eminent player between 1875 and 1905. First-class chess remained in the hands of the veterans Burn, Blackburne, Mason and Bird. The old amateurs passed away, their place being taken by a new generation of powerful amateurs, so well equipped that Great Britain could hold its own in an amateur contest among the national teams of Germany, Holland and Russia. The terms master and amateur are not used in any invidious sense, but simply as designating, in the former case, first-class players, and in the latter, those just on the borderland of highest excellence. The professional element as it existed in the heyday of Simpson's Divan almost disappeared, the reason being the increased number of chess clubs, where enthusiasts and students might indulge in their favourite pastime to their heart's content, tournaments with attractive prizes being arranged during the season. The former occupation of the masters vanished in consequence; the few who remained depended upon the passing visitors from the provinces who were eager to test their strength by the standard of the master. Blackburne visited the provinces annually, keeping the interest in first-class chess alive by his simultaneous play and his extraordinary skill as a blindfold player—unsurpassed until the advent of Harry Nelson Pillsbury (1872-1906), the leading American master since Morphy.

Germany has produced great chess players in Tarrasch, E. Lasker, Lipke, Fritz, Bardeleben, Walbrodt and Mason, besides the old masters. Oder Austria, produced Max Weiss, Schlechter, Marco and Hruby, to say nothing of such fine players as the Fleischs, Dr Mertner, Dr Kaufmann, Fahndrich, Jacques Schwarz and others. Hungary was worthily represented by Maroczy, Makovetz and Brody, Maroczy being the best after Charousek's death. Russia, having lost Janischt, Petroff and Schumoff, discovered Tchigorin, Janowsky, Schlessinger, Alpin, Winap and Taubenhaus. France showed a decline for many years, having only the veteran M. Arnaud de Rivière and the naturalized M. Rosenthal left, followed by Goetz and two good amateurs, MM. Didier and Billerard. Italy had only Signor Salvati, although Signor Reggio came to the fore. Holland had a fair number of players equal to the English amateurs, but no master since the promising young van Lennen died.

The first modern International Chess Tournament held in London in 1851 was the forerunner of various similar contests, each of which is a complete table:

**Tournaments:**

1868. English Championship Cup. 1 Blackburne, 2 De Vere, 3 Pillsbury.
1868. British Chess Association Handicap. 1 Steinitz, 2 Wisker, 3 Blackburne.
1868. Baden-Baden. 1 Andersen, 2 Steinitz, 3 Blackburne and Neumann.
1869. English Chess Cup. 1 Wisker, 2 Burn.
1870-1871. City of London Handicap. 1 Potter, 2 De Vere.
1871-1872. City of London Handicap. 1 Steinitz, 2 Reals.
1872. 2 London, 1 Blackburne, 2 Zukertort, 3 Pillsbury.
1871. English Chess Association Cup. 1 Wisker (becoming permanent holder of the cup), 2 De Vere.
1873. Vienna. 1 Steinitz, 2 Blackburne, 3 Andersen.
1873. Berlin. 1 Blackburne, 2 Zukertort, 3 Pillsbury.
1875. Paris. 1 Zukertort, 2 Winap (after a tie with Zukertort), 3 Blackburne.
1880. Wiesbaden. 1, 2, and 3, a tie between Blackburne, English and Schlechter.
1885. Berlin. 1 Blackburne, 2 Zukertort, 3 Tchigorin and Winap.
1885. Nuremberg. 1 Winap, 2 Zukertort, 3 Mason.
1885. London. 1 Zukertort, 2 Steinitz, 3 Blackburne.
1888. London. 1 Winap, 2 Blackburne, 3 Mason.
1888. London. 1 Blackburne, 2 and 3 Bird and Schallopp.
1888. London. 1 Blackburne, 2 Burn, 3 Gunsberg and Taubenhaus.
1888. London. 1 Blackburne, 2 Burn, 3 Schallopp, 4 Mason and Zukertort.
1888. Naples. 1 Gunsberg, 2 Mackenzie, 3 Mason and Bardeleben.
1889. New York. 1 Tchigorin and Weiss, 3 Gunsberg.
1889. Brussels. 1 Tschigorin, 2 Burn, 3 Rubinstein.
1891. Amsterdam. 1 Burn, 2 Lasker, 3 Mason. There were only nine competitors, Lasker unexpectedly losing to van Vliet by a trap.
1895. Manchester. 1 Tarrasch, 2 Blackburne, 3 Bird and Mackenzie.
1897. Dresden. 1 Tarrasch, 2 Makovetz and Porges. Blackburne received a special prize.
1894. Leipzig. 1 Tarrasch, 2 Lipke and Telchmann.
1895. Hastings. 1 Pillsbury, 2 Tchigorin, 3 Lasker. This tournament is historical for the first appearance of Pillsbury, the American champion, and Maroczy, the Hungarian champion.
1896. Nuremberg. 1 Lasker, 2 Maroczy, 3 Pillsbury and Tarrasch.
1896. Budapest. 1 Tchigorin, 2 Charousek, 3 Pillsbury.
1897. Berlin. 1 Blackburne, 2 and 3 Pillsbury, 4 Mason. English had to abandon the tournament and return to Vienna ill. He never recovered and died a few weeks later.
1898. Vienna. 1 Tarrasch, 2 Pillsbury, 3 Janowsky. Tarrasch achieved a maximum result in this tournament. Pillsbury's chances were better than his, but he managed to run him neck and neck and beat him in the tie match which followed.
1898. Prague. 1 Tarrasch, 2 Charousek, 3 Cohn and Tchigorin.
1899. London. 1 Lasker, 2 Janowsky, 3 Maroczy and Pillsbury. Janowsky sacrificed the second prize by trying to win a game against Steinitz when with an easy draw in hand he could have secured the second place for himself alone.
1900. Munich. Tie between Maroczy, Pillsbury and Steinitz for three chief prizes.
1901. Monte Carlo. 1 Janowsky, 2 Schlechter, 3 Tchigorin and Pillsbury. A novel rule was introduced at this tournament, viz. the first drawn game to count to each player, to be replayed, and in case of a draw again to count to each, and in case of win to the winner. Theoretically this seems logical, but in practice it was only a trap.
1902. Monte Carlo. 1 Pillsbury and Maroczy, 3 Janowsky.
1902. Hanover. 1 Janowsky, 2 Pillsbury, 3 Atkins.
1903. Monte Carlo. 1 Tarrasch, 2 Maroczy, 3 Pillsbury.
1905. Ostend. 1 Maroczy, 2 Tarrasch and Janowsky.
1908. Stockholm. 1 Steinitz and 2 Lasker, 3 Schlechter and 3 Rubinstein.
1906. Ostend. 1 Schlechter, 2 Maroczy, 3 Rubinstein.
1904. Nuremberg. 1 Marshall, 2 Duran, 3 Schlechter and Fleischmann.
1906. Vienna. 1 Mieses, 2 Duran, 3 Maroczy and Vidmar.
1907. Ostend. 1 Bernstein and Rubinstein, 2 Mieses.
1907. Ostend. 1 Tarrasch, 2 Schlechter, 3 Janowsky.
1907. Ostend. 1 Tarrasch, 2 Schlechter, 3 Janowsky.
1907. Ostend. 1 Black, 2 Rubinstein, 2 Janowsky.
1907. Ostend. 1 Rubinstein, 2 Maroczy, 3 Niemzowitch and Leonhardt.

In the absence of any recognized authority to confer the title
of chess champion of the world, it has usually been appropriated by the most successful competitor in tournaments. On this ground Tarrasch claimed the title in 1907, although Lasker, who had twice beaten Steinitz, the previous champion, in championship matches, in addition to such masters as Bird, Blackburne, Mieses and Marshall, was well qualified to assume it. Accordingly in arranging the programme for the tournament at Ostend in 1907 it was agreed that the winner of this contest should receive the title of tournament champion, and should play a match with Lasker for the championship of the world.

Tarrasch having proved successful at Ostend, the match between him and Lasker was played at Munich in September 1908, and resulted in the victory of Lasker by 8 games to 3 and 5 draws.

Chess has developed various schools of play from time to time. The theory of the game, however, did not advance in proportion to the enormous strides in its popularity. Formerly the theory of play had been enriched by such enthusiasts as Dr. Max Lange, Louis Paulsen, Professor Andersen, Neumann, Dr. Subl, Falkbeer, Kieseritzki, Howard Staunton, Dr. Zukertort, W. N. Potter and Steinitz, foremost amongst them being Louis Paulsen. These openings were thoroughly overhauled, new variations discovered and tested in practical play over the board. These are now things of the past. The masters who find flaws in old variations and discover new ones bring them to light only in matches or tournaments, as new discoveries have now a market value and may gain prizes in matches or tournaments.

The old “romantic school” consequently became extinct, and the eliminating process resulted in the retention of a small répertoire only, sufficient for practical purposes in important contests.

Gamble and kindred openings containing elements of chance were avoided, and the whole stock which a first-class player requires is a thorough knowledge of the “Ruy Lopez,” the “Queen’s Pawn Openings,” and the “French” and “Sicilian Defences”—openings which contain the least element of chance.

The rôles of being restricted it necessarily follows that the scope for grand combinations is diminished and only strategy or position play remains. The “romantic” school invariably aimed at an attack on the king’s position at any cost; nowadays the struggle is to obtain a minute advantage, and the whole plan consists in finding or creating a weak spot in the opponent’s arrangement of forces; such is the theory of the modern school, conceived and advocated by Steinitz. But it is a curious fact that Steinitz founded the modern school rather late in life. He felt his powers of combination waning, and being the world’s champion and eager to retain that title, he started the new theory. This novel departure revolutionized chess entirely. The attacking and combination style was sacrificed to a sound, sober and dry method; but Steinitz, strange to say, was not even the best exponent of his own theory, this position falling to younger players, Siegbert Tarrasch, Schlechter, Amos Burn and Emanuel Lasker. Pillsbury and Janovsky adhered to both styles, the former in a high degree, and so did Zukertort and Chigorin; Tchigorin being a free-lance with a style of his own.

The old charm of the game disappeared—in match and tournament play at least—and beauty was sacrificed to exact calculation and to scoring points. This is to be regretted, for the most beautiful games still occur when a player resorts to the gambits. One of the finest games in the Hastings tournament was played by Tchigorin against Pillsbury, and this was a “King’s Gambit Declined.” Chigorin won a “Bishop’s Gambit” against Dr. Lasker in the Nuremberg tournament; and some brilliant games occur in the “Queen’s Gambit Declined,” if either White or Black sacrifices the KP. Another reason why gambits should be adopted by players in tournaments is that competitors would necessarily be readily prepared for the regulation openings, so that the gambits might take them by surprise. After all, the new school is a natural consequence of the progress of the game.

Paulsen, Andersen and Tchigorin devoted a lifetime to the Evans Gambit, volumes of analyses were written on it, and then Lasker revives an obstacle defence, and the Evans Gambit disappears! Zukertort achieved a great success with "1. Kt to KB5" in the London tournament, 1883, and this, or the kindred "1. P to Q4," opening, has since become the trusty weapon in serious encounters. Lasker wrote Common Sense in Chess, and gave the best defences of the Ruy Lopez (a certain form of it); but the “common sense” was demolished in the Paris and Nuremberg tournaments, and old forms of that remarkable opening have to be refurbished. These instances will suffice to show the reason for the cautious style of modern times. The Molikes have replaced the Napoleonics.

The old versatility of style could be revived if club tournaments were organized differently. The players might be compelled to adopt one single opening only in a two-round contest, each player thus having attack and defence in turn. The next season another opening would form the programme, and so on. Even in international tournaments this condition might be imposed; the theory would be enriched; full scope would be given to power of combination and ingenuity; whilst the game would be more interesting.

There are still amateurs who devote their energies to the theory of the game; but so long as innovations or new discoveries are not tested by masters in serious games, they are of no value. Steinitz used to keep a number of new discoveries ready to be produced in masters’ contests, the result being that his novelties were regularly demolished when it came to a practical test. The mistake was that he did not try his novelties over the board with an opponent of equal strength, instead of trusting to his own judgment alone.

The British Chess Federation was instituted in 1904, its first congress being held at Hastings in that year, when a British championship, a ladies’ championship and a first-class amateur tournament were played. These competitions have been continued annually at the congresses of the federation, with the following results:

**British Championship.**

**Ladies’ Championship.**
1904. Hastings. 1 Mrs Atkins, 2 Mrs Anderson and Mrs Herrington.
1905. Southport. 1 Miss Finn, 2 Mrs Anderson and Mrs Houling.
1906. Shrewsbury. 1 Mrs Herrington, 2 Mrs Anderson, 3 Miss Ellis and Mrs Houling.
1907. Crystal Palace. 1 Mrs Herrington and Mrs Houling, 3 Mrs Anderson.

**First Class Amateur Tournament.**

In 1896 and following years matches between representative players of Great Britain and the United States respectively were played by cable, with the following results:

Since 1899 cable matches have also been played annually between representatives of English and American universities; of the first six three were won by England, the remaining three
being drawn. In English chess matches have been played annually since 1853 between the universities of Oxford and Cambridge, seven players on each side. Up to 1907 Oxford won eleven matches, Cambridge twenty-one, and three were drawn.

LITERATURE OF THE GAME.—The first known writer on chess was Jacobus de Cessolis (Jacopo Dacciosele), whose main object, however, though he gives the moves, &c., was to teach morals rather than chess. He was a Dominican friar, and his treatise, Solutum Ludi Scacchorum, scis et, Libellus de Moribus Hominum et Officis Nibilicis, was written before the year 1200. It was afterwards translated into French, and in the year 1474 Caxton, under the title of The Game and Playe of Chessse, printed an English translation of the French version. He had the Göttinger Handschrift, a work containing nine different openings and fifty problems. The author of this manuscript is not known. Then comes Vicent, a Spanish writer, whose book bears date 1495. Only the title-page has been preserved, the rest of the work having been lost in the first Chester war. Another Spanish author who wrote in or about 1497, we are better informed. His treatise, Repetición das Amores y Aria de Azedres, comprises various practical chess matters, including 150 positions, ill. (Leipzig, 1497); and various smaller treatises. The laws of these positions are identical with those in the Göttinger Handschrift.

In the 16th century works upon the game were written by Damiano, Ruy Lopez and Horatio Gianuilo della Mandita; in the 17th century by Castello, Letant, Piddor, Lasa and others. Of especial interest are the works of the authors of the Traité de la lance; in the 18th century by Benjamin Franklin, John Collins, Lewis, Silberschmidt, Gulamas Kassim and James Cochrane, George Walker, MacDonnell, Jaenisch, Petroff, von Bilguer, von der Lasa, Staunton, Kling and Horwitz, Bledow, Dubois, Kieseritzky, Max Lange, Lőwenthal, Dufraene, Neumann, Suhle, Zuckertort, Preti and others.

English chess owes much to W. Lewis and George Walker. But to Howard Staunton must be ascribed the most important share in creating the popular literature which the game achieved in England. Staunton's Chess Player's Handbook, (1843), was followed by the Chess Player's Companion (1847, and again revised in 1848). For want of further adequate revision many of its variations are now out of date; but taking the handbook as it was when issued, very high praise must be bestowed upon it. The Chess Players' Handbook (1850), Groves, Lewis and the authors of the Traité de la Lance; in the 18th century by Benjamin Franklin, John Collins, Lewis, Silberschmidt, Gulamas Kassim and James Cochrane, George Walker, MacDonnell, Jaenisch, Petroff, von Bilguer, von der Lasa, Staunton, Kling and Horwitz, Bledow, Dubois, Kieseritzky, Max Lange, Lőwenthal, Dufraene, Neumann, Suhle, Zuckertort, Preti and others.

The more important modern works the following may be mentioned: Vasquez, El ajedrez de memoria; La Odisea de Pablo Morphy (Havana, 1893); Bauer, Schachlexikon (Leipzig, 1893); Jean Dufraene, Kleines Lehrbuch des Schachspiels (6th ed., London, 1903); E. Freeborough and REV. C. E. Ranken, Chess Openings, Ancient and Modern; A. Longinos, Bailliage Buch (Berlin, 1893); Bachman, Gestriche Schackpartien (containing a number of brilliant games) (Amsbach, 1893-1899); E. H. Bird, Chess Problems and Reminiscences (London, 1860); Gilber, Two-Move Match (1844); Chess Novelties (1895); Max Lange, Paul Morphy (1894); C. Bardeleben and J. Mieses, Lehrbuch des Schachspiels (very useful); Jas. Mason, The Principles of Chess in Theory and Practice (1895); E. Freeborough, Dr. Tarrasch und seine Systeme (Leipzig, 1895); Dr. Eugen V. Schmidt, Systematische Anordnung von Schacherschreiuen (Veit & Co., Leipzig, 1895); Numa Preti, A B C des échecs (Paris, 1895); C. Salvadori, Teoria generale dei giuoco degli Scacchi (Genoa, 1895); W. T. Pierce and J. C. Andrews, Chess, 4th ed. (New York, 1895); L. Hoffer, Chess (Koutudige); E. Freeborough, Select Chess End-Games (London, 1895); Eudell, The Chess Finding King and Queen against King and Rook (London, 1895); Tassilo von Hohenfels, Principles of Chess (1897); H. W. Milner-Barry, Chess Practice and Theory, Geschichte und Literatur des Schachspiels (Leipzig, 1897); Dr. Lasker, Common Sense in Chess (London, 1896); Oscar Cordell, Neuester Leitfaden des Schachspiels (Berlin, 1896); and a vast number of other publications.

Further is the London Tournament Book (1883); Twelve Tournament Books of the German Chess Association (Veit & Co. pumps); London Tournament Book (1896); The Hastings Tournament Book (London, 1895); The Vienna Tournament Book, by Halprin and Marco (1900); The Newbergen Tournament Book, by Dr Tarrasch; The Book of the London Congress, by L. Hoffer (Longman, 1899); The Paris Tournament Book (Paris, 1900), by Rosenthal, &c.

The following are the best works in English on chess problems:—J. B. of Bridport, Chess Strategy (1868); F. Healey, A Collection of 200 Chess Problems (1866); English Chess Problems, edited by James Lane and W. T. Pierce (1876); H. J. Andrews, E. N. Frankers, and B. G. Laws, Chess Prizes, the Two-Move Match Book (1887); A. F. Mackenzie, Chess its Poetry and its Prece (Jamaica, 1887); J. A. Miles, Chess Stars (self-mates), (1888); James Rayner, Chess Problems (1890); B. G. Laws, The Two-Move Chess Problem Book (1891), The Two-Move Bouquet, compiled by F. G. Neeves (1897); Mr and Mrs. T. R. Botany (ed.), Chess Problems (2nd ed., 1898); E. B. Cook, T. Henery and C. A. Gilber, American Chess-Nuts (1888); Samuel Loyd, Chess Strategy (1878); W. H. Lyons, Chess-Nut Barks and how to open them (1886); C. A. Gilber, Cranks and Thieves of the Chess Board (1890); Complete Chess Problems, edited by C. F. Stubbis (1890); W. Pullitzer, Chess Harmonies (1894); G. E. Carpenter (N. Preti of Paris), 200 Chess Problems (1900).

CHEST

(Gr. κρυύον, Lat. cista, O. Eng. cist, chest, &c.), a large box of wood or metal with a hinged lid. The term is also used of a variety of kinds of receptacle; and in anatomy it is transcribed to the portion of the body covered by the ribs and breastbone (see Respiratory System). In the more ordinary meaning chests are, next to the chair and the bed, the most ancient articles of domestic furniture. The chest was the common receptacle for clothes and valuables, and was the direct ancestor of the "chest of drawers," which was formed by enlarging the chest and cutting up the front. It was also frequently used as a seat. Indeed, in its origin it took in great measure the place of the chair, which, although familiar enough to the ancients, had become a luxury in the days when the chest was already an almost universal possession. The chief use of chests was as wardrobes, but they were also often employed for the storing of valuables. In the early middle ages the rich possessed them in profusion, used them as portmanteaux, and carried them about from castle to castle. These portable receptacles were often covered with leather and embellished with heraldic designs. As houses gradually became less sparsely furnished, chests and wardrobes were often combined in one panel, and other movables were allowed to remain stationary, and the chest lost its covered top, and took the shape in which we best know it—that of an oblong box standing upon raised feet. As a rule it was made of oak, but it was sometimes of chestnut or other hard wood.

There are, properly speaking, three types of chest—the domestic, the ecclesiastical and the strong box or cofeer. Old domestic chests still exist in great number and some variety, but the proportion of those earlier than the latter part of the Tudor period is very small; most of them are Jacobean in date. Very frequently they were made to contain the store of household which a bride took to her husband upon her marriage. In the 17th century Bouille and his imitators glorified the marriage-cofer until it became a gorgeous casket, almost indeed a sarcophagus, inlaid with ivory and ebony and precious woods, and enriched with ormolu, supported upon a stand of equal magnificence. The Italian marriage-chests (cassone) were also of a richness which was never attempted in England. The main features of these chests (which are not infrequently are carved with names and dates) are a front with four or five doors, the feet being formed from prolongations of the "stiles" or the posts. There were, however, exceptions, and a certain number of 17th-century chests have separate feet, either circular or shaped after the indications of a somewhat later style. There is usually a strong architectural feeling about the chest, the front being divided into panels, which are plain in the more ordinary examples, and richly carved in the choicer ones. The plinth and frieze are often of well-defined guilloche work, or are carved with arabesques or conventionalized flowers. Architectural detail, especially the detail of wainscoting, has indeed been followed with considerable fidelity, many of the earlier chests being carved in the linenfold pattern, while the Jacobean examples are often mere reproductions of the pilastered and recessed oaken nattapels of the period. Occasionally a chest is seen which is inlaid with coloured woods, or with
geometrical parquetry. Perhaps the most elaborate type of English parquetry chest is that named after the vanished Palace of Nonesuch. Such pieces are, however, rarely met with. The entire front of this type is covered with a representation of the palace in coloured woods. Another class of chest is incised, sometimes rather roughly, but often with considerable geometrical skill. The more ordinary variety has been of great value to the forger of antique furniture, who has used its carved panels for conversion into cupboards and other pieces, the history of which is not easily un revelled by the amateur who collects old oak without knowing much about it. Towards the end of the 17th century chests were often made of walnut, or even of exotic woods such as cedar and cypress, and were sometimes clamped with large and ornamental brass bands and hinges. The chests of the 18th century were much larger than those of the preceding period, and as often as not were furnished with two drawers at the bottom—an arrangement but rarely seen in those of the 17th century—when they were often fitted with a small internal box fixed across one end for ready access to small articles. The chest was not infrequently unpanelled and unornamented, and in the latter period of its history this became the ruling type. It will not have been forgotten that the Mistletoe Bough chest that the Bard in his each line of the pathetic ballad of "The Mistletoe Bough" concealed herself, to her undoing.

Ecclesiastical chests appear to have been used almost entirely as receptacles for vestments and church plate, and those which survive are still often employed for the preservation of parish documents. A considerable variety of these interesting and often exceedingly elaborate chests are still left in English churches. They are usually of considerable size, and of a length disproportionate to their depth. This no doubt was to facilitate the storage of vestments. Most of them are of great antiquity. Many go back to the 14th century, and here and there they are even earlier, as in the case of the coffin in Stoke d'Abernon church, Surrey, which is unquestionably 13th-century work. One of the most remarkable of these early examples is in Newport church, Essex. It is one of the extremely rare painted coffers of the 13th century, the front carved with an upper row of shields, from which the heraldic painting has disappeared, and a lower row of roundels. Between is a belt of open tracery, probably of pewter, and the inside of the lid is decorated with oil paintings representing the Virgin Mary, St Peter, St John, and St Paul. The well-known "jewel chest," in St Mary's, Oxford, is one of the earliest examples of 14th century work. Many of these ecclesiastical chests are carved with architectural motives—tracery windows most frequently, but occasionally with the linenfold pattern. There is a whole class of chests known as "tilting coffers," carved with representations of tournaments or feats of arms, and sometimes with a grotesque admixture of chivalric figures and mythical monsters. Only five or six examples of this type are known still to exist in England, and two of them are now in the Victoria and Albert Museum. It is not certain that even these few are of English origin—indeed, very many of the chests and coffers of the 16th and 17th centuries are of foreign make. They were imported into England chiefly from Flanders, and were subsequently carved by native artisans, as was the case with other common pieces of furniture of those periods. The huche or "hutch" was a rough type of household chest.

The word "coffer" is properly applied to a chest which was intended for the safe keeping of valuables. As a rule the coffers are much more massive in construction than the domestic chest; it is clamped by iron bands, sometimes contains secret receptacles opening with a concealed spring, and is often furnished with an elaborate and complex lock, which occupies the whole of the underside of the lid. Pieces of this type are sometimes described as Spanish chests, from the belief that they were taken from ships belonging to the Armada. It is impossible to say that this may not sometimes have been the case, but these strong boxes are frequently of English origin, although the mechanism of the locks may have been due to the subtle skill of foreign locksmiths. A typical example of the treasure chest is that which belonged to Sir Thomas Bodley, and is preserved in the Bodleian library at Oxford. The locks of this description of chest are of steel, and are sometimes richly damascened. It was for being implicated in the breaking open and robbing of just such a chest as this, to which the Collège de Navarre had confided coin to the value of 500 écus, that François Villon was hanged on the gibbet of Montfaucon.

**CHESTER, EARLS OF—CHESTER**

The important palatine earldom of Chester was first held by a certain Fleming named Gherbod (fl. 1070), and then by Hugh of Avranches (d. 1101), a son of Richard, viscount of Avranches. Hugh, who was probably one of William the Conqueror's companions, was made earl of Chester in 1071; he had special privileges in his earldom, and he held land in twenty counties. He was called Le Gros on account of his great bulk and Lupus on account of his ferocity. However, he regarded St Anselm as his friend, and he showed the customary liberality to religious houses. His life was mainly spent in fighting the Welsh and in Normandy, and he died on the 27th of July 1101. Hugh's only son Richard, who was childless, was drowned in the White Ship in November 1120. Among subsequent holders were Ralph, or Randulph, de Gernon (d. 1153), and his son, who was a prominent part in the civil wars of the reign of Stephen, fighting for Duke William of Eu against his son Hugh de Kevicelo (1147–1181), who shared in the rising against Henry II. in 1173. But perhaps the most celebrated of the early earls was Ralph, Ranulf, or Randulph, de Blundeville (c. 1172–1232), who succeeded his father Hugh de Kevicelo as earl in 1181, and was created earl of Lincoln in 1217. Ranulf married Constance, widow of Henry II.'s son, Geoffrey of Brittany, and is sometimes called duke of Brittany and earl of Richmond. He fought in Wales, was on the side of John during his struggle with the barons over Magna Carta, and was one of this king's executors; he also fought for the young king Henry III. against the French invaders and their allies. In 1218 he went on crusade to the Holy Land and took part in the capture of Damietta; then returning to England he died at Wallingford in October 1232. After speaking of Ranulf's unique position in the kingdom, which "fitted him for the part of a leader of opposition to royal or ministerial tyranny," Stubbs sums up his character in these words: "On more than one occasion he refused his consent to taxation which he deemed unjust; his jealousy of Hubert (de Burgh), although it was necessary, led the foreign party in 1223, did not prevent him from more than once intervening in the overthrow of his overlord. He was, moreover, almost the last relic of the great feudal aristocracy of the Conquest." Although twice married he left no children, and his immense possessions passed to his four sisters. The earl's memory remained green for a long time, and in the Vision of Piers Plowman his name is linked with that of Robin Hood. In November 1232 the earldom of Chester was granted to his nephew John the Scot, earl of Huntingdon (c. 1207–1237), and in 1246, nine years after John had died childless, it was annexed to the English crown "lest so fair a dominion should be divided among women."

In 1254 Prince Edward, afterwards King Edward I., was created earl of Chester, and since this date the earldom has always been held by the heirs apparent to the English crown with the single exception of Simon de Montfort, earl of Leicester. Since 1309 the earls of Chester have been also princes of Wales, although the act of Richard II. (1308), which created Chester into a principality to be held by the king's eldest son, was revoked by Henry IV.

**CHESTER,** an episcopal city and county of a city, municipal, county and parliamentary borough, and the county town of Cheshire, England, 179 m. N.W. of London. Pop. (1901) 38,309. It lies in a low plain on the Dee, principally on the north (right) bank, 6 m. above the embouchure of the river into its wide, shallow estuary. It is an important railway centre, the principal lines serving it being the London & North-Western, Great Western, Cheshire Lines and Great Central. The city is divided into four principal blocks by the four principal streets—Northgate Street, Eastgate Street, Bridge Street and Watergate Street, which radiate at right angles from the Cross, and terminate in
the four gates. These four streets exhibit in what are called "the Rows" a characteristic feature of the city. Their origin is a mystery, and has given rise to much controversy. In Eastgate Street, Bridge Street and Watergate Street, the Rows exist on each side of the street throughout the greater part of its length, and may be described as continuous galleries open to the street, over and under which the houses lining the streets project, and which are formed as it were out of the front floor of the houses, approached by flights of steps from the roadway. The Rows are flagged or boarded under foot and ceiled above, thus forming a covered way, standing in the same relation to the shops, which are at their back, as the foot pavements of the other towns. In Northgate Street, on the other hand, the Row on the west side is formed as it were out of the ground floor of the houses, having cellars beneath, while on the east side the Row is formed at the same elevation as in the other three principal streets. In these streets are several examples of old timbered houses and some good modern imitations of them,—all combining to give a picturesque and individual character to the city. Among the most interesting of the ancient houses are Derby House, bearing the date 1591, Bishop Lloyd's house, and God's Providence House in Watergate Street, and the Burton and Billet in Lower Bridge Street: the last date from the 17th century. There is also a chamber with stone groined roof of the 14th century in the basement of a house in Eastgate Street, and another of a similar character in Watergate Street. A mortuary chapel of the early part of the 13th century exists in the basement of a house in Bridge Street.

Chester is the only city in England that still possesses its walls perfect in their entire circuit of 2 m. The gateways have all been rebuilt at various dates; the north and east gates on the site of the Roman gates. The Grosvenor bridge, a single span of stone 200 ft. in length, said to be the largest save one in Europe, carries the road to Wrexham and Shrewsbury over the Dee on the south-west; while the old bridge of seven arches is interesting on account of its antiquity and picturesque ness. The castle, with the exception of "Caesar's Tower," and a round tower with adjacent buildings, in the upper ward, was taken down towards the end of the 18th century, and replaced by a gateway, barracks, county hall, gaol and assize courts.

The cathedral church of Christ and the Virgin Mary, which stands towards the north-east of the city within the walls, rose on the site of an ancient church of extreme antiquity. It appears that the dedication of this church was altered, perhaps in the reign of Athelstan, from St. Peter and St. Paul to St. Werburgh and St. Oswald, St. Werburgh being a niece of St. Etheldreda of Ely. In 1003 Hugh Lupus, earl of Chester, richly endowed the foundation as a Benedictine monastery. The bishops of Mercia had apparently a seat at Chester, but the city had ceased to be episcopal, until in 1075 Peter, bishop of Lichfield, removed his seat thence to Chester, having for his cathedral the collegiate church of St. John. The seat of the see, however, was quickly removed again to Coventry (1122), but Cheshire continued subject to Lichfield until in 1341 Chester was erected into a bishopric by Henry VIII., the church of the dissolved abbey of St. Werburgh becoming the cathedral. The diocese covers nearly the whole of Cheshire, with very small portions of Lancashire and Staffordshire. The cathedral does not rank among the most splendid English churches, but possesses certain details of the highest interest, and gains in beauty from the tones of its red sandstone walls and the picturesque effect in which it stands. Its cruciform with a central tower 127 ft. high. The south transept is larger than the north. The nave is short (145 ft.), being of six bays; the southern arcade is Decorated, while the northern, which differs in detail, is of uncertain date. The basement of the north-western tower—all that remains of it, now used as a baptistery—is Norman, and formed part of Hugh Lupus' church; and the fabric of the north wall is also of this period. The north transept also retains Norman work, and its size shows the original plan, as the existence of the conventual buildings to the north probably rendered its extension undesirable. The south transept has aisles, with Decorated and Perpendicular windows. The fine organ stands on a screen across the north transept; but some of its pipes are upon the choir screen, both screens being the work of Sir Gilbert Scott. The style of the choir is transitional from Early English to Decorated, and its length is 125 ft. It is a fine example, and its beauty is enhanced by the magnificent series of ancient carved wooden stalls unsurpassed in England. The Lady Chapel, east of the choir, is of rich Early English workmanship. Of the conventual buildings the cloisters are Perpendicular. The chapter-house, entered by a beautiful vestibule from the east cloister, and lined with cases containing the chapter library, is Early English (c. 1240). The refectory, adjoining the north cloister, is of the same period, with Perpendicular insertions; it has been curtailed in size, but retains its beautiful Early English lector's pulpit. An early Norman chamber, with massive pillars and vaulting, adjoins the west cloister, and may be the substructure of the abbot's house. The abbey gateway is of the 14th century.

Within the walls there are several churches of ancient foundation; thus St. Peter's is said to occupy the site of a church erected by Æthelflaed, queen of Mercia, and St. Mary's dates from the 12th century. None, however, is of any special interest; but St. John the Baptist, of which the wall, which as already stated became the cathedral in 1075, is a massive early Norman structure, with later additions, and, especially as regards the exterior, considerably restored in modern times. Its fine tower fell in 1881. It was a collegiate church until 1547, and there are some remains of the adjoining buildings. Among numerous modern churches there may be mentioned St. Mary's without the walls, built in 1887 by the duke of Westminster, of red sandstone, with a fine spire and peal of bells.

Among the chief secular buildings, the town hall replaced in 1869 the old exchange, which had been burnt down in 1862. The Grosvenor Museum and School of Art, the foundation of which was suggested by Charles Kingsley the novelist, when canon of Chester cathedral, contains many local antiquities, along with a fine collection of the fauna of Cheshire and the neighbourhood. The King's school was founded by Henry VIII. (1541), who provided that twenty-four poor scholars should be taught free of cost. It was reorganized as a public school in 1873, and possesses twelve king's scholarships tenable in the school, and college scholarships tenable at the universities. Among other schools may be mentioned the blue-coat school (1700), the Queen's school for girls (1878), the girls' school attached to the Roman Catholic convent, and the diocesan training college for schoolmasters. For recreation provision is made by the new Grosvenor Park, presented to the city in 1867 by the marquess of Westminster; Handbridge Park, opened in 1862; and the Roeode, a level tract by the river at the base of the city wall, appropriated as a race-course. An annual race-meeting is held in May and attended by thousands. The chief event is the race for the Chester Cup, which dates from 1540, when a silver bell was given as the prize by the Saddler's Company. Pleasure vessels ply on the Dee in summer, and an annual regatta is held, at which all the principal northern rowing-clubs are generally represented. The town gains in prosperity from its large number of visitors. The principal industries are carried on without the walls, where there are lead, shot and paint works, leather and tobacco factories, and iron foundries. The trade goods number twenty-four. There is a considerable amount of shipping on the Dee, the navigation having been much improved in modern times. The town council borough returns one member. The municipal council consists of a mayor, 10 aldermen and 30 councillors. Area, 2862 acres.

History.—Setting aside the numerous legends with regard to the existence of a British city on the site now occupied by Chester, the earliest authentic information relating to its history is furnished by the works of Ptolemy and Antoninus. As the Roman station of Deva it was probably founded about A.D. 48 by Ostius Scapula, and from its advantageous position, both as the key to communication with Ireland and as a bulwark against the hostile tribes of the north, it became a military and commercial centre of considerable importance. In A.D. 78-79
it was the winter-quarters of Agricola, and later became illustrious as the permanent headquarters of Legio XXVIII. Valeria Victrix. Many inscriptions and remains of the Roman military occupation have been found, and the north and east walls stand in great part on Roman foundations. The Saxon form of the name was Leganceaster. About 614 the city was captured and destroyed by Æthelfrith, and henceforth lay in ruins until Æthelstan in 907 rebuilt the walls, restored the monastery of St Werburgh, and made the city “nigh two such as it was before.” In the reign of Æthelstan a mint was set up at Chester, and in 973 it was the scene of Edward’s triumph when, it is said, he was rowed on the Dee by six subject kings. Chester opposed a determined resistance to the Conqueror, and did not finally surrender until 1070. On the erection of Cheshire to a county palatine after the Conquest, Chester became the seat of government of the palatine earls. The Domescadal account of the city includes a description of the Saxon laws under which it had been governed in the time of Edward the Confessor. All the land, except the bishop’s borough, was held of the earl, and assessed at fifty hides. There were seven mint-masters and twelve magistrates, and the city paid a fee-farm rent of £45. It had been much devastated during the time of Edward the Confessor, and the number of houses reduced by 205.

The earliest extant charter, granted by Henry II. in 1160, empowered the burgesses to trade with Durham as freely as they had done in the reign of Henry I. From this date a large collection of charters enumerates privileges granted by successive earls and later sovereigns. One from Ralph or Ranulf de Blundeville, granted between 1190 and 1211, confirms to the citizens a gild merchant and all liberties and free customs, and three from John protect their privilege of trading with Ireland. Edward I. empowered the citizens to elect coroners and to hold courts of justice, and granted them the fee-farm of the city at a yearly rent of £100. In the 14th century Chester began to lose its standing as a port through the gradual silting up of the estuary of the Dee, and the city was further impoverished by the inroads of the Welsh and by the necessity of rebuilding the Dee bridge, which had been swept away by an unusually high tide. In consideration of these misfortunes Richard II. remitted part of the fee-farm. Continued misfortunes led to a further reduction of the sum to £50 for a term of fifty years. Under Henry VII. it was also made a grant for the completion of a new Dee bridge. Henry VII. reduced the fee-farm to £20, and in 1506 granted to the citizens what is known as “the Great Charter.” This charter constituted the city a county by itself, and incorporated the governor body under the style of a mayor, twenty-four aldermen and forty common councilmen; it also instituted two sheriffs, two coroners and a recorder, and the mayor, the ex-mayors and the recorder were appointed justices of the peace. This charter was confirmed by James I. and Charles II. A charter of George III. in 1804 instituted the office of deputy-mayor. The charter of Hugh Lupus to the abbey of St Werburg includes a grant of the tolls of the fair at the feast of St Werbugh for three days, and a subsequent charter from Ranulf de Blundeville (12th century) licensed the abbot and monks to hold their fairs and markets before the abbey gates. A charter of John the Scot, earl of Chester, mentions fairs at the feasts of the Nativity of St John Baptist and St Michael. For many centuries the rights claimed by the abbot in connexion with the fairs have been exercised by the city, and the authorities, which lasted until, in the reign of Henry VIII., it was decreed that the right of holding fairs was vested exclusively in the citizens. Charles II. in 1685 granted a cattle-fair to be held on the 1st Thursday in February.

In 1553 Chester first returned two members to parliament, having hitherto been represented solely in the parliament of the palatinate. By the Redistribution Act of 1885 the representation was reduced to one member. The trades of tanners, skinners and glove-makers existed at the time of the Conquest, and the importation of marten skins is mentioned in Domesday. In the 14th century the woolen trade was considerable, and in 1674 weavers and wool-combers were introduced into Chester from Norwich. The restoration of the channel of the Dee opened up a flourishing trade in Irish linen, which in 1786 was at its height, but from that date gradually diminished.

See Victoria County History, Cheshire; R.H. Morris, Chester in the Plantagenet and Tudor Reigns (Chester, 1894); Joseph Heningway, History of the City of Chester (2 vols., Chester, 1831).

CHESTER, a city of Delaware county, Pennsylvania, U.S.A., on the Delaware river, about 13 m. S.W. of Philadelphia. Pop. (1890) 20,226; (1900) 33,988, of whom 5074 were foreign-born and 4403 were negroes; (U.S. census, 1910) 38,537. It is served by the Baltimore & Ohio and the Philadelphia & Reading railways, by the Philadelphia, Baltimore & Washington division of the Pennsylvania system, and by steamboat lines. Chester has several interesting buildings dating from early in the 18th century—among them the city hall (1774), one of the oldest public buildings in the United States, and the house (1683) occupied for a time by William Penn. It is the seat of the Pennsylvania Military College (1862); and on the border of Chester, in the borough of Upland (pop. in 1900, 2131), is the Crozer Theological Seminary (Baptist), which was incorporated in 1867, opened in 1868, and named after John P. Crozer (1793-1866), the master of the family it was founded. Chester has a large shipbuilding industry, and manufactories of cotton and worsted goods, iron and steel, the steel-casting industry being especially important, and large quantities of wrought iron and steel pipes being manufactured. Dye-stuffs and leather also are manufactured. The value of the city's factory products in 1905 was $16,644,842. Chester is the oldest town in Pennsylvania. It was settled by the Swedes about 1645, was called Upland and was the seat of the Swedish courts until 1682, when William Penn, soon after his landing at a spot in the town now marked by a memorial stone, gave it its present name. The first provincial assembly was convened here in December of the same year. After the battle of Brandywine in the War of Independence, Washington retreated to Chester, and in the "Washington House," still standing, wrote his account of the battle. Soon afterwards Chester was occupied by the British. In 1701 it was incorporated as a borough; in 1795 and again in 1850 it received a new borough charter; and in 1865 it was chartered as a city. For a long time it was chiefly a small fishing settlement, but from as late as 1820 being only 657; but after the introduction of large manufacturing interests in 1850, when its population was only 1667, its growth was rapid.

See H. G. Ashmead, Historical Sketch of Chester (Chester, 1883).

CHESTERFIELD, PHILIP DORMER STANHOPE, 4TH EARL OF (1694-1773), son of Philip Stanhope, third Earl (1673-1726), and Elizabeth Savile, daughter of George Savile, marquis of Halifax, was born in London on the 22nd of September 1694; Philip, the first earl (1654-1656), son of Sir John Stanhope of Shellow, was a royalist who in 1616 was created Baron Stanhope of Shellow, and in 1628 earl of Chesterfield; and his grandson the 2nd earl (1633-1714) was grandfather of the 4th earl. Deprived at an early age of his mother, the care of the boy devolved upon his grandfather, the marchioness of Halifax, a lady of culture and connexion, whose house was frequented by the most distinguished Whigs of the epoch. He soon began to prove himself possessed of that systematic spirit of conduct and effort which appeared so much in his life and character. His education, begun under a private tutor, was continued (1712) at Trinity Hall, Cambridge; here he remained little more than a year and seems to have read hard, and to have acquired a considerable knowledge of ancient and modern languages. The great orators of all times were a special object of study with him, and he describes his boyish pedantry pleasantly enough, but by no means without a touch of self-satisfaction in the memory. His university training was supplemented (1714) by a continental tour, unrammelled by a governor; at the Hague his ambition for the applause awarded to adventure made a gamester of him, and at Paris he began, from the same motive, that worship of the conventional Venus, the serious inculation of which has earned for him the largest and most unenviable part of his reputation.
The death of Anne and the accession of George I. opened up a career for him and brought him back to England. His relative James Stanhope (afterwards first Earl Stanhope), the king's favourite minister, procured for him the place of gentleman of the bedchamber to the prince of Wales. In 1715 he entered the House of Commons as Lord Stanhope of Shelgrove and member for St Germans, and when the impeachment of James, duke of Ormonde, came before the House, he used the occasion (5th of August 1715) to put to proof his old rhetorical studies. His maiden speech was youthful, fluent and dogmatic; but on its conclusion the orator was reminded with many compliments, by an honourable member, that he wanted six weeks of his majority, and consequently that he was amenable to a fine of £500 for speaking in the House. Lord Stanhope quitted the Commons with a low bow and started for the continent. From Paris he rendered the government important service by gathering and transmitting information respecting the Jacobite plot; and in 1716 he returned to England, resumed his seat, and took frequent part in the debates. In that year came the quarrel between the king and the heir apparent. Stanhope, whose political instinct obliged him to worship the rising sun, and natural fidelity to the prince, though he was too cautious to break entirely with the king's party. He was on friendly terms with the prince's mistress, Henrietta Howard, afterwards countess of Suffolk. He maintained a correspondence with this lady which won for him the hatred of the princess of Wales (afterwards Queen Caroline). In 1723 a vote for the government got him the place of captain of the Gentleman Pensioners. In January 1725, on the revival of the Bath, the red riband was offered to him, but was declined.

In 1726 his father died, and Lord Stanhope became earl of Chesterfield. He took his seat in the Upper House, and his oratory, never effective in the Commons by reason of its want of force and excess of finish, at once became a power. In 1728 Chesterfield was sent to the Hague as ambassador. In this place his tact and temper, his dexterity and discrimination, enabled him to do good service, and he was rewarded with Walpole's friendship, a Garter and the place of lord high steward. In 1732 there was born to him, by a certain Mile duc de Bouchet, the son, Philip Stanhope, for whose advice and instruction were afterwards given the famous letters to his brother George. In 1735 the treaty of Vienna, and in the next year, being somewhat broken in health and fortune, he resigned his embassy and returned to England.

A few months' rest enabled him to resume his seat in the Lords, of which he was one of the acknowledged leaders. He supported the ministry, but his allegiance was not the blind fealty Walpole exacted of his followers. The Exchequer Bill, the grand premier's favourite measure, was vehemently opposed by him in the Lords, and by his three brothers in the Commons. Walpole bent before the storm and abandoned the measure; but Chesterfield was summarily dismissed from his stewardship. For the next two years he led the opposition in the Upper House, leaving no stone unturned to effect Walpole's downfall. In 1741 he signed the protest for Walpole's dismissal and went abroad on account of his health. He visited Voltaire at Brussels and spent some time in Paris, where he associated with the younger Crébillon, Fontenelle and Montesquieu. In 1742 Walpole fell, and Carteret was his real, though not his nominal successor. Although Walpole's administration had been overthrown largely by Chesterfield's minuscule support, he did not contest Chesterfield either in its ranks or among its supporters. He remained in opposition, distinguishing himself by the courteous bitterness of his attacks on George II., who learned to hate him violently. In 1743 a new journal, Old England; or, the Constitutional Journal appeared. For this paper Chesterfield wrote under the name of "Jeffrey Broadbottom." A number of pamphlets, in some of which Chesterfield had the help of Edmund Waller, followed. His energetic campaign against George II. and his government won the gratitude of the dowager duchess of Marlborough, who left him £20,000 as a mark of her appreciation. In 1744 the king was compelled to abandon Carteret, and the coalition or "Broad Bottom" party, led by Chesterfield and Pitt, came into office. In the troublous state of European politics the earl's conduct and experience were more useful abroad than at home, and he was sent to the Hague as ambassador a second time. The object of his mission was to persuade the Dutch to join in the War of the Austrian Succession and to arrange the details of their assistance. The success of his mission was complete; and on his return a few weeks afterwards he received the lord-lieutenancy of Ireland—a place he had long coveted.

Short as it was, Chesterfield's Irish administration was of great service to his country, and is unquestionably that part of his political life which does him most honour. To have conceived and carried out a policy which, with certain reservations, Burke himself might have originated and owned, is indeed no small title to regard. The earl showed himself finely capable in practice as in theory, vigorous and tolerant, a man to be feared and a leader to be followed; he took the government entirely into his own hands, repressed the jockeyry traditional to the office, established schools and manufactures, and at once conciliated and kept in check the Orange and Roman Catholic factions. In 1746, however, he had to exchange the lord-lieutenancy for the office of Secretary of State. With a certain reserve for those theories his familiarity with the secret social history of France had caused him to entertain, he hoped and attempted to retain a hold over the king through the influence of Lady Yarmouth, though the futility of such means had already been demonstrated to him by his relations with Queen Caroline's "ma bonne H. award." The influence of Newcastle and Sandwich, however, was too strong for him; he was thwarted and over-reached; and in 1748 he resigned the seals, and returned to cards and his books with the admirable composure which was one of his most striking characteristics. He declined any knowledge of the Apology for a late Resignation, in a Letter from an English Gentleman to his Friend at the Hague, which ran through four editions in 1748, but there is little doubt that he was, at least in part, the author.

The dukedom offered him by George II., whose ill will his fine tact had overcome, was refused. He continued for some years to attend the Upper House, and to take part in its proceedings. In 1751, seconded by Lord Macclesfield, president of the Board of Trade, and Bradley, the eminent mathematician, he distinguished himself greatly in the debates on his calendar, and succeeded in making the new style a fact. Deafness, however, was gradually affecting him, and he withdrew little by little from society and the practice of politics. In 1755 occurred the famous dispute with Johnson over the dedication to the English Dictionary. In 1747 Johnson sent Chesterfield, who was then secretary of state, a prospectus of his Dictionary, which was acknowledged by a subscription of £10. Chesterfield apparently took no further interest in the enterprise, and the book was about to appear, when he wrote two papers in the World in praise of it. It was said that Johnson was kept waiting in the ante-room when he called while Cibber was admitted. In any case the doctor had expected more help from a professored patron of literature, and wrote the earl the famous letter in defence of men of letters. Chesterfield's "respectable Hottentot," now identified with George, Lord Lyttelton, was long supposed, though on slender grounds, to be a portrait of Johnson. During the twenty years of life that followed this episode, Chesterfield wrote and read a great deal, but went little into society.

In 1768 died the child of so many hopes. The constant care bestowed by the earl on his education resulted in an honourable but not particularly distinguished career for young Stanhope. His death was an overwhelming grief to Chesterfield, and the discovery that he had long been married to a lady of humble origin must have been galling in the extreme to his father after his careful instruction in worldly wisdom. Chesterfield, who had no children by his wife, Melusina von Schulemburg, illegitimate daughter of George I., whom he married in 1733, adopted his godson, a distant cousin, named Philip Stanhope (1755-1815), as heir to the title and estates. His famous jest (which even Johnson allowed to have merit)—
Tyraly and I have been dead these two years, but we don't choose to have it known!—"is the best description possible of his humor and condition during the latter part of this period of decline. To the deafness was added blindness, but his memory and his fine manners only left him with life; his last words ("Give Dayrolles a chair") prove that he had neither forgotten his friend nor the way to receive him. He died on the 24th of March 1773.

Chesterfield was selfish, calculating and contemptuous; he was not naturally generous, and he practised dissimulation till it became part of his nature. In spite of his brilliant talents and of the admirable training he received, his life, on the whole, cannot be pronounced a success. His anxiety and the pains he took to become an orator have been already noticed, and Horace Walpole, who had heard all the great orators, preferred a speech of Chesterfield's to any other; yet the earl's eloquence is not to be compared with that of Pitt. Samuel Johnson, who was not perhaps the best judge in the world, pronounced his manners to have been "exquisitely elegant," yet as a courtier he was utterly worsted by Robert Walpole, whose manners were anything but refined, and even by Newcastle. He desired to be known as a protector of letters and literary men; and his want of heart or head over the Grange life was shown. The Tory sympathies of the Crocker, none the less inspired the famous change in a famous line—"Toil, envy, want, the patron, and the jail." His published writings have had with posterity a very indifferent success; his literary reputation rests on a volume of letters never designed to appear in print. The son for whom he worked so hard and thought so deeply failed especially where his father had most doubt he should succeed.

As a politician and statesman, Chesterfield's fame rests on his short but brilliant administration of Ireland. As an author he was a clever essayist and epigrammatist. But he stands or falls by the Letters to his Son, first published by Stanhope's widow in 1774, and the Letters to his Godson (1806). The Letters are brilliantly written—full of elegant wisdom, of keen wit, of admirable portrait-painting, of exquisite observation and deduction. Against the charge of an undue insistence on the external graces of manner Chesterfield has been adequately defended by Lord Stanhope (History, iii. 34). Against the often iterated accusation of immorality, it should be remembered that the Letters reflected the deadening thought which explained and excused the conduct of which, deliberately or unconsciously, the best and the worst of his contemporaries were governed.

The earldom of Chesterfield passed at his death to his godson, already mentioned, as 5th earl, and so to the latter's son and grandson. On the death of the latter unmarried in 1871, it passed in succession to two collateral heirs, the 8th and 9th earls, and so in 1887 to the latter's son as 10th earl.

See Chesterfield's Miscellaneous Works (London, 1777, 2 vols. 4to); Letters to his Son, &c., edited by Lord Mahon (London, 1845-1853, 5 vols.); and Letters to his Godson (1806) (edited by the earl of Carnarvon). There are also editions of the first series of letters by J. Bradshaw (3 vols. 1802) and Mr C. Strachey (2 vols., 1901). In 1801 a biography, including numerous letters first published from the Newcastle Papers, was issued by Mr W. Ernst; and in 1907 appeared a volume by W. H. Craig (A. D.).

CHESTERFIELD, a market town and municipal borough in the Chesterfield parliamentary division of Derbyshire, England, 24 miles N. by E. of Derby, on the Midland and the Great Central railways. Pop. (1891) 22,000; (1901) 27,185. It lies at the junction of two streams, the Rother and Hipper, in a populous industrial district. It is irregularly built, with narrow streets, but has a spacious market-place. The church of St Mary and All Saints is a large and beautiful cruciform building principally of the Decorated period. Its central tower carries a remarkable twisted spire of wood covered with lead, 230 ft. high; the tracery has evidently taken place through the use of unseasoned timber and consequent warping of the woodwork. The church, which contains numerous interesting monuments, possesses also the unusual feature of an apsidal Decorated chapel. There is an example of flamboyant tracery in one of the windows. Among public buildings, the Stephenson memorial hall (1879), containing a free library, art and science class-rooms, a theatre and the rooms of the Chesterfield Institute, commemorates George Stephenson, the engineer, who resided at Tapton House, close to Chesterfield, in his later life; he died here in 1848, and was buried in Trinity church. Chesterfield grammar school was founded in 1574. The industries of the town include manufactories of cotton, silk, earthenware, machinery and tobacco, and brass and iron founding; while slate and stone are quarried, and there are coal, iron and lead mines in the neighbourhood. The town is governed by a mayor, 6 aldermen and 18 councillors. Area, 1216 acres. In the immediate neighbourhood of Chesterfield on the west is the urban district of Brampton and Walton (pop. 2698), to the south-east is Hasland (7427), and to the north-east Birkington (4506).

In spite of the Roman origin suggested by its name, so few remains have been found here that it is doubtful whether Chesterfield was a Roman station. Chesterfield (Cestrefeld) owes its present name to the Saxons. It is mentioned in Domesday only as a bailiwick of Newbold belonging to the king, and granted to William Feverell. In 1204 John gave the manor to William Bruere and granted to the town all the privileges of a free borough by charter. But this charter was not confirmed by King John, and before this it seems to have had prescriptive borough rights. Later charters were granted by various sovereigns, and it was incorporated by Elizabeth in 1598 under the style of a mayor, 6 brethren and 12 capital burgesses. This charter was confirmed by Charles II. (1662), and the town was so governed till the Municipal Act 1835 appointed a mayor, 3 aldermen and 12 councillors. In 1804 John granted two weekly markets, on Tuesday and Saturday, and an annual fair of eight days at the feast of the Exaltation of the Holy Cross (Sept. 14). This fair, which is still held, and another on Palm Tuesday, are mentioned in the Quo Warranto roll of 1330. The Tuesday market has long been discontinued. That Chesterfield was early a thriving centre is shown by the charter of John Lord Wake, lord of the manor, granting a guild merchant to the town. In 1266 the town was the scene of a battle between the royal forces and the barons, when Robert de Ferrers, earl of Derby, was taken prisoner. In 1266 there was a terrible visitation of the plague; and the parliamentary forces were overthrown here in the Civil War. With the development of the cotton and silk industries the town has increased enormously, and is now second in importance only to Derby among the towns of the county. There is no record that it ever returned representatives to parliament.

See Stephen Glover, History and Gazetteer of the County of Derby (Derby, 1831-1833); J. Pym Yeatman, Records of the Borough of Chesterfield (Chesterfield and Sheffield, 1884); Thomas Ford, History of Chesterfield (London, 1839).

CHESTER-LE-STREET, a town in the Chester-le-Street parliamentary division of Durham, England, near the river Wear, 6 m. N. of the city of Durham on the North-Eastern railway. Pop. (1901) 11,753. The parish church of St Mary and St Cuthbert is an interesting building, formerly collegiate, with a tower 156 ft. high, and a remarkable series of monumental tombs of the Lumley family, collected here from Durham cathedral and various ruined monasteries, and in some cases removed. About 1 m. along the river is Lumley Castle, the seat of the earl of Scarbrough, and about 2 m. north lies Wombwell Castle, the residence of the earl of Durham, built in 1797 on the site of the old House. The cotton and silk industries the town employs the industrial population. Chester-le-Street is a place of considerable antiquity. It lies on a branch of the Roman north road, on which it was a station, but the name is not known. Under the name of Canecastre it was made the seat of a bishop in 882, and continued to be the head of the diocese till the Danish invasion of 995. During that time the church was the repository of the shrine of St Cuthbert, which was then removed to Durham.

CHESTERTON, GILBERT KEITH (1874— ), English journalist and author, who came of a family of estate-agents, was born in London on the 29th of May 1874. He was educated
CHESTERTON—CHESTNUT

at St Paul's school, which he left in 1891 with the idea of studying art. But his natural bent was literary, and he devoted himself mainly to cultivating that means of expression by both in prose and verse; he did occasional reviewing, and had some experience in a publisher's office. In 1900, having already produced a volume of clever poems, The Wild Knight, he definitely took to journalism as a career, and became a regular contributor of signed articles to the Liberal journals, the Speaker and Daily News. He established himself from the first as a writer with a distinct personality, combative to a swashbuckling degree, unconventional and dogmatic; and the republication of much of his work in a series of volumes (e.g. Twelve Types, Heretics, Orthodoxy), characterized by much acuteness of criticism, a pungent style, and the capacity of laying down the law with unflagging impetuosity and humour, enhanced his reputation. His powers as a writer are best shown in his studies of Browning (in the "English Men of Letters" series) and of Dickens; but these were only rather more ambitious essays among a medley of characteristic utterances, ranging from fiction (including The Napoleon of Notting-hill) to fugitive verse, and from artistic criticism to discussions of ethics and religion. The interest excited by his work and views was indicated and analysed in an anonymous volume (G. K. Chesterton: a Criticism) published in 1909.

CHESTERTON, an urban district in the Chesterton parliamentary division of Cambridgeshire, England, 13 m. N. from Cambridge station, on the north bank of the Cam. (Pop. 1901) 9951. The church of St Andrew is Decorated and Perpendicular, retaining ancient woodwork and remains of fresco painting. Along the river are several boat-houses erected by the Cambridge University Boat Club. Boat-building and tile manufacture are local industries.

CHESTNUT (nux Castanea), the common name given to two sorts of trees and their fruit, (1) the so-called "horse-chestnut," and (2) the sweet or "Spanish" chestnut.

(1) The common horse-chestnut, Aesculus Hippocastanum (Ger. Rosskastanie; Fr. marronnier d'Inde), has been stated to be a native of Tibet, and to have been brought thence to England in 1550: it is now, however, thought to be indigenous in the mountains of northern Greece, where it occurs wild at 3000 to 4000 ft. above sea-level. Matthiolus, who attributes the origin of the name of the tree to the use of the nuts by the inhabitants of Constantinople for the relief of short-windedness and cough in horses, remarks that no ancient writer appears to have made mention of the horse-chestnut. Clusius (Corollarum Plantarum hist. i, 1587) describes it as a vegetable curiosity, of which he says, that in 1588 he had left in Vienna a living specimen, but which he had not yet seen either the flowers or recent fruit. The dry fruit, he says, had frequently been brought from Constantinople into Europe.

The tree grows rapidly; it flourishes best in a sandy, somewhat moist loam, and attains a height of 50 to 60 or more ft., assuming a pyramidal outline. Its boughs are strong and spreading. The buds, conspicuous for their size, are protected by a coat of a glutinous substance, which is impervious to water; in spring this melts, and the bud-scales are then cast off. The leaves are composed of seven radiating leaflets (long-wedge-shaped); when young they are downy and drooping. From the early date of its leafing year by year, a horse-chestnut in the Tulleries is known as the "Marronnier du 20 mars." The flowers of the horse-chestnut, which are white dashed with red and yellow, appear in May, and sometimes, but quite exceptionally, again in autumn; they form a handsome erect panicle, but comparatively few of them afford mature fruit. The fruit is ripe in or shortly before the first week in October, when it falls to the ground, and the three-valved thin-walled capsule divides, disclosing the brown and at first beautifully glossy seeds, the so-called nuts, having a resemblance to thistles, and containing horse-chestnuts, and commonly three or else two in number. For propagation of the tree, the seeds may be sown either when fresh, or, if preserved in sand or earth, in spring. Drying by exposure to the air for a month has been found to prevent their germination. Roots are wont to remove the nuts from the tree just before they fall, and to disperse them in various directions. The tree is rarely planted in mixed plantations where profit is an object; it interferes with its neighbours and occupies too much room. It is generally introduced near mansion-houses for ornament and shade, and the celebrated avenues at Richmond and Bushey Park in England are objects of great beauty at the time of flowering.

The bark of the horse-chestnut contains a greenish oil, resin, a yellow body, a tannin, C6H5O3, existing likewise in the seeds and various parts of the tree, and decomposable into phloroglucin and aesciglycolic acid, C6H6O2, also aesculetin hydrate, and the crystalline fluorescent compound aesculin, of the formula C6H4O2 (Rochleder and Schwarz), with which occurs a similar substance fraxin. the paviin of Sir G. G. Stokes (Q. J. Chem. Soc. xi. 17, 1859; xii. 126, 1860), who suggests that its presence may perhaps account for the discrepancies in the analyses of aesculin given by different authors. From the seeds have been obtained starch (about 14%), gum, mucilage, a non-drying oil, phosphoric acid, salts of calcium, saponin, by boiling which with dilute hydrochloric or sulphuric acid aesculin is obtained, quercitrin, present also in the fully developed leaves, aescigenin, C6H4O2, and aesculetin, C8H4O3, which is procurable also, but in small quantity only, from the bark. Friedrich Rochleder has described as constituent principles of the cotyledons sphyrodaesin, C6H6O3, a bitter glucosidic substance, C6H4O3, aescin acid, C8H4O3, and quercitin, C6H5O3, found also in the leaves. To prepare pure starch from the seeds, Flandin (Compt. rend. xxvii. 391, 1859; xxviii. 138, 1849) recommends kneading them, and peeled and bruised, in an aqueous solution of 1/3% to 3% of their weight of sodium carbonate. E. Staffel (Ann. d. Chem. u. Pharm. lixxvi., 1850, p. 379) after drying found, in spring and autumn respectively, 9-0 and 3-38% of ash in the wood, 6-86 and 6-57 in the bark, and 7-68 and 7-52 in the leaves of the horse-chestnut. The ash of the unripe fruit contains 38-77%, that of the ripe kernel 61-74, and that of the green shell 75-91% of potash (E. Wolff).

The wood of the horse-chestnut is soft, and serves only for the making of water-pipes, for turner’s work and common carpentry, as a source of charcoal for gunpowder, and as fuel. New cut it weighs 60 lb., and dry 35 lb per cwt. approx.

The bark has been employed for dyeing yellow and for tanning, and was formerly in popular repute as a febrifuge and tonic. The powder of the dried nuts was at one time prescribed as a sternutatory (to encourage sneezing) in the Edinburgh Pharmacopoeia. It is stated to form with alum-water a size or cement highly offensive to vermin, and with two parts of wheat flour a material for making a powder, known as Brecknock. Injury of horse-chestnuts is found to expel worms from soil, and soon to kill them if they are left in it. The nuts furthermore have been applied to the manufacture of an oil for burning, cosmetic preparations and starch, and in Switzerland, France and Ireland, when rapped on ground, to the bleeding of flax, hemp, silk and wool. In Geneva horse-chestnuts are largely consumed by grazing stock, a single sheep receiving 2 lb. crushed morning and evening. Given to cows in moderate quantity, they have been found to enhance both the yield and flavour of milk. Deer readily eat them, and, after a preliminary steeping in lime-water, pigs also. For poultry they should be used boiled, and mixed with other nourishment. The fallen leaves are relished by sheep and deer, and afford a good litter for flocks and herds. Various horse-chestnut has variegated leaves, and another double flowers. Darwin observed that Aesculus, the red buckeye of North America, shows a special tendency, under unfavourable conditions, to be double-blossomed. The seeds of this species are used to stupefy fish. The scarlet-flowered horse-chestnut, Aesculus rubicunda, is a handsome tree, less in height and having a rounder bough than the common form; it is a native of North America. Another species, possessing flowers with the lower petals white with a red tinge, and the upper yellow and red with a white border, and fruit unarmed, is Aesculus indica, a native of the western Himalayas. Among the North American species are the footed or Ohio buckeye, Aesculus octandra, and Aesculus flava, the sweet
buckeye, *Ac. californica*, when full-grown and in flower, is a beautiful tree, but its leaves often fall before midsummer.

(x) The Spanish or sweet chestnut, *Castanea sativa* (natural order, Fagaceae), is a stately and magnificent tree, native of the countries bordering on the Mediterranean, but also ripening its fruit in sheltered situations as far north as Scotland. It lives very long, and attains a large size, spreading its branches widely. It has large glossy lanceolate leaves with a toothed margin. The flowers, which appear in early summer, are in pendulous, slender yellowish catkins, which bear a number of staminate flowers with a few pistillate flowers at the base. The staminate contain 8 to 20 stamens which produce an enormous amount of dusty yellow pollen, some of which gets carried by wind to the protruding stigmas of the pistillate flowers. The latter are borne three together, invested by a cupule of four green bracts, which, as the fruit matures, grow to form the tough green prickly envelope surrounding the group of generically three nuts. The largest known chestnut tree is the famous Castagno di cento cavali, or the chestnut of a hundred horses, on the slopes of Mount Etna, a tree which, when measured about 1780 by Count Borch, was found to have a circumference of 100 feet. The tree bears a striking resemblance to that of oak, which has been mistaken for chestnut; but it may be distinguished by the numerous fine medullary rays. Unlike oak, the wood is more valuable while young than old. When not more than fifty years old it forms durable posts for fences and gates; but at that age it often begins to deteriorate, having ring-shakes and central hollows. In a young stage, when the stems are not above 2 in. in diameter at the ground, the chestnut is found to make durable hoops for casks and props for vines; and of a larger size it makes good hop-poles.

Chestnuts (the fruit of the tree) are extensively imported into Great Britain, and are eaten roasted or boiled, and mashed or otherwise as a vegetable. In a raw state they have a sweet taste, but are difficult of digestion. The trees are very abundant in the south of Europe, and chestnuts bulk largely in the food resources of the poor in Spain, Italy, Switzerland and Germany. In Italy the kernels are ground into meal, and used for thickening soups, and even for bread-making. In North America the fruits of an allied species, *C. americana*, are eaten both raw and cooked.

**CHETTE, HENRY** (1567–1607), English dramatist and miscellaneous writer, was the son of Robert Chettle, a London dyer. He was apprenticed in 1577 to a stationer, and in 1591 became a partner with William Hoskins and John Danter. In 1592 he published Robert Greene’s *Groatworth of Wit*. In the preface to his *Kind Herts Dreame* (end of 1592) he found it necessary to disavow any share in that pamphlet, and incidentally he apologized to three persons (one of them commonly identified with Shakespeare) who had been abused in it. *Piers Plainez Steven Yeres Prentiship*, the story of a fictitious apprenticeship in Crete and Thrace, appeared in 1595. As early as 1598 Francis Meres includes him in his *Palatius Tamia* as one of the “best for comedy,” and between that year and 1603 he wrote or collaborated in some forty-nine pieces. He seems to have been generally in debt, judging from numerous entries in Henslowe’s diary of advances for various purposes, on one occasion (17th of January 1599) to pay his expenses in the Marshalsea prison, on another (7th of March 1603) to get his play out of pawn. Of the thirteen plays usually attributed to Chettle’s supposed authorship only one was printed. This was *The Tragedy of Hoffmann or Revenge for a Father* (played 1602; printed 1631), a share in which Mr. Fleay assigns to Thomas Heywood. It has been suggested that this piece was put forward as a rival to Shakespeare’s *Hamlet*. Among the plays in which Chettle had a share is catalogued *The Danish Tragedy*, which was probably either identical with Hoffmann or another version of the same story. *The Pleasant Comedie of Patient Grissill* (1590), in which he collaborated with Thomas Dekker and William Haughton, was reprinted by the Shakespeare Society in 1841. It contains the lyric “Art thou poor, yet hast thou golden slumbers,” which is probably Dekker’s. In November 1599 Chettle receives ten shillings for mending the first part of “Robin Hood,” *i.e.* *The Downfall of Robert, Earl of Huntington*, by Anthony Munday; and in the second part, which followed soon after and was printed in 1601, *The Death of Robert, Earl of Huntington*, he collaborated with Munday. Both plays are printed in Dod’s *Select Collection of Old English Plays* (ed. W. C. Hazlitt, vol. vii.). In 1603 Chettle published *England’s Mourning Garment*, in which are included some verses alluding to the chief poets of the time. His death took place before the appearance of Dekker’s *Knight’s Conjuror* in 1607, for he is there mentioned as a recent arrival in limbo.

Hoffmann was edited by H. B. Barrett L’ennard (1852) and by Richard Ackermann (Banberg, 1894).

**CHEVALIER, ALBERT** (1861—), English comedian, began a connexion with the stage while still a child. In 1877 he was engaged as an actor under the Bancrofts in London, and for some years played “legitimate” parts at the Court theatre and elsewhere. In 1891, however, he began a successful music-hall career as a singer of coster songs of his own invention, a new type in which he had an immediate success, both in England and America. He subsequently organized an entertainment of his own, with sketches and songs, with which he went on tour, establishing himself as a popular original artist in his special line.

**CHEVALIER, MICHEL** (1866–1879), French economist, was born at Limoges on the 13th of June 1826. In his early manhood, while employed as an engineer, he became acquainted with the theories of Saint Simon; these he ardently advocated in the *Globe*, the organ of the Saint Simonians, which he edited until his arrest in 1832 on a charge of outraging public morality by its publication. He was sentenced to a year’s imprisonment, but was released in six months through the intervention of Thiers, who sent him on a special mission to the United States to study the question of land and water transport. In 1836 he published, in two volumes, the letters he wrote from America to the *Journal des débats*. These attracted so much attention that he was sent in the same year on an economic mission to England, which resulted in his publication (in 1838) of *Des intérêts matériels de la France*. The success of this made his position secure, and in 1840 he was appointed professor of political economy in the Collège de France. He sat for a short time (1845–1846) as a member of the Chamber of Deputies, but lost his seat owing to his enthusiastic adoption of the principles of free trade. Under Napoleon III. he was restored to the position of which the revolution of 1848 had temporarily deprived him. In 1850 he became a member of the Institute, and in the following year published an important work in favour of free trade, under the title of *Examen du système commercial connu sous le nom de système protecteur*. His chief public triumph was the important part he played in bringing about the conclusion of the commercial treaty between France and Great Britain in 1860. Previously to this he had served, in 1855, upon the commission for organizing the Exhibition of 1855, and his services there led to his forming one of the French jury of awards in the London Exhibition of 1862. He was created a member of the Senate in 1866, and continued for some years to take an active part in its discussions. He retired from public life in 1870, but was unceasingly industrious with his pen. He became grand officer of the Legion of Honour in 1861, and during the later years of his life received from many quarters public recognition of his eminence as a political economist. He died at his chateau near Montpellier (Hérault) on the 28th of November 1881. Many of his works have been translated into English and other languages. Besides those already mentioned the most important are: *Cours d'économie politique* (1842–1850); *Essais de politique industrielle* (1843); *De la baisse probable d'or* (1859, translated into English by Cobden, *On the Probable Fall of the Value of Gold*, Manchester, 1859); *L'Expédition du Mexique* (1862); *Introduction aux rapports du jury international* (1868).

**CHEVALIER, ULYSSE** (1841—), French bibliographer, was born at Rambouillet on the 24th of February 1841. He published a great number of documents relating to the history of Dauphiné, *e.g.* the cartularies of the church and the town of Die (1868), of the abbey of St André le-Bas at Vienne (1860), of the abbey of Notre Dame at Bonnevaux in the diocese of Vienne (1889), of the abbey of St Chaffe at Le Monestier (1884), the
inventories and collections of archives of the dauphins of Viennais, and a Bibliothèque liturgique in six volumes (1893–1897), the third and fourth volumes of which constitute the Repertorium hymnologicum, containing more than 20,000 hymns. His principal work was the Répertoire des sociétés historiques du monde. The first part, Bio-bibliographie (1877–1886; 2nd ed., 1905), contains the names of all the historical personages alive between the years 1 and 1500 who are mentioned in printed books, together with the precise indication of all the places where they are mentioned. The second part, Topo-bibliographie (1804–1903), contains not only the names of places mentioned in books on the history of the middle ages, but, in a general way, everything not included in the Bio-bibliographie. The Répertoire as a whole contains an enormous mass of useful information, and is one of the most important bibliographical monuments ever devoted to the study of medieval history. Though a Catholic priest and professor of history at the Catholic university of Lyons, the Abbé (afterwards Canon) Chevalier knew how to maintain an independent critical attitude even in religious questions. In the controversy on the authenticity of the Holy Shroud (sudario) at Turin, he worked in the true scientific spirit by tracing back the history of that piece of stuff, which was undoubtedly used as a shroud, but which was not produced before the 14th century and is probably no older (See Le Saint Suaire de Lirey-Chambery- Turin et les défenseurs de son authenticité). Similarly, in Notre Dame de Lorette; Étude critique sur l'authenticité de la Santa Casa (1906), he dissipated by the aid of authentic documents the legend of the “sudario” which had embellished and falsified the primitive history of that sanctuary.

CHEVAUX-DE-FRISÉ—CHEVIOT HILLS

(CHEVAUX-DE-FRISÉ— CHEVIOT HILLS

French for “Friesland horses”; the Dutch Vriese ruyters, “Frisian horsemen,” and German Spanische Reiter, “Spanish horsemen”), a military obstacle, originating apparently in the Dutch War of Independence, and used to close the breach of a fortress, streets, &c. It was formerly often used in field operations as a defence against cavalry; hence the name, as the Dutch were weak in the mounted arm and had therefore to check the enemy’s cavalry by an artificial obstacle. Chevaux-de-frise consist of beams in which are fixed a number of spears, sword-blades, &c., with the points projecting outwards on all sides.

CHEVERUS, JEAN LOUIS ANNE MAGDELEINE LEFEBVRE DE (1768–1830), French ecclesiastic, was born on the 28th of January 1768, in Mayenne, France, where his father was general civil judge and lieutenant of police. He studied at the college of Mayenne, received the tonsure when twelve, became prior of Torbecuet while still little more than a child, thence derived sufficient income for his education, entered the College of Louis le Grand in 1785, and after completing his theological studies at the Seminary of St Magloire, was ordained deacon in October 1790, and priest by special dispensation on the 18th of December. He was immediately made canon of the cathedral of Le Mans and began to act as vicar to his uncle in Mayenne, who died in 1792. Owing to the progress of the Revolution he emigrated in 1790 to England, and thence in 1796 to America, settling in Boston, Mass. His interest had been aroused by François Antoine Matignon, a former professor at Orleans, now in charge under Bishop John Carroll of all the Catholic churches and missions in New England. Cheverus, although at first appointed to an Indian mission in Maine, remained in Boston for nearly a year, and returned thither after several months in the Penobscot and Passamaquoddy missions and visits to scattered Catholic families along the way. During the epidemic of yellow fever in 1798 he won great praise and respect for his courage and charity; and his preaching was listened to by many Protestants—a thing unnecessary for his subscriptions for the Church of the Holy Cross which he founded in 1803 were largely from non-Catholics. In 1808 the papal brief was issued making Boston a diocese, suffragan to Baltimore, and Cheverus his bishop. He was consecrated on All Saints’ Day in 1810, at St Peter’s, Baltimore, by Archbishop Carroll. On the death of the latter his assistant bishop, Neale, urged the appointment of Cheverus as assistant to himself; Cheverus refused and warmly asserted his desire to remain in Boston; but, much broken by the death of Matignon in 1818 and with impaired health, he soon found it necessary to leave the seat of his bishopric. In 1823, Louis XVIII. having insisted on his return to France, Cheverus became bishop of the island of Orleans, his residence captivating the Protestant clergy and laity of the city. He was installed bishop of Bordeaux in 1826; and on the 1st of February 1836, in accordance with the wish of Louis Philippe, he was made a cardinal. He died in Bordeaux on the 19th of July 1836. To Cheverus, more than to any other, is due the position that Boston now holds in the Roman Catholic Church of America, as well as the general growth of that church in New England. His character was essentially lovable: the Jews of Bordeaux and Protestants everywhere delighted to honour him.

See the rather extravagant biography by J. Huc-Dubourg, Vie du cardinal de Cheverus (Bordeaux, 1838; English version by E. Stewart, Boston, 1839).

CHEVET, the term employed in French architecture to distinguish the apsidal end of a church, in which the apses or Chapels radiate round the choir aisle. The two earliest examples (11th and 12th century) are found in the churches of St Hilaire, Poitiers, and Notre Dame-du-Port, Clermont, where there are four apses. A more usual number is five, and the central apse, being of larger dimensions, becomes the Lady chapel. This was the case in Westminster Abbey, where Henry III. introduced the chevet into England; Henry VII.’s chapel is built on the site of the original Lady chapel, which must have been of exceptional size, as it extended the whole length of the present structure. In Solignac, Fouteuvaill and Paray-le-Monial there are three, in these cases sufficiently distant one from the other to allow of a window between. The usual number in all the great cathedrals of the 13th century, as in Bourges, Chartres, Reims, Troyes, Tours, Bayeux, Antwerp and Bruges, is five. In Beauvais, Amiens and Cologne there are seven apsidal chapels, and in Clairvaux nine radiating but rectangular chapels. In the 14th and 15th centuries the central apse was increased in size and dedicated to the Virgin Mary, as in St Ouen at Rouen.

CHEVIOT HILLS, a range forming about 35 m. of the border between England and Scotland. The boundary generally follows the line of greatest elevation, but as the slope is more gradual southward and northward the larger part of the range is in Northumberland, England, and the lesser in Roxburghshire, Scotland. The axis runs from N.E. to S.W., with a northward tendency at the eastern end, where the ridge culminates in the Cheviot, 2675 ft. Its chief elevations from this point southward fall abruptly to 2034 ft. in Windgate Hill, and then more gradually to about 1600 ft. above the pass, followed by a high road from Redesdale. Beyond this are Carter Fell (1815) and Peel Fell (1864), after which two lines of lesser elevation branch southward to include Liddledale. The hills are first crossed by the Jed Water and the Edgerton Burn and is bounded by rocks of Old Red Sandstone age. The strata consist of greywackes, flags and shales with seams and zones of grapholite shale which yield fossils sparingly.

Geology.—The rocks entering into the geological structure of the Cheviots belong to the Silurian, Old Red Sandstone and Carboniferous systems. The oldest strata, which are of Upper Silurian age, form cliffs that have been exposed by the denudation of the younger palaeozoic rocks. On the lower cliffs and on the top of the Cheviots the sky is covered by the river Coquet and with the river Tyne and the Tweed towards the north by the Old Red Sandstone volcanic series on the south by Carboniferous strata. Another stratum is traversed by the Jed Water and the Edgerton Burn and is bounded by rocks of the Old Red Sandstone age. The strata consist of greywackes, flags and shales with seams and zones of grapholite shale which yield fossils sparingly.
On the upturned and denuded edges of the Silurian strata a great pile of contemporaneous volcanic rocks of Lower Old Red Sandstone age rests unconformably, which consists chiefly of lavas with thin partings of tuff. A striking feature is the absence of coarse sediments, thus indicating prolonged volcanic activity. They cover an area of about 250 sq. m. in the eastern part of the Cheviots and rise to a height of 2676 ft. above the sea. The lavas comprise dark pitchstone, resembling that at Kirk Yetholm, and porphyritic and amygdaloidal andesites and basalts. This volcanic platform is pierced by dykes of granite about 20 sq. m. in extent, which forms the highest peak in the Cheviot range. It has been described by Dr Teall as an augite-biotite-granite having strong affinities with the augite-bearing granitoids of Laveline and Oberbrück in the Vosges.

On their north-west margin the Lower Old Red volcanic rocks are separated from the conglomerate and sandstone by the upper division of that system composed of red sandstones and conglomerates, which, when followed westwards, rest directly on the Silurian platform. Towards the south and east the volcanic pile is overlaid by Carboniferous strata, thus indicating a prolonged interval of denudation.

On the northern slopes of the western part of the Cheviots the representatives of the Cementstone group of the Carboniferous system come to the surface, where they consist of shales, clays, mudstones, sandstones with cementstones and occasional bands of marine limestone. These are followed in normal order by the Fell Sandstone group, comprising a succession of sandstones with intercalations of red and green clays and impure cementstone bands. These pass down to the lower part of the Larriston sands and are traceable eastwards to Peel Fell, where there is evidence of successive land surfaces in the form of dirt beds. They are succeeded by the Lewisburn coal-bearing group, which represents the Scremerston coals.

CHEVREUL, MICHEL EUGÈNE (1786-1889), French chemist, was born, on the 31st of August 1786, at Angers, where his father was a physician. At the age of seventeen he went to Paris and entered L. N. Vauquelin’s chemical laboratory, afterwards becoming his assistant at the natural history museum in the Jardin des Plantes. In 1813 he was appointed professor of chemistry at the Lycée Charlemagne, and subsequently undertook the directorship of the Gobelin’s tapestry works, where he carried out his researches on colour contrasts (Le contraste simultané des couleurs, 1830). In 1826 he became a member of the Academy of Sciences, and in the same year was elected a foreign member of the Royal Society of London, whose Copley medal he was awarded in 1857. He succeeded his master, Vauquelin, as professor of organic chemistry at the natural history museum in 1830, and thirty-three years later assumed its directorship also; he relinquished in 1879, though he still retained his professorship. In 1886 the completion of his hundredth year was celebrated with public rejoicings; and after his death, which occurred in Paris on the 9th of April 1889, he was honoured with a public funeral. In 1901 a statue was erected to his memory in the museum with which he was connected for so many years. His scientific work covered a wide range, but his name is best known for the classical researches he carried out on animal fats, published in 1823 (Recherches sur les corps gras d’origine animale). These enabled him to elucidate the true nature of soap; he was also able to discover the composition of stearin and olein, and to isolate stearic and oleic acids, the names of which were invented by him. This work led to important improvements in the processes of candle-manufacture. Chevreul was a determined enemy of charlatanism in every form, and a complete sceptic as to the “scientific” psychological research or spiritualism which had begun in his time (see his De la baguette divinatoire, et des tables tournantes, 1864).

CHEVRON (Fr. from chèvre, a goat), in architecture, the beams or rafters in the roofs of a building, meeting in an angle with a fancied resemblance to the horns of a butting goat; in heraldry a bent bar on a shield, used also as a distinguishing badge of rank on the sleeves of non-commissioned officers in most armies and navies and by police and other organized bodies wearing uniform, and as a mark of good conduct in the army and navy. Chevrons are generally used in the term for an inscribed pattern laid on a surface, called also “zig-zag,” found largely in Romanesque architecture in France, England and Sicily. It is one of the most common decorations found in the vouchsafes of the Norman arch, and was employed also on shafts, as in the cloisters of Monreale near

Palermo, those of St Paul outside Rome, and many churches in Germany. Its earliest appearance was in the tomb of Agamemnon at Mycenae, where the shafts flanking the entrance doorway have nine decorative chevron bands; in this case there is no doubt it was derived from the metal casing of the early wood columns.

CHEVROtain, a name taken from the French to designate the various representatives of the mammalian ungulate family Tragulidae. These tiny animals, commonly known as mouse-deer, are in no wise nearly related to the true deer, but constitute by themselves a special section of artiodactyle ungulates known as Tragulina, for the characteristics of which see Artiodactyla. The typical genus Tragulus, which is Asiatic, contains the smallest representatives of the family, the animals having more of the general aspects and habits of some rodents, such as the agoutis, than of other ruminants. The longest-known species are T. javanicus, T. napu, T. konchil, T. stanleyanus and T. memminna; but a number of other forms, best regarded for the most part as races, have been named. Of those mentioned, the first four are from the Malay Peninsula or the islands of the Indo-Malay Archipelago, the last from Ceylon and India. Konchil and napu (or napok) are the Malay names of the species with those specific titles. The second genus, Dorcatherium (or Hyemoschus), is African, and distinguished chiefly by the feet being stouter and shorter, the outer toes better developed, and the two middle metacarpals not welded together. Its dental formula (as that of Tragulus) is i. 3, c. 1, p. 3, m. 34. Vertebrae: C. 7, D. 13, L. 5, S. 5, C. 12-13. The only existing species, D. aequicuaum (fig.), in type is rather larger than any of the Asiatic chevrotains, which it otherwise much resembles, but is said to frequent the banks of streams, and have much the habits of pigs. It is of a rich brown colour, with back and sides spotted and striped with white; and it is evidently the survivor of an ancient form, as remains of a species only differing in size (D. crassum) have been found in the Miocene deposits of France. For long this species was supposed to be restricted to West Africa, but it has recently been obtained in East Central Africa, where it is represented by a local race.

CHEYENNE (Sioux for “of alien speech”), a tribe of North American Indians of Algonquian stock. They formerly lived on the Cheyenne river, North Dakota. Driven west by the Dakotas, they were found by early explorers at the eastern base of the Black Hills, South Dakota. Part of them later moved south and allied themselves with the Arapahoes. Their whole history has been one of war with their red and white neighbours. They are a powerful athletic race, mentally superior to the average American Indian. They are divided into eleven subdivisions and
formerly had a council of chiefs. They number some 3000, and are divided into northern and southern Cheyennes, the former being on a reservation in Montana, the latter in Oklahoma. In 1878-79 a band of the former revolted, and some seventy-five of them were killed.

See Handbook of American Indians (Washington, 1907); also Indians, North American.

CHEYENNE, the chief city and capital of Wyoming, U.S.A., and county-seat of Laramie county, on Crow Creek, about 106 m. N. of Denver. Pop. (1890) 11,690; (1900) 14,087, of whom 1961 were foreign-born; (1905) 13,656; (1910) 11,320. It is served by the Union Pacific, the Chicago, Burlington & Quincy, and the Colorado & Southern railways. It is situated near the southern boundary of the state, on the high plains near the E. foot of the Laramie range, at an altitude of 6030 ft.; the surrounding country is given up to mining (lignite and iron), grazing and dry-farming. Among the principal buildings are the capitol, modelled after the National Capitol at Washington; the United States government building; the Soldiers' and Sailors' Home, the Union Pacific depot, the high school, the Carnegie library, St. Mary's cathedral (Roman Catholic), the Convent of the Holy Child Jesus, the Masonic Temple and the Elks' club-house. The city has two parks, and is connected by a boulevard with Fort D. A. Russell, an important United States military post, 4 m. north of the city, established in 1867 and named in honour of Major-General David Allen Russell (1820-1864) of the Union army, who was killed at Opequon, Virginia. The industrial prosperity of Cheyenne is largely due to the extensive railway shops of the Union Pacific situated here; but the city is also an important cattle market and has stock-yards. In 1905 the value of the city's factory products ($924,697) was almost one-fourth the total value of the factory products of the state. Cheyenne, settled in 1869, when the Union Pacific reached here, was named from the Cheyenne Indians. It was chosen as the site for the capital of the territory in 1869, and was incorporated in the state in 1881. The Cheyenne tribe was originally connected with the Mandan and the Arikara tribes, but had long been exterminated, in 1867, by the settlers. 

CHEYENNE, THOMAS KELLY (1841- ), English divine and Biblical critic, was born in London, and educated at Merchant Taylors' School and Oxford. Subsequently he studied German theological methods at Göttingen. He was ordained in 1864, and held a fellowship at Balliol College, Oxford, 1868-1882. During the earlier part of this period he stood alone in the university as a teacher of the main conclusions of modern Old Testament criticism. In 1881 he was presented to the rectory of Tendring, in Essex, and in 1884 he was made a member of the Old Testament revision company. He resigned the living of Tendring in 1885 on his appointment to the Oriel professorship, which carried with it a canonry at Rochester. In 1889 he delivered the Bampton lectures at Oxford. In 1906 he resigned his professorship. He consistently urged in his writings the necessity of a broad and comprehensive study of the Scriptures in the light of literary, historical and scientific considerations. His publications include various addresses on the Prophets and Hagariana, and lectures and addresses on theological subjects. He was a joint editor of the Encyclopaedia Biblica (London, 1899-1903), a work embodying the more advanced conclusions of English biblical criticism. In the introduction to his Origin of the Psalter (London, 1891) he gave an account of his development as a critical scholar.

CHÉZY, ANTOINE LÉONARD DE (1773-1832), French orientalist, was born at Neuilly on the 13th of January 1773. His father, Antoine de Chézy (1717-1798), was an engineer who finally became director of the École des Ponts et Chaussées. The son was intended for his father's profession; but in 1799 he obtained a post in the oriental department of the national library. About 1805 he began the study of Sanskrit, though he possessed neither grammar nor dictionary, and by great labour he obtained sufficient knowledge of the language to be able to compose in it verses of which he himself possessed great elegance. He was the first professor of Sanskrit appointed in the Collège de France (1813), a chevalier of the Legion of Honour, and a member of the Académie des Inscriptions. He died in 1832. Among his works were  Méditations à Léila (1807), from the Persian; Yadvymadita Badha (1814) and La Reconnaissance de Sacsonval (1830), from the Sanskrit; L'Anthologie érotique d'Amour (1831), published under the pseudonym of Apudy. See the Mémoires of the Académie des Inscriptions (new series, vol. xii.), where there is a notice of Chézy by Silvestre de Sacy.

CHHATARPUR, a native state in the Bundelkhand agency of Central India. Area, 1,118 sq. m.; pop. (1901) 156,139; estimated revenue, £16,000. The chief, whose hereditary title is raja, is a Rajput of the Pounwar clan, whose ancestorpossessed the descendant of Chhatar sal, the founder of Bundelkhand independence, towards the end of the 15th century. The state was guaranteed to Kunwar Sunji Singh Pounwar in 1856. In 1854 it would have lapsed to the British government for want of direct heirs, but was conferred on Jagat Raj as a special act of grace. The town of Chhatarpur, which is named after Chhatar sal, and contains his cenotaph, is 70 m. by road S. W. of Banda. Pop. (1901) 10,029. There are manufactures of paper and coarse cutlery, and a high school. The state also contains the British cantonment of Nowgong.

CHHATTISGARH, a division of the Central Provinces of India, comprising a British division (21,240 sq. m.) and two small feudatory states, Raigarh (1486 sq. m.) and Saranggarh (540 sq. m.). In 1905 the five Oryia states of Bamra, Raiakhol, Sonpur, Patna and Kalashandi were transferred from the Central Provinces to Bengal. Chhattisgarh, or "the thirty-six forts," is a low-lying plain, enclosed on every side by hills and forests, while a rocky barrier shuts it off from the Nagpur plain on the west. Two great rivers, the Nerbudda and Sone, take their rise at the side of the Amarkantak hill in the north-west corner of the division, the Nerbudda flowing nearly due west to the Bombay coast, the Sone ultimately falling into the Ganges in Lower Bengal. Protected on both sides by ranges of hills, the district was, until late years, the least known portion of the most obscure division of India, but recently it has been opened up by the construction of a great railway and has developed into a great grain-producing country. Its population is almost pure Hindu, except in the two great tracts of hill and forest, where the aboriginal tribes retired before the Aryan invasion. It remained comparatively unaffected either by the Oryia immigration on the east, or by the later influx of Mahrots on the west. For though the Mahrots conquered and governed the country for a period, they did not take possession of the land. In 1901 the population of the two remaining feudatory states was 125,281, Raigarh having 86,543 and Saranggarh 38,738. Much of the soil is still covered with forest, but it includes fertile rice land.

The British division of Chhattisgarh comprises the three districts of Drug (created in 1906), Raipur and Bilaspur. In 1905 the district of Sambalpur, together with the five feudatory states, was transferred to Bengal. In 1901 the population of the reduced area was 2,642,983.

CHHINDWARA, a town and district of British India, in the Nerbudda division of the Central Provinces. The site of the town is 2200 ft. above sea-level, and is surrounded by ranges of low hills. The European station extends for nearly 2 m. and is well wooded. It is considered very healthy, and forms a resort for European visitors from Nagpur and Kampti during the hot weather.

The area of the District of Chhindwara is 4631 sq. m. It has two natural subdivisions—the hill country above the slopes of the Satpura mountains, called the Balaghat, and a tract of low land to the south called the Zergath. The high tableland of the Balaghat lies for the most part upon the great basaltic formation which stretches across the Satpuras as far east as Jubulpore. The country consists of a regular succession of hills and fertile valleys, formed by the small ranges which cross its surface east and west. The average height of the uplands is 3500 ft., but there are many points of greater elevation. The appearance of the Zergath below the hills is generally open and undulating. The country is intersected by several streams, of which the Kanhan is the most considerable. Near the hills and along the streams are strips and patches of jungle; the villages are usually surrounded...
with picturesque groves of tamarind, mango and other shade-giving trees. In the hill-country the climate is temperate and healthy. In the cold season ice is frequently seen in the small tanks at an elevation of about 2000 ft. Until May the hot wind is little felt, while during the rains the weather is cool and agreeable. The average annual rainfall amounts to 36 in. Pop. (1901) 497,027. There are manufactures of cotton cloth and brass-ware. Coal in this neighbourhood began to be worked after the opening of a branch of the Bengal-Nagpur railway to Chhindwara and the coalfields to the north in 1905. Chhindwara formed part of the dominions of the ancient Gond dynasty of Chhindwara and Nagpur, whose seat was at Deogarh until, in the 18th century, it was removed by Chand Sutan, son of Bakht Buland (founder of the short-lived greatness of the dynasty, and of the city of Nagpur) to Nagpur (see GONDWANA and NagPUR).

CHIABRERA, GABRIELO (1552-1637), Italian poet, sometimes called the Italian Pindar, was of patrician descent, and was born at Savona, a little town in the domain of the Genoese republic, twenty-eight years after the birth of Ronsard, with whom he has far more in common than with the great Greek whose echo he sought to make himself. As he has told in the pleasant fragment of autobiography prefixed to his works, in which, like Caesar, he speaks of himself in the third person, he was a posthumous child; he went to Rome at the age of nine years, under the care of his uncle Giovanni. There he read with a private tutor, suffered severely from two fever in succession, and was sent at last, for the sake of society, to the Jesuits' College, where he remained till his twentieth year, studying philosophy, as he says, “più per trattenimento che per apprendere,” rather for occupation than for learning's sake. Losing his uncle about this time, Chiabrera returned to Savona, “again to see his own and be seen by them.” In a little while, however, he returned to Rome, and entered the household of a cardinal, where he remained for several years, frequenting the society of Paulus Manutius and of Sperone Speroni, the dramatist and critic of Tasso, and attending the lectures and hearing the conversations of Muretto. His revenge of an insult offered him obliged him to betake himself once more to Savona, where, to amuse himself, he read poetry, and particularly Greek. The poets of his choice were Pindar and Anacreon, and these he studied till it grew to be his ambition to reproduce in his own tongue their rhythms and structures, and so to enrich his country with a new form of verse—in his own words, “like his countryman, ColumELus, to find a new world or drown.” His reputation was made at once; but he seldom quitted Savona, though often invited to do so, saving for journies of pleasure, in which he greatly delighted, and for occasional visits to the courts of princes whither he was often summoned, for his verse's sake, and in his capacity as a dramatist. At the ripe age of fifty he took to himself a wife, one Lelina Pavese, by whom he had no children. After a simple and blameless life, during which he produced a vast quantity of verse—epic, tragic, pastoral, lyrical and satirical—he died in 1637, at the patriarchal age of eighty-three. An epitaph in his memory was composed by Urban VIII.; but his tombstone are graven two quaint Italian hexameters of his own, in which the gazer is warned from the poet's own example not to prefer Parnassus to Calvary.

A maker of odes in all their elaborate pomp of strophe and antistrophe, a master of new and complex rhymes, a coiner of ambitious words and composite epithets, an employer of audacious transpositions and inversions, and the inventor of a new system of poetic diction,—it is not surprising that Chiabrera should have been compared with Ronsard. Both were destined to suffer eclipse as great and sudden as had been their glory. Ronsard was succeeded by Malherbe and by French literature, properly so-called; Chiabrera was the last of the great Italians, and after him literature languished till the second renaissance under Manzoni. Chiabrera, however, was a man of merit, apart from that of the mere innovator. Setting aside his epics and dramas (one of the latter received the honours of translation at the hands of Nicolas Chrétién, a sort of scenic du Bartas), much of his work remains yet readable and pleasant. His grand Pindarics are dull, it is true, but some of his Camonette, like the anacreontics of Ronsard, are exceedingly elegant and graceful. His autobiographical sketch is also extremely interesting. The simple old poet, with his adoration of Greek (when a thing pleased him greatly he was wont to talk of it as “Greek Verse”), his delight in journeys and sight-seeing, his dislike for literary talk save with intimates and equals, his vanities and vengeances, his pride in the memory of favours bestowed on him by popes and princes, his “infinita maraviglia” over Virgil's versification and metaphor, his fondness for masculine rhymes and blank verse, his quiet Christianity, is a figure deserving perhaps of more study than is likely to be bestowed on that “new world” of art which it was his glory to fancy his own, by discovery and by conquest.

The best editions of Chiabrera are those of Rome (1718, 3 vols. 8vo); of Venice (1731, 4 vols. 8vo); of Leghorn (1781, 5 vols. 12mo); and of Milan (1890, 3 vols. 8vo). Only contain his lyric work; all the rest he has written has been long forgotten.

CHIANA (anc. Clanis), a river of Tusculum, which rises in the Apennines S. of Arezzo, runs through the valley of Chiusi, and after receiving the Paglia just below Orvieto, falls into the Tiber after a course of 60 m. In Roman times its waters ran entirely into the Tiber. It often caused considerable floods in the valley of Clusium (Chiusi) which were noticeable even in Rome itself, and in A.D. 15 it was proposed to divert part of its waters into the Arnus, a project which was abandoned owing to the opposition of the Florentines (TAC. ANN. I. 76, 79). In the middle ages the whole of its valley from Arezzo to Chiusi was an uninhabitable swamp; but at the end of the 18th century the engineer Count Fossombroni took the matter in hand, and moved the watershed some 25 m. farther south, so that its waters now flow partly into the Arno and partly into the Tiber.

CHIAPAS, a Pacific coast state of southern Mexico on the Guatemalan frontier, bounded by the states of Tabasco on the N. and Vera Cruz and Oaxaca on the W. Pop. (1895) 318,730; (1900) 360,799, a large proportion of which are Indians; and, (1895) 3,844, 802, only contain his lyric work; all the rest he has written has been long forgotten.

CHIAPAS, a Pacific coast state of southern Mexico on the Guatemalan frontier, is calculated to improve the industrial and social conditions of the people. The principal industries are agriculture, which is very backward, stock-raising, timber-cutting, fruit-farming and salt-making. Coffee-planting is a new industry on the Pacific slope of the Sierra Madre at elevations of 2000 to 4000 ft., and has met with considerable success. Rubber plantations have also been laid out, principally by American companies, the Castilla elástica doing well. The exports include cattle, hides, coffee, rubber, fruit and salt. The mineral resources include gold, silver, copper and petroleum, but no mines were in operation in 1906. The capital, Tuxtla Gutierrez (pop. 9395 in 1900), is on the plateau, 33 m. from the Rio Sabinas, and 138 m. N.E. of the Pacific port of Tonalá. The former capital, San Cristobal (pop. about 5000 in 1890), about 40 m. E. of Tuxtla, is an interesting old town and the seat of the bishopric of Chiapas, founded in 1525 and made famous through its associations with Las Casas. Tapachula (pop. in 1895, 6775), the capital of the department of Soconusco, 18 m. from the Guatemalan frontier, is a rising commercial town of the new coffee district. It is 24 m. inland from the small port of San Benito, is 559 ft. above sea-level, and has a healthy climate. Other prominent towns with their populations in 1895, are Comitan, or Comitan (9310), on the Rio Grijalva about 40 m. S.E. of San Cristobal, and chiefly distinguished for its fine church and convent dedicated to San Domingo; Pichucalco.

water

10.5 ft. above the lake, but the level was greatly raised—in some places more than 10 ft.—over a large area, between 1855 and 1860. The West Side, especially in the north-west near Humboldt Park, is much higher (75 ft.). A narrow inlet from the lake, the Chicago river, runs W. from its shore about a mile, dividing then into a north and a south branch, which run respectively to the N.W. and the S.W., thus cutting the city into three divisions known as the North, the West and the South "Sides," which are united by three car-tunnels beneath the river as well as by the bridges across it. The river no longer empties into Lake Michigan since the completion of the drainage canal. Its commercial importance is very great: indeed it is probably the most important non-tidal stream of its length in the world, or if it be regarded as a harbour, one of the greatest; the tonnage of its yearly commerce far exceeds that of the Suez Canal and almost equals the tonnage of the foreign trade (the domestic excluded) of the Thames at London. The increase in size of the new freighters that ply on the Great Lakes has proved one serious difficulty, and the bridges and the river tunnels, which hinder the deeper cutting of the channel, are others. The improvement of the outer harbour by the national government was begun in 1833. Great breakwaters protect the river mouth from the silting shore currents of the lake and afford secure shelter in an outer roadstead from its storms, and there is a smaller inner-basin (about 450 acres, 16 ft. depth) as well. But the river itself which has about 15 m. of navigable channel, in part lined with docks, is the most important part of the harbour. Its channel has been repeatedly deepened, and is maintained—especially since 1896, after its control as a navigable stream passed (1890) to the federal government—widened and straightened by the removal of jutting building constructions along its shores. Grain elevators of enormous size, coal yards, lumber yards and grimy warehouses or factories crowd close upon it. The shipping facilities on the river are not so good in some ways as those in the Great Lakes, and the demand is seasonal. Several old mosques remain. The town was famous for its muslins, but the industry is now decayed. The roadstead and lighthouse of Calilingapatam are about 16 m. to the north, and the East Coast railway has a station 8 m. inland.

CHICAGO

a city, a port of entry and the county-seat of Cook county, Illinois, U.S.A., the second city of the United States in population, commerce and manufactures; pop. (1900) 1,698,575; and (1910) 2,185,283. It is situated at the south-west corner of Lake Michigan (lat. 41° 56', long. 87° 38' W.), about 913 m. distant by railway from New York, 912 m. from New Orleans, 2265 m. from Los Angeles, and 2330 m. from Seattle. The climate is very changeable and is much affected by the lake; changes of more than thirty degrees in temperature within 24 hours are not at all rare, and changes of twenty degrees are common. The city is the greatest railway centre of the United States, and was for several decades practically the only commercial outlet of the great agricultural region of the northern Missis-

sippi Valley. Trunk lines reach E. to Montreal, Boston, New York, Philadelphia, Baltimore (the nearest point on the Atlantic coast, 855 m.), S. to Charleston, Savannah, Mobile, New Orleans, Port Arthur and Galveston; W. to the Pacific at Los Angeles, San Francisco, Seattle and Vancouver, and to most of these by a variety of routes. In 1905 about 14% of the world’s railway mileage centred in Chicago.

With its suburbs Chicago stretches along the shore of Lake Michigan about 40 m. (the city proper 26.5), and the city in 1910 had a total area of 191.4 sq. m. 1 It spreads loosely and irregularly backward from the lake over a shallow alluvial basin, which is rimmed to the W. by a low moraine-water-parting 2 that separates the drainage of the lake from that of the Mississippi Valley. The city site has been built up out of the "Lake Chicago" of glacial times, which exceeded in size Lake Michigan. Three lakes—Calumet, 3172 acres; Hyde; and part of Wolf—with a water-surface of some 4100 acres, lie within the municipal limits. The original elevation of what is now the business heart of the city was only about 7 ft. above the lake, but the level was greatly raised—in some places more than 10 ft.—over a large area, between 1855 and 1860. The West Side, especially in the north-west near Humboldt Park, is much higher (75 ft.). A narrow inlet from the lake, the Chicago river, runs W. from its shore about a mile, dividing then into a north and a south branch, which run respectively to the N.W. and the S.W., thus cutting the city into three divisions known as the North, the West and the South "Sides," which are united by three car-tunnels beneath the river as well as by the bridges across it. 3 The river no longer empties into Lake Michigan since the completion of the drainage canal. Its commercial importance is very great: indeed it is probably the most important non-tidal stream of its length in the world, or if it be regarded as a harbour, one of the greatest; the tonnage of its yearly commerce far exceeds that of the Suez Canal and almost equals the tonnage of the foreign trade (the domestic excluded) of the Thames at London. The increase in size of the new freighters that ply on the Great Lakes has proved one serious difficulty, and the bridges and the river tunnels, which hinder the deeper cutting of the channel, are others. The improvement of the outer harbour by the national government was begun in 1833. Great breakwaters protect the river mouth from the silting shore currents of the lake and afford secure shelter in an outer roadstead from its storms, and there is a smaller inner-basin (about 450 acres, 16 ft. depth) as well. But the river itself which has about 15 m. of navigable channel, in part lined with docks, is the most important part of the harbour. Its channel has been repeatedly deepened, and in recent years—especially since 1896, after its control as a navigable stream passed (1890) to the federal government—widened and straightened by the removal of jutting building constructions along its shores. Grain elevators of enormous size, coal yards, lumber yards and grimy warehouses or factories crowd close upon it. The shipping facilities on the river are not so good in some ways as those in the Great Lakes, and the demand is seasonal. Several old mosques remain. The town was famous for its muslins, but the industry is now decayed. The roadstead and lighthouse of Calilingapatam are about 16 m. to the north, and the East Coast railway has a station 8 m. inland.

CHICAGO

a city, a port of entry and the county-seat of Cook county, Illinois, U.S.A., the second city of the United States in population, commerce and manufactures; pop. (1900) 1,698,575; and (1910) 2,185,283. It is situated at the south-west corner of Lake Michigan (lat. 41° 56', long. 87° 38' W.), about 913 m. distant by railway from New York, 912 m. from New Orleans, 2265 m. from Los Angeles, and 2330 m. from Seattle. The climate is very changeable and is much affected by the lake; changes of more than thirty degrees in temperature within 24 hours are not at all rare, and changes of twenty degrees are common. The city is the greatest railway centre of the United States, and was for several decades practically the only commercial outlet of the great agricultural region of the northern Missis-

1 In 1889 the total area (land and water) was increased from 438 to 1699 sq. m.; in 1890 the land area was 1634 sq. m.

2 About 15 ft. in elevation; hence the possibility of the drainage canal.

3 Among the last are many swing and "jack-knife" bridges, bascules, and a lift-bridge that can be lifted bodily 155 ft. above the channel. Steam, compressed air and electricity are used as power. By 1900 almost all were being built of a length exceeding 400 ft.
public buildings are crowded within an area of about 1-5 sq. m. The congestion of the streets—considerably lessened since the freeways have relieved the amount of heavy traffic—is proportionately great, and their din and crush is characteristic of the city. The residential districts, on the other hand, are unevenly and loosely spread; many areas well within the city are only sparsely settled. A belt of “bad lands” occupied by factories, shanties, etc.—partially surrounds the best business district. The smoke resulting from the use of soft coal has given a drab and dingy colour-tone to the buildings. The low and even relief of the site and the long vistas of the streets do not lend themselves to the picturesque; yet this quality may be claimed for the high and broken skyline, varied colour, massiveness, bustle and impressive commercialism of the business district. Chicago is generally credited with being the original home of the steel-frame “sky-scaper,” though there are now many more buildings elsewhere in America. The unstable soil of sand, clay and boulders that underlies the city is unfavourable to tall constructions, and necessitates extraordinary attention to foundations. The bed-rock lies, on an average, 50 ft. below the level of the lake (in places more than a hundred). To the rock the foundations are often sunk in great masses of concrete and steel. In other cases great arches, made of the same materials, are resting or “floating” upon the clay, and sustain and distribute the weight of the building. The Auditorium (1889; cost, $3,500,000), a huge building containing a hotel and a theatre (5000 seats), is one of the most massive commercial structures of the country. The Masonic Temple (cost, $3,000,000) is the tallest in the city (302 ft.). In 1909 there were some 475 structures ten or more storeys high. Not a few are noteworthy, for size—as the Monadnock office building of 16 storeys, with some 6600 occupants, and the new Northwestern Railway station; or for the luxury of their interior fittings—as the La Salle, Blackstone and Sherman hotels; or for boldness and originality in the treatment of the steel-frame type; or for association with the city’s life—as the Fine Arts building, given over to varied purposes of public amusement and artistic or intellectual improvement, or the Railway Exchange (cased in tile), the University Club, the Chamber of Commerce and the Board of Trade; and many others are handsome and dignified. The Marquette building is adorned with very ornate and handsomely decorated with works of art, is one of the finest office-buildings in the country. There are a number of enormous retail stores. The largest, and one of the finest in the world, is that of Marshall Field. The wholesale establishment of the same firm is the work of H. H. Richardson, considered one of his best, and one of the most admirable examples among American commercial buildings. The city hall and county court house (cost, $4,500,000) is an enormous double building in a free French Renaissance style, with colonnaded façades. The new Federal building (finished in 1905; cost, $4,750,000) is a massive edifice (a low rectangle surrounded by a higher inner cross and crowned with a dome). The public library (1893–1897, $2,125,000), constructed of dark granite and limestone, with rich interior decorations of varied frescoes, mosaics, ornamental bronze and iron work, and mottos, is one of the handsomest libraries of the country. The Chicago Art Institute (1892–1893; Italian Renaissance), the Chicago Orchestral building (1901), and the Commercial National Bank, are also noteworthy. The finest residence streets are the Lake Shore Drive, the North Side and the “South Side” boulevards that connect the parks of the city—of which Michigan Avenue, Drexel and Grand are the finest. The city's environs are not of particular beauty, but there are bluffs on the lake to the north, and woods to the south-west, and a fair variety of pretty hill and plain; and though the Calumet and Chicago rivers have been given over to commerce, the valley of the Desplains will be preserved in the park system. On the South Side the Union Stockyards, established in 1865, by far the largest in the world. They cover about 500 acres, have about 45 m. of feeding and watering troughs, and can accommodate at one time more than 400,000 hogs, cattle, sheep and horses.

Public Works and Communications.—Local transit is provided for by the suburban service of the steam railways, elevated electric roads, and a system of electric surface cars. Two great public works demand notice: the water system and the drainage canal. Water is pumped from Lake Michigan through several tunnels connecting with “cribs” located from 2 to 5 m. from shore. The “cribs” are heavy structures of timber and iron loaded with stone and enclosing the in-take cylinders, which join with the tunnels well below the bottom of the lake. The first tunnel was completed in 1867. The capacity of the tunnel was estimated in 1868 by two competent authorities at 180,000,000 gallons daily. The average daily supply in 1909 was 475,000,000 gallons; there were then 16 m. of tunnels below the lake. The wastes of the city—street washings, building sewage, the offal of slaughter-houses, and wastes of distilleries and rendering houses—were originally turned into the lake, but before 1870 it was discovered that the range of impurity extended already a mile into the lake, half-way to the water “crib,” and it became evident that the lake could not be indefinitely contaminated. The Illinois and Michigan Canal, for which the right of way was granted in 1819 and which was built in 1836-1841 and 1843-1848, and opened in 1848 (cost, $6,557,681), was once thought to have solved the difficulty; it is connected with the main (southern) branch of the Chicago river, 5 m. from its mouth, with the Illinois river at La Salle, the head of steam navigation on the Illinois river, and is the natural successor in the evolution of transportation of the old Chicago portage, 1 m. in length, between the Chicago river and the headwaters of the Kankakee; it was deepened as to draw water out from the lake, whose waters thus flowed toward the Gulf of Mexico; it was long, 40-42 ft. wide, and 4-7 ft. deep, but proved inadequate for the disposal of sewage. A solution of the problem was imperative by 1876, but almost all the wastes of the city continued nevertheless to be poured into the lake. In 1890 a sanitary district, including part of the city and certain suburban areas to be affected, was organized, and preparations made for building a greater canal that should do effectively the work it was once thought the old canal could do. The new drainage canal, one of the greatest sanitary works of the world, constructed between 1892 and 1900 under the control of the trustees of the Sanitary District of Chicago (cost up to 1901, $35,448,921), joins the south branch of the Chicago with the Desplains river, and so with the Illinois and Mississippi, and is 28-5 m. long, of which 15 m. were cut through rock; it is 22 ft. deep and has a minimum width of 164 ft. The canal, or sewer, is flushed with water from Lake Michigan, and its waters are pure within a flow of 150 m. Its capacity, which was not at first fully utilized, is 500,000 cu. ft. per minute, sufficient entirely to renew the water of the Chicago river daily. A system of settling sewers to withdraw drainage into the lake was begun in 1898; and the construction of a canal to drain the Calumet region was begun in 1910. The Illinois and Michigan canal is used by small craft, and the new drainage canal may also be used for shipping in view of the Federal government's improvements of the rivers connecting it with the Mississippi for the construction of a ship-canal for large vessels. The canal also made possible the development (begun in 1903) of enormous

---

1 The highest value ever paid in Chicago for land actually sold, up to 1905, was $250 per sq. ft. (1892); a few rental contracts have been based upon an assumed higher value. A municipal ordinance placing the extreme construction at 150 ft. was repealed in 1902.

2 This is true of all the new large buildings. The old post office, completed in 1895 at a cost of $5,375,000, was practically a crumbling ruin within fifteen years; its foundations were inadequate. Years were spent in sinking the foundation of the new Federal building that replaced the old.

3 Total excavation, 47,337,904 cubic yds. of solid rock, 12,265,000.

4 It has been conclusively proved that the Illinois is purer than the Mississippi at their junction. The undiluted sewage of the old canal drove the fish from the river, but they have come back since the opening of the new canal.
hydraulic power for the use of the city. The Illinois and Michigan Canal has been supplemented by the Illinois and Mississippi Canal, commonly known as "the Hennepin," from its starting at the great bend of the Illinois river 10 m. above Hennepin, not far below La Salle; the first appropriation for it was made in 1890, and work was begun in 1892 and completed in October 1901. Its course from Hennepin is by the Bureau Creek valley to the mouth of Queen river on the Rock river, thence by the Rock river and a canal around its rapids at Milan to its mouth at Rock Island on the Mississippi river. This barge canal is 80 ft. wide at water-line, 52 ft. wide at the bottom, and 7 ft. deep. Its main feeder is the Rock river, dammed by a dam nearly 1500 ft. long between Sterling and Rock Falls, Illinois, where the opening of the canal was celebrated on the 24th of October 1907.

Beginning with 1892 steam railways began the elevation (or depression) of their main tracks, of which there were in 1904 some 838 mi. within the city. Another great improvement was begun in 1901 by a private telephone company. This is an elaborate system of freight subways, more than 65 mi. of which, underlaying the entire business district, had been constructed before 1900. It is the only subway system in the world that clear the streets by the lessening of trucking, in place of devoting itself to the transportation of passengers. Direct connexion is made with the freight stations of all railways and the basements of important business buildings, and coal, building materials, ashes and garbage, railway luggage, heavy mail and other kinds of heavy freight are expeditiously removed and delivered. Telegraph and telephone wires are carried through the tunnel, and can be readily repaired. The subway was opened for partial operation in 1905.

Parks.—The park system may be said to have been begun in 1869, and in 1870 aggregated 185 acres. Chicago then acquired the name of "The Garden City," which still clings to her. But many other cities have later passed her (until in 1904, though the second largest of the country, she ranked only thirty-second in her holdings of park area per capita among American cities of 100,000 population). In 1908 the acreage of the municipal parks was 3179 acres, and there were 61.4 m. of boulevards. After 1900 another period of ambitious development began. The improvement of old and the creation of new "internal" parks, i.e. within the cordon of those older parks and boulevards that once girdled the city but have been surrounded in its later growth; the creation of a huge metropolitan ring—similar to that of Boston but vaster (35,000 acres)—of lake bluffs, hills, meadows, forests and river valley; and a great increase of "neighbourhood parks" in the poor districts, are included in the new undertakings. The neighbourhood park, usually located near a school, is almost all-inclusive in its provision for all comers, from babyhood to maturity, and is open all day. There are sand gardens and wading ponds and swings and day nurseries, gymnasiums, athletic fields, swimming pools and baths, reading-rooms—generally with branches of the city library— lunch counters, civic club rooms, frequent music, assembly halls for theatricals, lectures, concerts, or meetings, penny savings banks, and in the winter skating ponds. These social centres have practically all been created since about 1895. There are also municipal baths on the lake front and elsewhere. The larger parks include several of great size and beauty. Lincoln Park (area 552 acres), on the lake shore of the North Side, has been much enlarged by an addition reclaimed from the lake. It has fine monuments, conservatories, the only zoological garden in the city, and the collections of the Academy of Sciences. A breakwater carriage drive connects with a Boulevard to Fort Sheridan (27 m.) up the lake. Jackson Park (542 acres), on the lake shore of the South Side, was the main site of the World's

1 The cut was almost entirely through firm clay. It was estimated (1905) that the total freight handled weekly in the business district was nearly 500,000 tons, and the subway was designed to handle this amount when completed. The tunnels are 12-5×14 and 7-5×6 ft., all concrete. The cars are drawn by trolley wire locomotives on a track of 2 ft. gauge.

Columbian Exposition of 1891, and contains the Field Columbian Museum, occupying the art building of the exposition. It is joined with Washington Park (371 acres) by the Midway Plaisance, a wide boulevard, which tends to be converted into a magnificent sunken water-course connecting the lagoons of the two parks with Lake Michigan. Along the Midway are the grey-stone buildings of the University of Chicago, and of its (Blaine) School of Education. On the West Side are three fine parks—Douglas, Garfield (with a fine conservatory), and Humboldt, which has a remarkable rose garden (respectively 182, 187 and 206 acres), and in the extreme South Side several others, including Calumet (66 acres), by the lake side, and Marquette (322 acres). Jackson Boulevard, Western Avenue Boulevard and Marshall Boulevard join the South and the West Park systems. Neither New York nor Boston has preserved as has Chicago the beauty of its water front. The shore of the North Side is quite free, and beginning a short distance above the river is skirted for almost 30 m. by the Lake Shore Drive, Lincoln Park and the Sheridan Drive. The shore of the South Side is occupied by railway tracks, but they have been sunk and the shore considerably improved. In addition to Calumet and Jackson parks there is the Midway Plaisance, and there is Grant Park, which has since been included in Grant Park, mostly reclaimed from the water. Here are the public library and the building of the Art Institute (opened in 1893); the park had also been proposed as the site of a new building for the Field Museum of Natural History. The park and boulevards along the lake in 1905 stretched 10-78 m., within the city limits, or almost half the total frontage. The inner "boulevards" are broad park ways, 150 to 300 ft. wide, joining the parks; Chicago was the first American city to adopt this system.

Art.—Among the monuments erected in public places are a Columbus by D. C. French and a bronze replica of French's equestrian statue of Washington in Paris; statues of John A. Logan and Abraham Lincoln by St Gaudens; monuments commemorating the Haymarket riot and the Fort Dearborn massacres; statues of General Grant, Stephen A. Douglas, La Salle, Schiller, Humboldt, Beethoven and Linnaeus. There is also a memorial to G. B. Armstrong (1822-1871), a citizen of Chicago, who founded the railway mail service of the United States. A city art commission approves all works of art before they become the property of the city, and at the request of the mayor acts in various ways for the city's aesthetic betterment. The Architectural Club labours for the same end. A Municipal Art League (organized in 1899) has done good work in arousing civic pride; it has undertaken, among other things, campaigns against bill-board advertisements, and against the smoke nuisance.

The Art Institute of Chicago contains valuable collections of paintings, reproductions of bronzes and sculpture, architectural casts, and other objects of art. Connected with it is the largest and most comprehensive art school of the county—including newspaper illustration and a normal school for the training of teachers of drawing in the public schools. The institute was incorporated in 1879, though its beginnings go back to 1850, while the school dates from 1878. The courses in architecture are given with the co-operation of the Armour Institute of Technology. There are also a number of notable private art collections in the city. In 1894 the Chicago Public School Art Society was founded to secure the placing of good works of art in the public schools. Picture collections are also exchanged among the neighbourhood-park homes.

Music in Chicago owes much to the German element of the population. Especially noteworthy among musical organizations were 50 m. of them in 1904.
are the Apollo Musical Club (1872) and The Theodore Thomas Orchestra, which has disputed with the Boston Orchestra the claim to artistic primacy in the United States. Its leader from its organization in 1881 until his death in 1905 was Theodore Thomas, who had long been identified with summer orchestral concerts in the city. In 1904 a fund was gathered by public subscription to erect a handsome building and endow the orchestra.

The Field Museum of Natural History, established (1894) largely by Marshall Field, is mainly devoted to anthropology and natural history. The nucleus of its great collection was formed by various exhibits of the Columbian Exposition which were presented to it. Its collections of American ethnology, of exceptional richness and value, are constantly augmented by research expeditions. In addition to an original endowment of $1,000,000, Mr. Field bequeathed to the museum $8,000,000, to be utilized in part for the new building which is being erected in Jackson Park.

Libraries.—At the head of the libraries of the city stands the public library (established 1872; opened 1874), supported by taxation, which on the 1st of June 1910 had 402,848 volumes and held 195,000 circulated 1,856,012 volumes. In 1889 John Crerar (1855-1889), a wealthy munificent judge endowed a non-circulating fund in the year 1910, which was estimated to amount to $3,000,000. The library was incorporated in 1894 and was opened in 1897; in February 1908 it had 216,000 volumes and 60,000 pamphlets. It occupies a floor in the Marshall Field Building on Wabash Avenue. Another reference library was established (opened in 1887) by a bequest of Walter L. Newberry. It has a rich endowment, and in February 1908 had 191,644 volumes and 43,644 pamphlets. By a plan of co-operation each of these three libraries devotes itself primarily to special fields: the John Crerar is best for the natural, physical and social sciences; the Newberry particularly strong in history, music, medicine, rare books and fine editions; the public library covers the whole range of general literature. The library of the University of Chicago contained in 1908 some 450,000 titles. Among other collections are those of the Chicago Historical Society (1856; about 150,000 titles in 1908), the Athenaeum (1871); the Law Institute and Library (1857), which in 1897 had 3,560,000 volumes; the Art Institute, the Field Museum of Natural History, the Academy of Sciences (1857) and the libraries of various schools.

Universities and Colleges.—There are three universities situated wholly or in part in the city. The leading institution is the University of Chicago (see CHICAGO, UNIVERSITY OF). The professional department of North-Western University is in Chicago, while its academic department is in the suburb of Evanston. North-Western University was organized in 1851 and is under Methodist Episcopal control. Its students in 1908 (exclusive of pupils in "co-operating" theological schools) numbered 3,890; the best equipped departments are those of dentistry, medicine and pharmacy. There are two Roman Catholic colleges in Chicago: Loyola University (chartered in 1879), with a department of law, called Lincoln College (1908), and a medical department; and St. Stanislaus College (1879). The College of Physicians and Surgeons is the medical department of the University of Illinois, at Champaign-Urbana. Theological schools independent of the universities include the McCormick Theological Seminary (Presbyterian), the Chicago Theological Seminary (Congregational, opened 1858, and including German, Danish, Norwegian and Swedish Institutes); the Western Episcopal Theological Seminary; a German Lutheran theological seminary, and an Evangelical Lutheran theological seminary. There are a number of independent medical schools and schools of dentistry and veterinary surgery. The Lewis Institute (bequest 1877, opened 1896), designed to give a practical education to boys and girls at a nominal cost, and the Armour Institute of Technology, one of the best technical schools of the country, provide technical education and are well endowed. The Armour Institute was founded in 1892 by Philip D. Armour, and is a non-profit educational institution. It comprises the College of Engineering, including, besides the usual departments, a department of chemical engineering and a department of fire protection engineering, a department of "commercial tests," and the Armour Scientific Academy (preparatory). In 1907 the Institute had 869 students. The Chicago Academy of Science (1857) has a handsome building and museum collections in Lincoln Park. The leading daily newspapers are the Record-Herald, Evening Post, News (evening) and Journal (evening), all Independent; the Inter-Ocean and Tribune, Republican; and the Evening American and Examiner, both Democratic. There are several journals in German, Bohemian, Polish, Swedish, Norwegian and Danish. Many trade papers are published in the city, which is also a centre for much of the religious publishing of the Middle West. Chicago's position in the labour world has made it the home of several socialist and anarchistic periodicals.

Industry and Commerce.—Chicago's situation at the head of the most south-western of the Great Lakes has given it great importance in trade and industry. The development of its railway facilities as a recognition of its supreme advantages as the easiest interchange of Middle and Western states, on whose wealth its prosperity is founded. The growth of its trade has been marvellous. The last years of the 19th century showed, however, an inevitable loss to Chicago in the growth of Duluth, Kansas City and other rivals in strategic situations. In particular, the struggle of the North and South railways in the Mississippi Valley to divert to ports on the Gulf of Mexico grain and other freight caused great losses to Chicago. An enormous increase in the cereal trade of Philadelphia, Baltimore, Newport News and Norfolk was partly due to the traffic eastward over lines S. of Chicago. The traffic of the routes through Duluth and Canada does not, indeed, represent in the main actual losses, for the traffic is largely a new growth; but there has been nevertheless a considerable drain to these routes from American territory once tributary to Chicago. Altogether the competition of the Gulf roads and the lines running S.W. from Duluth had largely excluded Chicago by 1890 (acc. to board of trade) from the grain trade of the Missouri river, and in conjunction with southerly E. and W. routes had made serious inroads upon traffic S. of that river. Its facilities of receiving and distributing remain nevertheless unequalled, and it still furnishes the centre of the traffic between the northern Atlantic seaboard and the West.

New York alone, among American cities, has a greater trade. Chicago is the greatest railway centre, the greatest grain market, the greatest live-stock market and meat-packing centre, and the greatest lumber market of the world. The clearings of her associated banks amounted to $13,781,843,612 in the year 1909. The wholesale trade was estimated in 1875 at $193,000,000 and in 1905 at $1,781,000,000. The average annual grain receipts (including flour in wheat equivalent) in the years 1900-1904 amounted to 265,000,000 bu. (1,290,319 in 1854; 72,360,104 in 1875), and the shipments to 1,009,825,668 bu. The first shipment of wheat was of 78 bu. in 1838. The grain elevators are among the sights of Chicago. They are enormous storehouses into which the grain is elevated from ships and cars, sorted into grades and reloaded for shipment; all the work is done by machinery. Their capacity, in 1904, was 65,140,000 bu.² In the same quinquennial period 1900-1904 the average yearly receipts of flour aggregated 1,807,066,000 lb., and of shingles, 416,711,000; of flour, 305,87,734; of lard, 8,334,904; of sheep, 3,333,231; of butter, 239,698,911 lb.; of hides, 167,442,077 lb.; of dressed beef, 1,126,095,490 lb.; of

1 Thomas Hughes was a leader in gathering English gifts for such a library immediately after the "great fire." A nucleus of 10,000 volumes—7,000 from England and 3,000 from other countries, especially Germany—was thus secured.

² In 1900-1904 the average freight per bushel of wheat to New York was $0.04998 by the all-water; $0.10554 by the all-rail route. In 1859 it cost $0.1757 to send a bushel of corn to Buffalo from Chicago; in 1890, $0.019.
lard, 410,688,819 lb; of pork, 191,371 bbl; of other hog products, 600,503,504 lb. The combined tonnage in and out averaged 14,135,460 tons.¹ There is a large direct trade with Europe, mainly in goods that come in bond by rail from Atlantic ports. In 1907 the value of Chicago's imports was $27,058,662, and of its exports, $5,643,302.

The value of manufactures (from establishments under the "factory system") in 1900 was $797,879,414, 71-2% of all those of Illinois, and in 1905 was $505,056,277, 67-7% of all those of the state; in both these years Chicago was second only to New York City. Wholesale slaughtering and meat-packing (not including many by-products), valued at $36,577,049 (32-2% of the city's total) in 1900 and at $260,581,486 (28-2% of the total) in 1905, are the most important of the city's industries; in 1905 the product value in Chicago was 29-3% of that for the slaughtering and meat-packing of the entire United States. Other important manufactures are foundry and machine shop products, $44,501,571 in 1900, and $51,774,695 in 1905; and other iron and steel products, $35,058,700 in 1900 and $27,074,307 in 1905; clothing ($28,093,572 in 1900, and $40,013,481 in 1905); cars and other railway construction, $38,496,956 in 1900 and $36,403,310 in 1905; malt liquors ($12,950,865 in 1900, and $16,083,421 in 1905), and furniture ($12,444,512 in 1900 and $17,488,257 in 1905). The Illinois Steel Company has the largest rolling mills in the world. The McCormick Harvesting Machine Company is the largest concern in the world manufacturing agricultural implements. Pullman in southern Chicago, in the sparsely settled outskirts of the city, is a model little "labor town," planned and constructed with regard for both appearances and conveniences by the Pullman Palace Car Company, which has its works here. The town consists mainly of workmen's cottages. Most of the population are dependent upon the work cars. The Pullman Company owns and operates dining and sleeping cars on practically all the railways of the country. In its own cars it builds on the cars not only passenger and freight cars on contract.

Meat-packing is the greatest local industry and is that for which Chicago is best known. In the enormous stock-yards from two-thirds to four-fifths of the cattle and hogs received are killed, and sent out in various forms of prepared meats and by-products (lard, fertilizers, glue, butterine, soap, candles, etc.).² This industry is remarkable for the extraordinary division of labor in its processes. In the preparation of a bullock more than thirty specialties are involved, and some twenty different rates of pay. This system enabled the packing companies, until checked by the development of labor unions, to save money not only by paying low wages for crude labor and high for skilled, but to develop wonderful expertness in every line, and so "speed up" the workmen to a remarkable pace.³ No more interesting field can be found for the study of the qualities of foreign races. The introduction of the refrigeration railroad car in the seventies of the 19th century, making possible the distant marketing of frozen meats, enormously increased the business. The workmen of the yards were organized in a national union of meat packers in 1897, and all the different classes of workmen have their separate organizations, formed mainly between 1900 and 1902. The number of women employed more than doubled in the decade 1891-1900, constituting probably about 5% of the total in the latter year.

Administration.—Chicago is governed under a general city-charter law of Illinois of 1870, accepted by the city in 1875. In November 1904 the people of Illinois adopted a constitutional amendment authorizing the legislature of the state to provide a complete new system of local government for Chicago, but the old system continued and is here described, the new charter, from which so much had been hoped, being rejected by the voters of the city by an overwhelming majority in September 1907. A common council chosen by wards and renewed in half each year controls the budget, police, liquor licences, city contracts and the granting of franchises; it also confirms appointments made by the mayor and by a vote of two-thirds may pass legislation over his veto. The mayor, chosen for four years, is the executive head of the city, and has large power of appointment and removal, limited by a civil service law, under which he must submit reasons for removals, while two-thirds of the council may prevent them. On the other hand the mayor can veto separate items in the council's budget. The administrative departments are generally headed by single commissioners; but those of elections, education and the public library are exceptions. The council was once all important, but as early as the charter of 1851 it began to lose power to the mayor, whose influence increased, gaining first in the financial department. Administration was once performed entirely by boards, as in other American cities: every specific problem or demand for municipal activity was met by an appeal to the state legislature for special legislation and the creation of a board. The substitution of single commissioners began in 1876. The state constitution of 1870 forbade special legislation, prescribed a general city charter law and forbade special amendatory acts for Chicago. This stopped grave abuses, but because a large part of the state has not been interested in Chicago's special needs and demands for betterment it also saddled upon the city an organization which in 1907 remained practically the same as in 1870, when Chicago was an overgrown town of 300,000 inhabitants. Chicago was the only large city of the state, and a charter generalized from village experience was unsuitable for it. The parts of Cook county outside the city have also been very jealous of forwarding its interests by legislation. In 1848 the city was incorporated as a town, ¹² the complete absorption of the county or at least the reconstitution of the county government,⁴ which the constitution left unchanged, and which, with the city's growth, has caused clash of interests and authority. Nor is this dual government—though the city has above nine-tenths of the population and pays nine-tenths of the taxes of the county—the only anomaly. Illinois has had since 1848 a modified New England "township" local-government system, and various townships have been absorbed by Chicago, yet they all retained till after 1900 their political structure and some of their functions. There are three park commissions, two appointed by the governor and one by circuit court judges, created for different parts of the old city, differently constituted and all independent of the city; their jurisdiction was not enlarged as the city grew, so large portions remained free of charges for parks and boulevards. A special park commission now supersedes them and lessens this anomaly, though increasing administrative diversity. A sanitary and drainage district, not larger than the city area but quite different from it, was created in 1886 (present form 1890) to carry through the drainage canal. The school board has been nominally separate from and almost independent of the city government in power since 1857. The courts of law are courts of the city of Illinois, but a certain number of justices of the peace are designated by the mayor to act as police magistrates. The initiative and referendum in local matters has been made possible under a state law, and has been several times exercised in important questions. Financial arrangements have been loose and inefficient. Independent taxing power has been lavishly granted. State, county, city, three park boards, the school board, the public library board, the drainage board, and as late as 1903 ten townships,⁶ exercised this sovereign right within the municipal area. Tax assessment ²⁴ Cook county is Republican in politics generally, the rural districts being so strong as to overbalance the normal Democratic plurality in Chicago. Thus another ground of jealousy is found in the distribution of county offices.

"An amendment of 1903 provided that the legislature should enact the consolidation of the townships with the city in matters of taxation, but no further steps had been taken to the end of 1907."
valuations have been excessively irregular (e.g., the "equalized" value for 1875 was $55,000,000 greater than that for 1874), and apparently very low. The average assessment value for the years (1904 to 1906 was $3,438,720,879 (402-28 millions in 1904, and 477-19 millions in 1906), and in 1907 the highest taxing rate was 8%. The bonded debt in 1908 was $23,157,600, about half of it old ($11,367,726 in 1876). 4:5 millions contracted to aid the World's Fair of 1893. In the early years following 1900 the city paid more than half of its income on police; this expenditure, per capita of population, was not high (in 1901 Boston $5-03, New York $3-21, Chicago $2-10), and the results were not exactly efficient. The difficulty is that the city is poor and can pay only for strict necessities. Its poverty is due mainly to state laws. The taxation limit on property is 1% on the cash value, thus compelling special dependence upon all sorts of indirect taxes; the debt limit is 5% on the assessed valuation. Since 1900 relief has been given by state law in some matters, such as for the park system. The water system has been operated by the city since 1851, and has been financially very successful from the beginning; rates are far lower than in the other great cities of the country, and a handsome net revenue accrues to the treasury. And in 1879 the total income (including the police) was paid for, gradually out of the general tax levy and was not built by the sale of bonds, gave excellent results in the city service. The city, like the state, has power to regulate the price of gas sold by private companies. The elevation of the railway tracks within the city was begun in 1892; at the close of 1908 the railway companies had accepted ordinances of the City Council for the elevation of 90-77 m. of main tracks and 584-91 m. of all tracks, and the construction of 724 subways, at an estimated cost of $65,000,000; at that time the railway companies had completed the elevation of 133-83 m. of main tracks and 776 m. of all tracks, and had constructed 367 subways, at a total expense of $52,500,000. The system of intercepting sewers begun in 1898 to complete the service of the drainage canal has been constructed with the profits of the water system.

In addition to the movement for a new charter to remove the anomalies and ease the difficulties already referred to, two great problems have been in the forefront in recent years: the lessening of municipal corruption and the control of local transit agencies.

The traction question may be said to have begun in 1865; in which year, and again in 1883, public opinion was bitterly aroused against an attempt of the traction companies to secure a ninety-nine year extension of franchises. Following 1883 all lines were consolidated and enormously over-capitalized (in 1905 about $85,000,000 of stocks and bonds on a 6% basis, two-thirds of which rested on the franchise). In 1893-1897 the companies attempted to assure a 50-year extension of franchises were defeated by Governor John P. Altgeld (1847-1902), by the formation of a Municipal Voters' League, and by a representative committee of 1,000 from Chicago to attend the legislature at Springfield. The transit service of the city had for years been antiquated and inadequate. At the mayor's elections in 1897, 1899, 1901 and 1903 the victory lay with the opponents of the companies, and in 1903 the successful party stood for immediate municipal acquisition of all roads. Meanwhile, under the state referendum act, the city in 1905 voted overwhelmingly for municipal ownership and operation (142,838 to 27,500); the legislature in 1903 by the Mueller law gave the city the requisite powers; the people accepted the law, again declared for municipal ownership, and for temporary compulsion of adequate service, and against granting any franchise to any company, by four additional votes similarly conclusive. At last, after tedious negotiations, a definite agreement was reached in 1906 assuring an early acquisition of all roads by the city. The issue of bonds for municipal railways was, however, declared unconstitutional that year; and at the municipal elections of 1907 there was a complete reversal of policy; a large majority voted this time against municipal ownership in favour of leaving the working of the street railways in private hands, and strengthening the powers of municipal control.

The active campaign for the improvement of municipal service and politics may be said to have begun in 1896. A civil service system was inaugurated in 1895. The salaries of the councilmen were raised with good effect. Numerous reform associations were started to arouse public opinion, such as the Citizens' Association of Chicago, organized in 1874, the Civic Federation (1894), the Municipal Voters' League (1896), the Legislative Voters' League (1901), the Municipal Lecture Association (1900), the Referendum League of Illinois (1901), the Civil Service Reform Association of Chicago, the Civil Service Reform Association of Illinois (1902), the Merchants' Club, the City Club (1903), the Law and Order League (1904), Social of Social Hygiene (1906), and many of the women's clubs took an active part. They stood for the real enforcement of the laws, sanitation, pure food, public health, the improvement of the schools and the widening of their social influence, and (here especially the women's clubs) aesthetic, social and moral progress. The Merchants' Club reformed the city's book-keeping, and secured the establishment (1890) of the first state pawnbrokers' society. The Civic Federation demonstrated (1896) that it could clean the central streets for 3c per hour while the city was paying (the city has since saved the difference); it urged the movement for school and other educational and social services. The Municipal Voters' League investigated and published the records of candidates for the city council, and recommended their election or defeat as the case may be. Moreover, a "Municipal Museum" was organized in 1905, mainly supported by private aid, but in part by the board of education, in order to collect and make educational use of materials illustrating municipal administration and conditions, physical and social.

Education and Charity. The school board is appointed by the mayor. Since 1904 a merit system has been applied in the advancement of teachers; civil service rules cover the rest of the employees. Kindergartens were maintained without legal sanction in connexion with the public schools for several years, and for more than twenty-five years as private schools, before their legal establishment as a part of the system in 1899. Free evening schools, very practical in their courses, are utilized mainly by foreigners. Vacation schools were begun in 1896. So far as possible the school buildings are kept open for school, lectures and entertainments, serving thus as wholesome social centres; and a more adequate use is made of the large investment (in 1908 about $44,500,000) which they represent. In all the public schools manual training, household arts and economy, and commercial studies are a regular part of the curriculum. A department of scientific pedagogy and child study (1900) seeks to secure a development of the school system in harmony with the results of scientific study of children (the combination of hand and brain training, the use of audio-visual methods, an elastic curriculum during the adolescent period, &c.). The expenditure for all purposes by the city in 1903 for every dollar expended for schools was only $1.71; a ratio paralleled in only a few cities of the country.

Hospitals, infirmaries, dispensaries, asylums, shelters and homes for the defective, destitute, orphaned, aged, erring, friendless and incurably diseased; various relief societies, and organizations that sift the good from the bad among the mendicant, the economically inefficient, and the virtual pauper, represent the charity work of the city. Among public institutions are the Cook County hospital (situated in the "Medical District" of the West Side, where various hospitals and schools are gathered near together), asylum and poor house. Since 1883 a Lincoln Park Sanitarium has been maintained for infants and small children during warm weather. Two legal aid societies, the Chicago Bureau of Justice (1888) and the Protective Agency for Women and Children, collect small wage claims and otherwise aid the poor or helpless. The most important charitable societies of the city are the United Charities of Chicago (1900), the United Hebrew Charities (1857), and the Associated Jewish Charities (1900). The first is the union of the Relief and Aid Society (1857) and the Bureau of Charities (1894),

\[\text{The net revenue per million gallons in 1890-1899 was } \$35.04.\]
and tries to prevent overlapping of efforts and to weed out fraud.

Following the gradual development of New York state laws on behalf of children was enacted the Illinois Juvenile Court Law, which came into force on the 1st of July 1890 and was largely the result of Chicago's interest in juvenile reform. Much philanthropic work centres in the West Side with its heterogeneous population. A famous institution is Hull House, a social settlement of women, which aims to be a social, charitable, and educational neighbourhood centre. It was established in 1889 by Miss Jane Addams, who became the head-worker, and Miss Ellen Gates Starr. It includes an art building, a free kindergartten, a fine gymnasia, a crèche, and a diet kitchen; and supports classes, lectures and concerts. It has had a very great influence throughout the United States. The Armour mission (1886) for the poor is organized with similar breadth of scope.

Population.—Of the total population in 1900 not less than 34.6% were foreign-born; the number of persons either born abroad, or born in the United States of foreign parentage (i.e., father or both parents foreign), was 77.4% of the population, and in the total number of males of voting age the foreign-born predominated (53.4%). Of the latter category 68.2% were already citizens by naturalization. 3.9% of the inhabitants of ten years of age or upward were illiterate (unable to write), while the percentage of foreign-born whites was 8.9% (93.9% of illiterate males were of voting age). Germans, Irish, Poles, and Bohemians made up respectively 20.1, 12.6, 8.6, 8.3 and 6.2% of the foreign-born population. It was estimated in 1903 by a very competent authority that above 500,000 persons spoke German, 125,000 Polish, 100,000 Swedish, 90,000 Bohemian, 50,000 Norwegian, 50,000 Yiddish, 35,000 Dutch, 25,000 Italian, 20,000 Danish, 17,000 French and 12,000 Irish (Celtic), and that each of fourteen foreign languages was spoken by more than 10,000 people: "Newspapers appear regularly in 10 languages, and church-services may be heard in about 20 languages. Chicago is the second largest Bohemian city of the world, the third Swedish, the fourth Norwegian, the fifth Polish, the fifth German (New York being the fourth). In all there are some 40 languages spoken by . . . over one million" persons.1 The death-rate of Chicago is the lowest of the great cities of the country. Births are but slightly in excess of deaths, so that the growth of the city is almost wholly from immigration. The death-rate is the lowest of the great cities of the country (16.2 in 1900; New York, 20.4; Boston, 20.1, &c.).

The growth of Chicago has been remarkable even for American cities. Any resident of four-score years living in 1830 has seen it grow from a settlement of fourteen houses, a frontier military post among the Indians, to a great metropolis, fifth in size among the cities of the world. In 1838 what is now the business centre was fenced in as a pasture; in 1831 the Chicago mail was deposited in a dry-goods box; the tax-levy of 1834 was $48,90, and a well that constituted the city water-works was sunk at a cost of $95,50; in 1843 hogs were barried from the town streets. Such facts impress upon one, as nothing else can, the marvellously rapid growth of the city. In 1830 with a population of less than 100, in 1840 with 4479, the increase by percentages in succeeding decades was as follows: 507-3, 264-6, 173-6, 68-3, 118-6 and 54.4; an increase equivalent to 8.6% annually, compounded. Such a continuous "boom" no other American city has ever known.

History.—The river Chicago (an Indian name of uncertain meaning, but possibly from Ojibwa she-kagong, "wild onion place") was visited by Jollet and Marquette in 1673, and later by La Salle and others. It became a portage route of some importance, used by the French in passing to the lower Illinois country. In 1804 the United States established here Fort Dearborn. In 1812, during the Indian War of Tecumseh, the garrison and settlers, who had abandoned the fort and were retreating toward safety, were attacked and overpowered by the savages at a point now well within the city. The fort was re-established and fitfully occupied until its final abandonment in 1837. When Cook county was organized in 1831, Chicago, then a tiny village, became the seat of justice. It became a town in 1833 and a city in 1837. By that time Chicago was confident of its future. The federal government had begun the improvement of the harbour, and the state had started the Illinois and Michigan canal. There was a federal land-office also, and the land speculator and town promoter had opened a chapter of history more picturesque, albeit sordid, than in any of the old French days. The giant growth of the lake trade had drawn attention before railway connexion was secure with the East in 1852, making progress even more rapid thereafter. During the Civil War a large prison-camp for Confederate prisoners, Camp Douglas, was maintained at Chicago. In 1870 the city had 306,605 inhabitants and was already a commercial centre of immense importance.

In 1871 it suffered a terrible calamity. On the 8th of October a fire broke out near the lumber district on the West Side. Two-thirds of the city's buildings were wood, and the summer had been excessively dry, while to make conditions worse a high and veering wind fanned the flames. The conflagration leaped the river to the South and finally to the North Side, burned over an area of 3½ sq. m., destroyed 17,430 buildings and property valued at $196,000,000,2 and rendered almost 100,000 people homeless; 290 lost their lives. The flames actually licked the shore in 5½ hours. Thousands of persons, fleeing before the flames and fire-brands, sought refuge on the shore and even in the waters of the lake. Robbery, pilage, extortion, orgies and crime added to the general horror. In the South Side the fire was checked on the 9th by the use of gunpowder; in the North (where the water-workes were early destroyed) it had extended almost to the prairie when rainfall finally ended its ravages, after about twenty-seven hours of destruction. With the exception of the San Francisco fire of 1906 this was the greatest fire of modern times. A vast system of relief was organized and received generous aid from all parts of the world. The money contributions from the United States and abroad were $4,906,782; of this foreign countries contributed nearly $1,000,000 (England half of this). These funds, which were over and above gifts of food, clothing and supplies, were made to last till the close of 1876. Out of them temporary homes were provided for nearly 40,000 people; barracks and better houses were erected, workmen were supplied with tools, and women with sewing-machines; the sick were cared for and the dead buried; and the poorer classes of Chicago were probably never so comfortable as during the first two or three years after the fire. The rebuilding of the city was accomplished with wonderful rapidity. Work was begun before the cinders were cold. The business district was largely rebuilt within a year, and within three there were hardly scars of the calamity. Wood was barried from a large area (and subsequently from the entire city), and a new Chicago of brick and stone, larger, finer and wealthier, had taken the place of the old. Business and population showed no set-back in their progress. The solidity and permanence of this prosperity were confirmed during the financial panic of 1875, when Chicago banks alone, among those of the large cities of the country, continued steadily to pay out current funds.

In its later history certain special factors stand out, apart from continued commercial progress.

Chicago has been a storm centre of labour troubles, some of them of a specially spectacular character. There were great strikes in the packing industry in 1886, 1894 and 1904. But more noteworthy are the railway strike of 1894 and the unsuccessful teamsters' strike of 1905. The former began in the works of the Pullman Car Company, and its leader was Eugene Victor Debs (b. 1855). When the contentions of the Pullman employees were taken up by the American Railway Union the strike immediately extended to tremendous proportions. Union men

1 There was an insurance of $88,034,122 on the losses, of which about a half was recovered. F. L. Olmsted estimated that one-third of the roof surface and one-half the cubic contents of the city's buildings were destroyed.

2 Prof. C. D. Buck in Decennial Publications of the University of Chicago (1903, vol. 6).
CHICAGO, UNIVERSITY OF

125

throughout the country refused to handle Pullman cars, and since Pullman cars are almost invariably attached to mail trains the transportation of the United States mail was thus obstructed. Chicago, as the greatest railway centre of the country and the home of the strike, was naturally the seat of the most serious complications. There was much rioting and destruction of property, and the railway service was completely disorganized. President Cleveland, on the ground of preventing obstruction of the mail service, and of protecting other federal interests, ordered a small number of federal troops to Chicago. Those interests were, he contended, menaced by "domestic violence" evidently beyond the control of the state power. Governor Altgeld denied the inability of the state to deal with the difficulty, and entered a strong protest against Federal interference, but he himself did nothing to put down the disorder. Federal troops entered the state, and almost immediately the strike collapsed. The high officials of the Railway Union, for ignoring a court injunction restraining them from interfering with the movement of the mails, were imprisoned for long terms for contempt of court.

Out of a strike in the McCormick works in 1886 there sprang another famous incident in Chicago's history. The "inter

To the University of Chicago, had been organized in "groups" about two years earlier, and were very active. They were advocating a "general strike" for an eight-hour day, and the tense excitement among the laborers of the city, owing to the McCormick strike, induced unusually ultra uterances. There was a riot at the McCormick works on the 3rd of May, in which several men were killed by the police. An anarchist meeting was called for the next day at the Haymarket, a square in Randolph Street, and when the authorities judged that the speeches were too revolutionary to be allowed to continue, the police undertook to disperse the meeting. A bomb was thrown, and many policemen were injured, seven fatally. No person could be proved to have thrown the bomb, or to have been directly implicated in its throwing; but on the ground that they were morally conspirators and accomplices in the killing, because they had repeatedly and publicly advocated such acts against the servants of government, seven anarchists were condemned to death. An application to the United States Supreme Court for a writ of error was unanimously denied.

The four-hundredth anniversary of the discovery of America was commemorated by a World's Columbian Exposition held at Chicago. The site was in Jackson Park and the adjoining Midway, and included 686 acres, of which 188 were covered by buildings. On the 21st of October 1892—corresponding to the 12th of October 1492, o.s.—the grounds were formally dedicated, and on the following 1st of May opened to the public, continuing open for six months. The number of paid admissions was 21,500,000; of total admissions 27,539,521. The buildings, planned by a commission of architects—among whom John W. Root and Daniel H. Burnham of Chicago were responsible for the general scheme—formed a collection of remarkable beauty, to which the grounds, planned by F. L. Olmsted, intersected by lagoons and bordered by the lake, lent an appropriate setting. The entire cost of the fair is variously estimated at from 33 to 43 million dollars, according to the inclusiveness of the estimate; the local cost may be put at $28,151,169. Of this Chicago gave about 103 millions, in addition to a preparatory house-clearing that cost 32 millions; and finally a very small dividend was paid to stockholders. The whole undertaking, carried through with remarkable enterprise, was an artistic and educational triumph of the first order.

Owing to its position Chicago has long been a favourite con-

1 Four were hanged, 1 committed suicide, 2 had their death sentence commuted to life-imprisonment, the eighth was sentenced to imprisonment for 15 years. 981 men were paralled in selecting the jury. Governor J. P. Altgeld in 1893 pardoned the three in prison on the ground that the jury was "packed" and consequently incompetent, that no evidence connected the prisoners with the crime, and that the presiding judge was prejudiced. See an article by Judge J. E. Gary, who presided at the trial, in the Century Magazine (April 1893).

1 A small Baptist college of the same name—established in 1855 on land given by S. A. Douglas—went out of existence in 1886.

1 If, however, the total is reckoned on the basis of nine months of residence the figure for 1907-1908 would be 3202.

2 The Divinity School has a graduate department and three under graduate departments, doing work in English, in Danish and Norwegian, and in Swedish. Allied with the Divinity School of the University is the "Disciples' Divinity House" (1894), a theological school of the Disciples of Christ.
Administration link the university closely with practical life. In extension work the university has been active from the beginning, instructing not only by lectures but by correspondence (a novel and unique feature among American universities); in the decade 1802–1902, 1715 persons were prepared by the latter method for matriculation in the university (11.0% of the total number of matriculants in the decade). Extension lectures were given in twenty-two states. At Chicago the work of the university is continuous throughout the year: the "summer quarter" is not as in other American schools a supplement to the teaching year, but an integral part; and it attracts the teachers of the middle western states and of the south. In the work of the first two years, known together as the Junior College, men and women are in the main given separate instruction; but in the Senior College years unrestricted co-education prevails. Students are mainly controlled by self-government in small groups ("the house system"). Relations with "affiliated" (private) colleges and academies and "cooperating" (public) high-schools also present interesting features. The value of the property of the university in 1908 was about $25,578,000. The value of buildings in 1908 was $4,406,191, and of productive funds $14,186,235. Upon the death of President Harper, Harry Pratt Judson (b. 1849), then head professor of political science and dean of the faculties of arts, became acting president, and on the 20th of January 1907 he was elected president.

See the Decennial Publications of the University (since 1903), especially vol. i. for details of history and administration.

**CHICANE—CHICHELEY**

**CHICANE**. The pettifogging subterfuge and delay of sharp law-practitioners, also any deliberate attempt to gain unfair advantage by petty tricks. A more common English form of the word is "chicanery." "Chicane" is technically used also as a term in the game of bridge for the points a player may score if he holds no trumps. The word is French, derived either from chauvin, Persian for the stick used in the game of "polo," still played on foot and called chicane in Languedoc (the military use of chicane, to take advantage of slight variations in ground, suits this derivation), or from chic, meaning little or petty, from the Spanish chico, small, which appears in the phrase "a chic a chic" ("less than little").

**CHICHELEY, HENRY** (1364–1443). English archbishop, founder of All Souls College, Oxford, was born at Higham Ferrers, Northamptonshire, in 1363 or 1364. Chicheley told the pope in 1443, in asking leave to retire from the archbishopric, that he was in his eightieth year. He was the third and youngest son of Thomas Chicheley, who appears in 1368 in still extant town records of Higham Ferrers as a suitor in the mayor's court, and in 1381–1382, and again in 1384–1385, was mayor: in fact, for a dozen years he and Henry Barton, school master of Higham Ferrers grammar school, and one Richard Brabazon, filled the mayoralty in turns. His occupation does not appear; but his eldest son, William, is on the earliest extant list (1373) of the Grocers' Company, London. On the 9th of June 1405 Chicheley was admitted, in succession to his father, to a bursary in Higham Ferrers. His mother, Agnes Pincheon, is said to have been of gentle birth. There is therefore no foundation in fact for the silly story (copied into the Dict. Nat. Bioi. from a local historian, J. Cole, Wellingborough, 1838) that Henry Chicheley was picked up by William of Wykeham when he was a poor ploughboy to eat his scanty meal off his mother's lap, whatever that means. The story was unknown to Arthur Duck, fellow of All Souls, who wrote Chicheley's life in 1617. It is only the usual attempt, as in the cases of Whittington, Wolsey and Gresham, to exaggerate the rise of a successful man. The first recorded appearance of Henry Chicheley himself is at New College, Oxford, as Chicheley, eighth among the undergraduate fellows, in July 1387, in the earliest extant hall-book, which contains weekly lists of those dining in Hall. It is clear from Chicheley's position in the list, with eleven fellows and eight scholars, or probationer-fellows, below him, that this entry does not mark his first appearance in the college, which had been going on since 1373 at least, and was chartered in 1379. He must have come from Winchester College in one of the earliest batches of scholars from that college, the sole feeder of New College, not from St John Baptist College, Winchester, as guessed by Dr William Hunt in the Dict. Nat. Bioi. (and repeated in Mr Grant Robertson's History of All Souls College) to cover the mistaken supposition that St Mary's College was not founded till 1395. St Mary's College was in fact founded the same year, and no one from that college appears in any lists since 1373 (A. F. Leach, History of Winchester College), while no such college as St John's College at Winchester ever existed.

Chicheley appears in the Hall-books of New College up to the year 1392/93, when he was a B.A. and was absent for ten weeks from the 6th of December to the 6th of March, presumably for the purpose of his ordination as a sub-deacon, which was performed by the bishop of Derry, acting as suffragan to the bishop of London. He was then already benefited, receiving a royal ratification of his estate as parson of Llanvarchell in the diocese of St Asaph on the 20th of March 1391/92 (Cal. Pat. Rolls). In the Hall-book, marked 1393/94, but really for 1394/95, Chicheley's name does not appear. He had then left Oxford and gone up to London to practise as an advocate in the principal ecclesiastical court, the court of arches. His rise was rapid. Already on the 8th of February 1395/96 he was, on a commission with several knights and clerks to hear an appeal in a case of John Meldon, Esquire v. John Shawe, citizen of London, from Sir John Cheyne, kt., sitting for the constable of England in a county court. He was called to the bar in 1393, and was in the rolls of the day, he was paid with ecclesiastical prebends. On the 11th of April 1396 he obtained ratification of the parsonage of St Stephen's, Wallbrook, presented on the 30th of March by the abbot of Colchester, no doubt through his brother Robert, who restored the church and increased its endowment. In 1397 he was made archdeacon of Dorset by Richard Milford, bishop of Salisbury, but litigation was still going on about it in the papal court till the 27th of June 1399, when the pope extinguished the suit, imposing perpetual silence on Nicholas Bubwith, master of the rolls, his opponent. In the first year of Henry IV. Chicheley was parson of Sherston, Wiltshire, and prebendary of Nantgwyn in the college of Abercwyll, North Wales; on the 23rd of February 1401/2, now called doctor of laws, he was pardoned for bringing in, and allowed to use, a bull of the pope "providing" him to the chancellorship of Salisbury cathedral, and canons in the nunns' churches of Shaftesbury and Willton in that county, and on the 7th of January 1402/3 he was archdeacon of Salisbury. This year his brother Robert was senior sheriff of London. On the 7th of May 1404, Pope Boniface IX. provided him to a prebend at Lincoln, notwithstanding he already held prebends at Salisbury, Lichfield, St Martin's-le-Grand and Abergwyll, and the living of Brington. On the 5th of January 1405 he found time to attend a court at Higham Ferrers and be admitted to a bursary there. In July 1405 Chicheley began a diplomatic career by a mission to the new Roman pope Innocent VII., who was professing his desire to end the schism in the papacy by resignation, if his French rival at Avignon would do likewise. Next year, on the 5th of October 1406, he was sent with Sir John Cheyne to Paris to arrange a lasting peace and the marriage of Prince Henry with the French princess Marie, which was frustrated by her becoming a nun at Poissy next year.
In 1406 renewed efforts were made to stop the schism, and Chicheley was one of the envoys sent to the new pope Gregory XII. Here he utilized his opportunities. On the 31st of August 1407 Guy Mone (he is always so spelt and not Mohun, and was probably from one of the Hampshire Meons; there was a John Mone of Havant admitted a Winchester scholar in 1397), bishop of St David’s, died, and on the 12th of October 1407 Chicheley was by the pope provided to the bishopric of St David’s. Another bull the same day gave him the right to hold all his benefices with the bishopric.

At Siena in July 1408 he and Sir John Cheyne, as English envoys, were received by Gregory XII with special honour, and Bishop Repindgon of Lincoln, ex-Wychcliffe, was one of the new batch of cardinals created on the 18th of September 1408, most of Gregory’s cardinals having deserted him. These, together with Benedict’s revoluting cardinals, summoned a general council at Pisa. In November 1408 Chicheley was back at Westminster, when Henry IV received the cardinal archbishop of Bordeaux and determined to support the cardinals at Pisa against both popes. In January 1409 Chicheley was named with Bishop Hallam of Salisbury and the prior of Canterbury to represent the Southern Convocation at the council, which opened on the 25th of March 1409, arriving on the 24th of April. Obedience was withdrawn from both the existing popes, and on the 6th of June a new pope elected in their stead. Chicheley and the other envoys were received on their return as saviours of the world; though the result was summed up by a contemporary as trichism instead of schism, and the Church as giving three husbands instead of two. Chicheley now became the subject of a leading case, the court of king’s bench deciding, after arguments reheard in three successive terms, that he could not hold his previous benefices with the bishopric, and that, spite of the maxim Papa potest omnia, a papal bull could not supersede the law of the land (Year-book ii. H. iv. 37, 59, 79). Accordingly he had to resign livings and canonicities wholesale (April 28, 1410). As, however, he had obtained a bull (August 20, 1409) enabling him to appoint his successors to the vacant preferments, including his nephew William, though still an undergraduate and not in orders, to the chancellorship of Salisbury, and a prebend at Lichfield, he did not go empty away. In May 1410 he went again on an embassy to France; on the 11th of September 1411 he headed a mission to discuss Henry V’s marriage with a daughter of the duke of Burgundy; and he was again there in November. In the interval Chicheley found time to visit his diocese for the first time, and be enthroned as bishop of St David’s on the 11th of May 1411. He was with the English force under the earl of Arundel which accompanied the duke of Burgundy to Paris in October 1411 and there defeated the Armagnacs, an exploit which revealed to England the weakness of the French. On the 30th of November 1411 Chicheley, with two other bishops and three earls and the prince of Wales, knelt to the king to receive public thanks for their administration. That he was in high favour with Henry V. is shown by his being sent with the earl of Warwick to France in July 1413 to conclude peace. Immediately after the death of archbishop Arundel he was nominated by the king to the archbishopric, elected on the 4th of March, translated by papal bull on the 28th of April, and received the pall without going to Rome for it on the 24th of July.

These dates are important as they help to save Chicheley from the charge, versified by Shakespeare (Henry V. act i. sc. 2) from Hall’s Chronicle, of having tempted Henry V. into the conquest of France for the sake of diverting parliament from the demands of the Church. There is no contemporary authority for the charge, which seems to appear first in Redman’s rhetorical history of Henry V., written in 1540 with an eye to the political situation at that time. As a matter of fact, the parliament at Leicester, in which the speeches were supposed to have been made, began on the 30th of April 1414 before Chicheley was archbishop. The rolls of parliament show that he was not present in the parliament at all. Moreover parliament was so far from pressing disendowment that on the petition of the Commons it passed a savage act against the heresies “commonly called Lollardy,” which “aimed at the destruction of the king and all temporal estates,” making Lollards felons and ordering every justice of the peace to hunt down their schools, conventicles, congregations and confederates.

In his capacity of archbishop, Chicheley remained what he had always been chiefly, the lawyer and diplomatist. He was present at the siege of Rouen, and the king committed to him personally the negotiations for the surrender of the city in January 1419 and for the marriage of Katherine. He crowned Katherine at Westminster (20th February 1421), and on the 6th of December baptised her child Henry VI. He was of course a persecutor of heretics. No one could have attained or kept the position of archbishop at the time without being so. So he presided at the trial of John Claydon, Skinner and citizen of London, who after five years’ imprisonment at various times had made public abjuration before the late archbishop, Arundel, but now was found in possession of a book in English called The Lantern of Light, which contained the heinous heresy that the principal cause of the persecution of Christians was the illegal retention by priests of the goods of this world, and that archbishops and bishops were the special seats of antichrist. As a relapsed heretic, he was “left to the secular arm” by Chicheley. On the 1st of July 1413 Chicheley directed a letter to the bull of Innocent IX, which had been written against him. On the 12th of February 1420 proceedings were begun before him against William Taylor, priest, who had been for fourteen years excommunicated for heresy, and was now degraded and burnt for saying that prayers ought not to be addressed to saints, but only to God. A striking contrast was exhibited in October 1424, when a Stamford friar, John Russell, who had preached that any religious poïet concumbere cum muliere and not mortally sin, was sentenced only to retract his doctrine. Further persecutions of a whole batch of Lollards took place in 1428. The records of convocation in Chicheley’s time are a curious mixture of persecutions for heresy, which largely consisted in attacks on clerical endowments, with negotiations with the ministers of the crown for the object of cutting down to the lowest level the clerical contributions to the public revenues in respect of their endowments. Chicheley was tenacious of the privileges of his see, and this involved him in a constant struggle with Henry Beaufort, bishop of Winchester. In 1421, while Henry V. was alive, he successfully protested against Beaufort’s being made a cardinal and legate a latere to supersede the legitimate succession of Canterbury; and on the submission of Henry V. after the death of Hainault, Beaufort was successful, and in 1426 became cardinal and legate. This brought Chicheley into collision with Martin V. The struggle between them has been represented as one of a patriotic archbishop resisting the encroachments of the papacy on the Church of England. In point of fact it was almost wholly personal, and was rather an incident in the rivalry between the duke of Gloucester and his half-brother, Cardinal Beaufort, than one involving any principle. Chicheley, by appointing a jubilee to be held at Canterbury in 1420, “after the manner of the Jubilee ordained by the Popes,” threatened to divert the profits from pilgrims from Rome to Canterbury. A ferocious letter from the pope to the papal nuncios, on the 19th of March 1423, denounced the proceeding as calculated “to enrage mere souls and extort from them a profane reward, thereby setting up themselves against the apostolic see and the Roman pontiff, to whom alone so great a faculty has been granted by God” (Cap. Pap. Reg. vii. 12). Chicheley also incurred the papal wrath by opposing the system of papal provision which diverted patronage from English to Italian hands, but the immediate object was to prevent the introduction of the bulls making Beaufort a cardinal. Chicheley had been careful enough to obtain “Papal provisions” for himself, his pluralities, his bishopric and archbishopric.

But, after all, it is not as archbishop or statesman, persecutor, papalist or antipapalist that Chicheley is remembered, but for his educational foundations. He endowed a hutch, i.e. chest or loan-fund for poor scholars at New College, and another for the
The king's secretary, like Chicheley himself, a scholar of Win-chester and fellow of New College, was named as first warden. A papal bull for the college was obtained on the 21st of June 1439; and further patents for endowments from the 11th of May 1441 to the 28th of January 1443, when a general confirmation charter was obtained, for which £1000 (£5000 at least of our money) was paid. It is commonly represented that the endowment was wholly derived from alien priories bought by Chicheley from the crown. In truth, not so large a proportion of the endowment of All Souls was derived from this source as was that of New College. The only alien priories granted were Abberbury in Oxonshire, Wedon Pinkney in Northampton-shire, Romney in Kent, and St Clare and Llangenith in Wales, all very small affairs, single manors and rectories, and these did not form a quarter of the whole endowment. The rest, particularly the manor of Edgware, which made the fortune of the college, was bought from private owners. Early in 1443 the college was opened by Chicheley with four bishops in state. The statutes, not drawn up until the 2nd of April 1443, raised the number of the college to forty. Like the college buildings, they were based on an exact copy of those of New College, mutatis mutandis. The college is sometimes described as being different from other colleges in being merely a large chantry to pray for the souls of the dead warriors. But it was no more a chantry than the other colleges, all of which, like the monasteries and collegiate churches, were to pray for their founders' and other specified souls. Indeed, All Souls was more of a lay foundation than its model. For while at New College only twenty out of seventy fellows were to study law instead of arts, philosophy and theology, at All Souls College sixteen were to be "jurists," and only twenty-four "artists"; and while at New College there were ten chaplains and three clerks necessarily, at All Souls the number was not defined but left optional; so that there are now only one chaplain and four bible clerks. Ten days after he sealed the statutes, on the 15th of April 1443, Chicheley died and was buried in Cantebury cathedral on the north side of the choir, under a fine effigy of himself erected in his lifetime. There is what looks like an excellent contemporary portrait in one of the windows of All Souls College, which is figured in the Victoria County History for Hampshire, ii. 262.  

CHICHESTER-OF-BELFAST, ARTHUR CHICHESTER, BARTON (1563—1625), lord-deputy of Ireland, second son of Sir John Chichester of Raleigh, Devonshire, by Gertrude, daughter of Sir William Courtenay of Powderham, was born at Raleigh in May 1563, and was educated at Exeter College, Oxford. He commanded a ship against the Spanish Armada in 1588, and is said to have served under Drake in his expedition of 1595. Having seen further service abroad, he was sent to Ireland at the end of 1598, and was appointed by the earl of Essex to the government of Carrickfergus. When Essex returned to England, Chichester rendered valuable service under Mountjoy in the war against the rebellious earl of Tyrone, and in 1601 Mountjoy recommended him to Cecil in terms of the highest praise as the fittest person to be entrusted with the government of Ulster. On the 15th of October 1604 Chichester was appointed lord-deputy of Ireland. He announced his policy in a proclamation wherein he abolished the semi-feudal rights of the native Irish chieftains, substituting for them fixed dues, while their tenants were to become dependent "wholly and immediately upon his
CHICHESTER

129

majesty." Tyrone and other Irish chieftains presented this summary interference with their ancient social organization, and their resistance was strengthened by the ill-advised measures against the Roman Catholics which Chichester was compelled to take by the orders of the English ministers. He himself was moderate and enlightened in his views on this matter, and it was through his influence that the harshness of the anti-Catholic policy was relaxed in 1607. Meantime his difficulties with the Irish tribal leaders remained unsolved. But in 1607, by "the flight of the Earls" (see O'NEIL), he was relieved of the presence of the two formidable Ulster chieftains, the earls of Tyrone and Tyrconnell. Chichester's policy for dealing with the situation thus created was to divide the lands of the fugitive earls among Irishmen of standing and character; but the plantation of Ulster as actually carried out was much less favourable and just to the native population than the lord-deputy desired. In 1613 Chichester was raised to the peerage as Baron Chichester of Belfast, and in the following year he went to England to give an account of the state of Ireland. On his return to Ireland he again attempted to moderate the persecuting policy against the Irish Catholics which he was instructed to carry out; and although he was to some extent successful, it was probably owing to his opposition to this policy that he was recalled in November 1614. The king, however, told him "You may rest assured that you do leave that place with our very good grace and acceptance of your services"; and he was given the post of lord-treasury of Ireland. After living in retirement for some years, Chichester was employed abroad in 1622; in the following year he became a member of the privy council. He died on the 10th of February 1625 and was buried at Carrickfergus.

Lord Chichester married Lettice, daughter of Sir John Perrot and widow of Walter Vaughan of Golden Grove. He had no children, and his title became extinct at his death. The heir to his estates was his brother Sir Edward Chichester (d. 1648), governor of Carrickfergus, who in 1625 was created Baron Chichester of Belfast and Viscount Chichester of Carrickfergus. This nobleman's eldest son Arthur (1606-1675), who distinguished himself as Colonel Chichester in the suppression of the rebellion of 1641, was created earl of Donegall in 1647, and was succeeded in his titles by his nephew, whose great-grandson, Arthur, 5th Earl of Donegall, was created Baron Fisherton in the peerage of Great Britain (the other family titles being in the peerage of Ireland) in 1709, and Earl of Belfast and marquess of Donegall in the peerage of Ireland in 1701. The present marquess of Donegall is his descendant.

CHICHESTER, a city and municipal borough in the Chichester parliamentary division of Sussex, England, 60 m. S.S.W. from London by the London, Brighton & South Coast Railway. Pop. (1901) 12,224. It lies in a plain at the foot of a spur of the South Downs, a mile from the head of Chichester Harbour, an inlet of the English Channel. The principal church of the Holy Trinity, a vaulted building, is dedicated to the close of the 11th century, and has recently been restored. For the see had been removed to Chichester from Selsey in 1075. The first church was consecrated in 1108, but fires in 1114 and 1187 caused building to continue steadily until the close of the 13th century. Bishop Ralph Luffa (1001-1113) was the first great builder, and was followed by Seffrid II. (1118-1204). Norman work appears in the nave (arcade and triforium), choir (arcade) and elsewhere; but there is much very beautiful Early English work, the choir above the arcade and the eastern part being especially fine. The nave is remarkable in having double aisles on each side, the outer pair being of the 13th century. The church is also unique among English cathedrals in the possession of a detached campanile, a massive and beautiful Perpendicular structure with the top storey octagonal. The principal modern restorations are the upper part of the north-west tower, which copies the Early English work of that on the south-west; and the fine central tower and spire, which had been erected at different periods in the 14th century, but collapsed, doing little damage to the fabric, in 1861. Under the direction of Sir Gilbert Scott and others they were reconstructed with scrupulous care in preserving the original plan. The Lady chapel at the east end is in the main early Decorated, but greatly restored; the library is a fine late Norman vaulted room; the cloisters are Perpendicular and well restored; and the bishop's palace retains an Early English chapel. The cathedral is 303 ft. long within, 131 ft. across the transepts, and 90 ft. across the nave with its double aisles. The height of the spire is 277 ft.

At the junction of the four main streets of the town stands the market cross, an exquisite octagonal structure in ornament Perpendicular style, built by Bishop Story, c. 1500, perhaps the finest of its kind in the United Kingdom. The hospital of St Mary was founded in the 12th century, but the existing buildings are in a style transitional from Early English to Decorated. Its use as an almshouse is maintained. Other ancient buildings are the churches of St Olave, in the construction of which Roman materials were used; and of St Andrew, where is the tomb of William Collins, whose memorial with others by the sculptor Flaxman is in the cathedral; the Guildhall, formerly a Great Men's chapter house; the buildings of Carfax and of the Gate leading into the cathedral close; and the Vicars College. The city retains a great part of its ancient walls, which have a circuit of about a mile and a half, and, at least in part, follow the line of Roman fortifications. The principal modern buildings, besides churches and chapels, are the council house, corn exchange, market house, and museum of the Chichester Literary Society. The grammar school was founded in 1497 by Bishop Story. There is a large cattle market, and the town has a considerable agricultural trade, with breweries and tanneries. A canal connects with Chichester Harbour. The diocese includes the whole county of Sussex except a few parishes, with very small portions of Kent and Surrey. The municipal borough is under a mayor, six aldermen and eighteen councillors. Area, 1538 acres.

The Romano-British town on this site was perhaps Regina or Regni. Many inscriptions, pottery, coins, &c., have been found, and part of the medieval walls contain a Roman cave. An interesting inscription from this site is preserved at Goodwood. Situated on one Roman road in direct connexion with London and another leading from east to west, Chichester (Cicesterc, Cicestra) remained of considerable importance under the South Saxon kings. In 697 King Edgar established a mint here. Though Domesday Book speaks of one hundred and forty-two burgages in Chichester and a charter of Henry I. mentions the borough, the earliest extant charter is that granted by Stephen, confirming to the burgesses their customs and rights of the borough and gild merchant as they had them in the time of his grandfather. This was confirmed by Henry II. Under Henry III. the fee farm rent was £38: 10s., but this was reduced by a charter of t. Edward II. to £36, the customs of wool, hides and skins being reserved to the king. Edward III. directed that the Sussex county court should be held at Chichester, and this charter, the common grantees of the previous charters were also granted by Edward III., Richard II., Henry VI., Edward IV., and Henry VII., who gave the mayor and citizens cognizance of all kinds of pleas of assize touching lands and hereditaments of freehold tenure. A court leet, court of record and bailiffs' court of liberties still exist. The charters were also confirmed by Henry VIII., Edward VI., Philip and Mary, and Elizabeth. In 1604 the city was incorporated under a mayor and aldermen. Since 1295, when it first returned a member, Chichester has been regularly represented in parliament. Throughout the middle ages Chichester was a place of great commercial importance, Edward III. establishing a wool staple hcre in 1348. Fairs were granted by Henry I. and Henry VII. Fuller mentions the Wednesday market as being famous for corn, while Camden speaks of that on Saturday as the greatest for fish in the county. The markets and a fair on the 20th of October are still held.

See Victoria County History, Sussex; Alexander Hay, History of Chichester (Chichester, 1804).
CHICKAMAUGA CREEK, a small tributary of the Tennessee river, which it joins near Chattanooga, Tennessee, U.S.A. It gives its name to the great battle of Chickamauga in the American Civil War, fought on the 19th of September 1863, between the Federal army of the Cumberland under Major-General W. S. Rosecrans and the Confederate army under General Braxton Bragg. For the general operations of Rosecrans' army in 1863 see AMERICAN CIVIL WAR. A successful war of manœuvre had brought the army of the Cumberland from Murfreesboro to Decherd, Tenn., and Bragg's army lay on the Tennessee at and above Chattanooga. Rosecrans was expected by the enemy to manœuvre so as to gain touch with the Union forces in the upper Tennessee valley, but he formed an entirely different plan of operations. One part of the army demonstrated in front of Chattanooga, and the main body secretly crossed the river about Stevenson and Bridgeport (September 4th). The country was mountainous, the roads few and poor, and the Federals had to take full supplies of food, forage and ammunition with them, but Rosecrans was an able commander, his troops were in good hands, and he accepted the risks involved. These were intensified by the want of good maps, and, in the event, at one moment the army was placed in a position of great danger. A corps under A. McD. McCook moved south-eastward across the ridges to Alpine, another under Thomas marched via Trenton on McMllon's Cove. The presence of Federal masses in Lookout Valley caused Bragg to abandon Chattanooga at once, and the object of the manœuvre was thus accomplished; but owing to the want of good maps the Union army was at the same time exposed to great danger. The head of Thomas' column was engaged at Dug Gap, on the 11th, against the flank guard of Bragg's army, and at the time McCook was far away to the south, and Crittenden's corps, which had occupied Chattanooga on the 9th, was also at a distance. Thomas was isolated, but Rosecrans, like every other commander under whom he served, placed unbounded confidence in his tenacity, and if Bragg was wrong in neglecting to attack him on the 14th, subsequent events went far to disarm criticism. By the 18th of September Rosecrans had at last collected his army on Chickamauga Creek covering Chattanooga. But Bragg had now received heavy reinforcements, and lay, concentrated for battle, on the other side of the Creek. The terrain of the battle of Chickamauga (19th-20th of September) had little influence on its course. Both armies lay in the plain, the two lines roughly parallel. Bragg's intention was to force his attack home on Rosecrans' left wing, thus cutting him off from Chattanooga and throwing him back into the mountain country whence he had come. On the 19th a serious action took place between the Confederate right and Rosecrans' left under Thomas. On the 20th the real battle began. The Confederates, in accordance with Bragg's plans, pressed hard upon Thomas, to whom Rosecrans sent reinforcements. One of the divisions detached from the centre for this purpose was by inadvertence taken out of the first line, and before the gap could be filled the Confederate central attack, led by Longstreet and Hood, the fighting generals of Lee's army, and carried out by veteran troops from the Virginian battlefields, cut the Federal army in two. McCook's army corps, isolated on the Federal right, was speedily routed, and the centre shared its fate. Rosecrans himself was swept off the field in the rout of half of his army. But Thomas was unshaken. He re-formed the left wing in a semicircle, and aided by a few fresh brigades from Rossville, resisted for six hours the efforts of the whole Confederate army. Rosecrans in the meantime was rallying the fugitives far to the rear near Chattanooga itself. The fury of Bragg's assault spent itself uselessly on the heroic divisions under Thomas, who remained on the field till night and then withdrew in good order to Rossville. Here he remained on the 21st, imposing respect upon the victors. On the 22nd Rosecrans had re-established order, and Thomas fell back quietly to Chattanooga, whither Bragg slowly pursued. For the subsequent events of the campaign see CHATTANOOGA. The losses in the battle bear witness to a severity in the fighting unusual even in the American Civil War. Of 70,000 Confederates engaged at least 18,000 were killed and wounded, and the Federals lost 16,000 out of about 57,000. The battlefield has been converted into a national park, and was used during the Spanish American War (1898) as a place of mobilization for the U.S. volunteers.

CHICKASAWS, a tribe of North American Indians of Muskogean stock, now settled in the western part of Oklahoma. Their former range was northern Mississippi and portions of Tennessee. According to their own tradition and the evidence of philology, they are closely connected with the Creeks and Choctaws; and they believe that they emigrated with these tribes from the west, crossed the Mississippi, and settled in the district that now forms the north-east part of the state of that name. Here they were visited by De Soto in 1540. From the first they were hostile to the French colonists. With the English, on the other hand, their relations were more satisfactory. In 1786 they made a treaty with the United States; and in 1793 they assisted the whites in their operations against the Creeks. In the early years of the 19th century part of their territory was ceded for certain annuities, and a portion of the tribe migrated to Arkansas; and in 1832-1834, the remainder, amounting to about 1600, surrendered to the United States the 6,444,400 acres of which they were still possessed, and entered into a treaty with the Choctaws for incorporation with that tribe. In 1855, however, they effected a separation of this union, with which they had soon grown dissatisfied, and by payment to the Choctaws of $150,000 obtained a complete right to their present territory. In the Civil War they joined the Confederates and suffered in consequence; but their rights were restored by the treaty of 1865. In 1866 they surrendered 7,000,000 acres; and in 1873 they adopted their former slaves. They had an independent government consisting of a governor, a senate, a house of representatives; but tribal government virtually ceased in 1906. The Chickasaw Nation now consists of 4826 in 1900, and with the fully admitted “citizens,” i.e. the freed slaves and adopted whites, the whole nation amounted to some 10,000.

CHICKASHA, a city and the county-seat of Grady county, Oklahoma, U.S.A., near the Washita river, about 45 m. S. S. W. of Oklahoma city. Pop. (1900) 3200; (1907) 7800, including 1043 negroes; (1910) 10,00. Chickasha is served by the St Louis & San Francisco, the Chicago, Rock Island & Pacific and the Oklahoma Central railways. It is the trade centre of a very fertile section of the Washita Valley, whose principal products are Indian corn, cotton, fruits and vegetables and live-stock. The city has various manufactures, including flour, cottonseed oil, lumber, furniture and farm implements. Chickasha was founded in 1852 and was chartered as a city in 1859.

CHICKEN-POX (Varicella, a Low Latin diminutive of variolus), a specific contagious disease characterized by an eruption of vesicles in the skin. The disease usually occurs in epidemics, and is one of childhood, the patients being generally
between two and six years old. The incubation period is from ten to fifteen days; there are practically no prodromal symptoms, the only indication being a slight amount of fever for some twenty-four hours, after which the eruption makes its appearance. A number of raised red papules appear on the trunk, either on the back or chest; in from twelve to twenty-four hours these develop into tense vesicles filled with a clear fluid, which in another thirty-six hours or so becomes opalescent. During the fourth day these vesicles dry and shrivel up, and the scabs fall off, leaving as a rule no scar. Fresh spots appear during the first three days, so that at the end of that time they can be seen in all stages of growth and decay. The eruption is most apparent on the chest, but it also occurs on the face and limbs, and on the mucous membrane of the mouth and palate. The temperature begins to fall after the appearance of the rash, but a certain slight amount may persist after the disappearance of all symptoms. It rarely rises above 102 F. The disease runs a very favourable course in the majority of cases, and after effects are rare. One attack does not confer immunity, and in numerous cases one individual has had three attacks. The diet should be light, and the patient should be prevented from scratching the spots, which would lead to ulceration and scarring. After the first few days there is no necessity to confine the patient to bed. In the large majority of cases, it is easy to distinguish the disease from smallpox, but in certain patients it is very difficult. The chief points in the differential diagnosis are as follows. (I) In chicken-pox the rash is distributed chiefly on the trunk, and less on the limbs. (2) Some of the vesicles are oval, whereas in smallpox they are always hemispherical. They are also more superficial, and have not at the outset the hard shotty feeling of the more virulent disease. (3) The vesicles attain their full growth within twelve to twenty-four hours. (4) The pustules are usually monocular. (5) There is no prodromal period.

CHICLANA, or CHICLANA DE LA FRONTERA, a town of southern Spain, in the province of Cadiz, 12 m. by rail S.E. of Cadiz. Pop. (1900) 10,868. Chiclana occupies a fertile valley, watered by the river Lirio, and sheltered, on the north and south, by low hills covered with vines and plantations. It faces the gulf of Cadiz, 3 m. W., and, from its mild climate and pleasant surroundings, is the favourite summer residence of the richer Cadiz merchants; its hot mineral springs also attract many visitors. In the neighbourhood are the Roman ruins of Chiclana la Vieja, the town of Medina Sidonia (q.v.), and, about 5 m. S., the battlefield of Barrosa, where the British under Sir Thomas Graham (Lord Lyndoch) defeated the French under Marshal Victor, on the 5th of March 1811. Chiclana is the county town, and has a good station on the Madrid-Chiclana railway, which runs through the town. The rivers of Chiclana are the Bajo, which flows through the town, and the Atlantic, which runs past it to the sea. The town is noted for its fine grape and olive vintages, and was the birthplace of the great Spanish painter Tubi-ano Velazquez (1599-1660). Chiclana has a population of 14,050; on the railway.

Chiclayo was founded about 1436, was set off from Springfield as an independent township in 1848, and was chartered as a city in 1890. Chicopee Falls was the home of Edward Bellamy. The name of the city is an Indian word meaning "cedar-tree" or "birch-bark place."

CHICORY. The chicory or succory plant, Cichorium Intybus (natural order, Composite), in its wild state is a native of Great Britain, occurring most frequently in dry chalky soils, and by road-sides. It has a long fleshy tap-root, a rigid branching hairy stem rising to a height of 2 or 3 ft. —the leaves around the base being lobed and toothed, not unlike those of the dandelion. The flower heads are of a bright blue colour, few in number, and measure nearly an inch and a half across. Chicory is cultivated much more extensively on the continent of Europe—in Holland, Belgium, France and Germany—than in Great Britain; and as a cultivated plant it has three distinct applications. Its roots roasted and ground are used as a substitute for, adulterant of, or addition to coffee; both roots and leaves are employed as salads; and the plant is grown as a fodder or herbage crop which is greedily consumed by cattle. In Great Britain it is chiefly in its first capacity, in connexion with coffee, that chicory is employed. A large proportion of the chicory root used for this purpose is obtained from Belgium and other neighbouring continental countries; but a considerable quantity is cultivated in England, chiefly in Yorkshire. For the preparation of chicory the older stout white roots are selected, and after washing they are sliced up into small pieces and kiln-dried. In this condition the material is sold to the chicory roaster, by whom it is roasted till it assumes a deep brown colour; afterwards when ground it is in external characteristics very like coffee, but is destitute of its pleasing aromatic odour. Neither does the roasted chicory possess any trace of the alkaloid caffeine which gives their peculiar virtues to coffee and tea. The fact, however, that for over a hundred years it has been successfully used as a substitute for or recognized addition to coffee, while in the meantime innumerable other substances have been tried for the same purpose and abandoned, indicates that it is agreeable and harmless. It gives the coffee additional colour, bitterness and body. It is at least in very extensive and general use; and in Belgium especially its infusion is largely drunk as an independent beverage.

The blanched leaves are much esteemed by the French as a winter salad known by the name of Barbe de capucin. When intended for winter use, chicory is sown in May or June, commonly in drills, and the plants are thinned out to 4 in. apart. If at first the leaves grow very strong, they are cut off, perhaps in the middle of August, about an inch from the ground, so as to promote the production of new leaves, and check the formation of flower-stems. About the beginning of October the plants are raised from the border, and all the large leaves cut off; the roots are then thinned and are then planted pretty closely together in boxes filled with rich light mould, and watered as needful. When frost comes on, the boxes are protected by any kind of litter and halm. As the salad is wanted, they are removed into some place having a moderately increased temperature, and where there is no light. Each box affords two crops of blanched leaves, and these are reckoned fit for cutting when about 6 in. long. Another mode of obtaining the young leaves of this plant in winter is to sow seeds in a bed of light rich mould, or in boxes in a heat of from 55° to 60°, giving a gentle watering as required. The leaves will be fit to be cut in a fortnight after sowing, and the plants will afford a second crop.

In Belgium a variety of chicory called Wilaef is much preferred as a salad to the French Barbe de capucin. The seeds are sown and the plants thinned out like those of the ordinary sort. They are eventually planted in light soil, in succession, from the end of October to February. An acre will furnish a foot or more in depth, and covered over with from 2 to 3 ft. of hot stable manure. In a month or six weeks, according to the heat applied, the heads are fit for use and should be cut before they reach the manure. The plants might easily be forced in frames on a mild hot-bed, or in a mushroom-house, in the same way as sea-kale. In Belgium the fresh roots are boiled and eaten with butter, and throughout the Continent the roots are stored for use as salads during winter.
CHIDAMBARAM, or Chedumbum, a town of British India, in the South Arcot district of Madras, 7 m. from the coast and 141 m. S. of Madras by rail. Pop. (1901) 19,000. The pagodas at Chidambaram are the oldest in the south of India, and portions of them are gems of art. Here is supposed to have been the northern frontier of the ancient Chola kingdom, the successive capitals of which were Uriyur on the Cauvery, Combanooram and Tanjore. The principal temple is sacred to Siva, and is said to have been rebuilt or enlarged by a leper emperor, who came south on a pilgrimage and was cured by bathing in the temple tank; upwards of 60,000 pilgrims visit the temple every December. It contains a “hall of a thousand pillars,” one of numerous such halls in India, the exact number of pillars in this case being 984; each is a block of solid granite, and the roof of the principal temple is of copper-gilt. Three hundred of the highest-caste Brahmins live with their families within the temple enclosure.

CHIEF (from Fr. chef, head, Lat. caput), the head or upper part of anything, and so, in heraldry, the upper part of the escutcheon, occupying one-third of the whole. When applied to a leading personage, a head man or one having the highest authority, the term chief or chieftain (Med. Lat. capitans, O. Fr. chevetain) is principally confined to the leader of a clan or tribe. The phrase “in chief” (Med. Lat. in capite) is used in feudal law of the tenant who holds his fief direct from the lord paramount (see Feudalism).

CHIEMSEE, also called Bayrisches Meer, the largest lake in Bavaria, lying on a high plateau 1600 ft. above the sea, between the rivers Inn (to which it drains through the Alz) and Salzach. With a length of 6 and a breadth of 9 m., it has an area of about 33 sq. m., and contains three islands, Herrenwörth, Frauenwörth and Krautinsel. The first, which has a circumference of 64 m. and is beautifully wooded, is remarkable for the romantic castle which Louis II. of Bavaria erected here. It was the seat of a bishop from 1215 to 1805, and under Benedictine monks the lake is flat on the north and south sides, but its other banks are flanked by undulating hills, which command beautiful and extensive views. The waters are clear and it is well stocked with trout and carp; but the fishing rights are strictly preserved. Steamers ply on the lake, and the railway from Rosenheim to Salzburg skirts the southern shores.

CHIENG MAI, the capital of the Lao state of the same name and of the provincial division of Siam called Bayay, situated in 99° 6' E., 18° 46' N. The town, enclosed by massive but decaying walls, lies on the right bank of the river Me Ping, one of the branches of the Me Nam, in a plain 800 ft. above sea-level, surrounded by high, wooded mountains. It has streets intersecting at right angles, and an enceinte within which is the palace of the Chao, or hereditary chief. The east and west banks of the river are connected by a fine teak bridge. The American Presbyterian Mission, established here in 1869, has a large number of converts and has done much good educational work. Chiang Mai, which the Burmese have corrupted into Zinmè, by which name it is known to many Europeans, has long been an important trade centre, resorted to by Chinese merchants from the north and east, and by Burmese, Shan and Siamese from the west and south. It is, moreover, the centre of the teak trade of Siam, in which many Burmese and several Chinese and European firms are engaged. The total value of the import and export trade of the Bayav division amounts to about £25,000,000 a year. The Siamese high commissioner of Bayav division has his headquarters in Chiang Mai, and though the hereditary chief continues as the nominal ruler, as is also the case in the other Lao states of Nan, Prê, Lampun, Napawn Lampang and Tern, which make up the division, the government is entirely in the hands of that official and his staff. The government forest department, founded in 1866, has done good work in the division, and the conservator of forests has his headquarters in Chiang Mai. The headquarters of an army division are also situated here. A British consul resides at Chiang Mai, where, in addition to the ordinary law courts, there is an international court having jurisdiction in all cases in which British subjects are parties.

The population, about 20,000, consists mainly of Laos, with many Shan, a few Burmese, Chinese and Siamese and some fifty Europeans. Hill tribes (Ka) inhabit the neighbouring mountains in large numbers.

Chiang Mai was formerly the capital of a united Lao kingdom, which, at one time independent, afterwards subject to Burma and then to Siam, and later broken up into a number of states, has finally become a provincial division of Siam. In 1902 a rising of discontented Shan took place in Tayav which at one time seemed serious, several towns being attacked and Chiang Mai itself threatened. The disturbance was quelled and the malcontents eventually hunted out, but not without losses which included the commissioner of Prê and a European officer of gendarmerie.

CHIieri, a town and episcopal see of Piedmont, Italy, in the province of Turin, 13 m. S.E. by rail and 8 m. by road from the town of Turin. Pop. (1901) 21,926 (town), 13,803 (commune). In Gothic cathedral, founded in 1037 and reconstructed in 1455, is the largest in Piedmont, and has a 13th century octagonal baptistery. Chiieri was subject to the bishop of Turin in the 9th and 10th centuries, it became independent in the 11th century. In 1347 it submitted voluntarily to Count Amadeus VI. of Savoy to save itself from the marquis of Monferrato, and finally came under the dominion of Savoy in the 16th century. In 1785 it was made into a principality of the duke of Aosta. It was an early centre of trade and manufacture; and in the middle of the 15th century produced about 100,000 pieces of cotton goods per annum.

See L. Cibrario, Delle storie di Chiieri (Turin, 1855).

CHIeti, a city of the Abruzzi, Italy, the capital of the province of Chieti, and the seat of an archbishop, 114 m. E.N.E. of Rome by rail, and 9 m. W. of Castellammare Adriatico. Pop. (1901) 26,468. It is situated at a height of 1083 ft. above sea-level, 3 m. from the railway station, from which it is reached by an electric tramway. It is a chief seat of the Episcopate of Apennines and has a cathedral. The town spreads every side except the east, where the Adriatic is seen. It is an active modern town, upon the site of the ancient Teate Marrucinorum (q.v.), with woolen and cotton manufactories and other smaller industries. The origin of the see of Chieti dates from the 4th century, S. Justinus being the first bishop. The cathedral has been spoilt by restoration, and the decoration of the exterior is incomplete; the Gothic campanile of 1335 is, however, fine. The cathedral possesses two illuminated missals. Close by is the town hall, which contains a small picture gallery, in which, in 1905, was held an important exhibition of ancient Abruzzese art. The de Laurentis family possesses a private collection of some importance. To the north of Chieti is the octagonal church of S. Maria del Tricaglio, erected in 1317, which is said (without reason) to stand upon the site of a temple of Diana. The order of the Theatines, founded in 1524, takes its name from the city. Under the Lombards Chieti formed part of the Duchy of Benevento, it was reconstructed by Pippin in 808, but was soon rebuilt and became the seat of a count. The Normans made it the capital of the Abruzzi.

CHIFU, CHEEFOO, or Yen-Tai (as it is called by the natives), a seaport of northern China, on the southern coast of the Gulf of Chih-ki, in the province of Shan-tung, near the mouth of the Yih-ko, about 30 m. E. of the city of Teng-chow-fu. It was formerly quite a small place, and had only the rank of an unwalled village; but it was chosen as the port of Teng-chow, opened to foreign trade in 1858 by the treaty of Tientsin, and it is now the residence of a Tao-t'ai, or intendant of circuit, the centre of a gradually increasing commerce, and the seat of a British consulate, a Chinese custom-house, and a considerable foreign settlement. The native town is yearly extending, and though most of the inhabitants are small shop-keepers and coolies of the lowest class, the houses are for the most part well and solidly built of wood. The foreign settlement occupies a position between the native town and the sea, which neither affords a convenient access for shipping nor allows space for any great extension of area. Its growth, however, has hitherto been steady and rapid. Various streets have been laid out, a large
hotels erected for the reception of the visitors who resort to the place as a sanatorium in summer, and the religious wants of the community are supplied by a Roman Catholic and a Protestant church. Though the harbour is deep and extensive, and possessed of excellent anchorage, large vessels have to be moored at a considerable distance from the shore. Chi-fu has continued to show fair progress as a place of trade, but the total volume is inconsiderable, having regard to the area it supplies. In 1880 the total exports and imports were valued at £2,724,000, in 1890 they amounted to £4,228,000, and in 1904 to £4,909,000.

In 1893 there entered the port 909 vessels representing a tonnage of 835,428 tons, while in 1905 the number of vessels had risen to 1,842, representing a tonnage of 1,402,514 tons. The imports are mainly woolen and cotton goods, iron and opium, and the exports include bean cake, bean oil, peas, raw silk, straw-braid, walnuts, a coarse kind of vermicelli, vegetables and dried fruits. Communication with the interior is only by roads, which are extremely defective, and nearly all the traffic is by pack animals.

From its healthy situation and the convenience of its anchorage, Chi-fu has become a favourite rendezvous for the fleets of the European powers in Chinese waters, and consequently it has at times been an important coaling station. It lies in close proximity to Korea, Port Arthur and Wei-lai-Wei, and it shared to some extent in the excitement to which the military and naval operations in these quarters gave rise. The Chi-fu convention was signed here in 1876 by Sir Thomas Wade and Li-Hung-Chang.

**CHI-ALBANI—CHIHUAHUA**

CHI-ALBANI, the name of a Roman princely family of Sienese extraction descended from the counts of Arcenghesca. The earliest authentic mention of them is in the 13th century, and they first became famous in the person of Agostino Chiigi (d. 1520), an immensely rich banker who built the palace and gardens afterwards known as the Farnesina, decorated by Raphael, and was noted for the splendour of his entertainments; Pope Julius II. made him practically his finance minister and gave him the privilege of quartering his own (Della Rovere) arms with those of the Chiigi. Fabio Chiigi, on becoming pope (Alexander VII.) in 1655, conferred the Roman patriciate on his family, and created his nephew Agostino prince of Farnese and duke of Acria, and the emperor Leopold I. created the latter Reichsfurst (prince of the Holy Roman Empire) in 1659. In 1712 the family received the dignity of hereditary marshals of the Church and guardians of the conclave, which gave them a very great importance on the death of every pope. On the marriage in 1735 of another Agostino Chiigi (1710-1769) with Giulia Albani, heiress of the Albani, a Venetian patrician family, said to be of Albanian origin, her name was added to that of Chiigi. The family owns large estates in Siena.

See A. von Reumont, Geschicichte der Stadt Rom, vol. iii. (Berlin, 1866); Amonasch de Gotha.

CHIWELL, a parish and residential district in the Epping parliamentary division of Essex, England, with railway connections at the principal station and the principal branch of the Eastern railway. 12 m. N.E. from London. Pop. (1901) 2508. The old village church of St Mary, principally Perpendicular, has a Norman south door. The village lies in a branch of the Roding valley, fragments of Hainault Forest lying to the south and east, bordering the village of Chigwell Row. The village of Chigwell appears in the Domesday survey. The pleasant scenery of the neighbourhood, which attracts large numbers both of visitors and of residents from London, is described in Dickens's novel, Barnaby Rudge, and the King's Head Inn, Dickens's "Maypole," still stands. The old grammar school, founded by Samuel Harris, archbishop of York (d. 1631), whose fine memorial brass is in St Mary's church, has become one of the minor modern institutions of the English public school type. William Penn attended school at Chigwell from his home at Wellesden.

CHIH-ALBANI ("Direct Rule"), the metropolitan province of China, in which is situated Peking, the capital of the empire. It contains eleven prefectural cities, and occupies an area of 58,950 sq. m. The population is 20,900,000, the vast majority of whom are resident in the plain country. This province forms part of the great delta plain of China proper, 20,000 sq. m. of which are within the administrative boundaries; the remainder of the territory consists of the mountain ranges which define its northern and western frontier. The plain of Chih-li is formed principally by detritus deposited by the Pei-ho and its tributary the Hun-ho ("muddy river"), otherwise known as the Yung-tung-ko, and other streams having their sources in mountains of Shan-si and other ranges. It is bounded E. by the Gulf of Chih-li and Shan-tung, and S. by Shan-tung and Ho-nan. The proportion of Mahomedans among the population is very large. In Peking there are said to be as many as 20,000 Mahomedan families, and in Pao-tung Fu, the capital of the province, there are about 1000 followers of the prophet. The extremes of heat and cold in Chih-li are very marked. During the months of December, January and February the rivers are frozen up, and even the Gulf of Chih-li is fringed with a broad border of ice. There are four rivers of some importance in the province: the Pei-ho, with the Hun-ho, which rises in the mountains in Mongolia and, flowing to the west of Peking, forms a junction with the Pei-ho at Tientsin; the Shang-si-ho, which rises in Shan-si, and after running a parallel course to Shang-si-ho on the south, empties itself in the same way into the Hun-ho; and the Lan-ho, which rises in Mongolia, enters the province on the north-east after passing to the west of Jehol, passes the city of Yung-p'ing Fu in its course (which is south-easterly) through Chi-li, and from thence winds its way to the north-eastern boundary of the Gulf of Chih-li. The province contains three lakes of considerable size. The largest is the Ta-lu-tsze Hu, which lies in 37° 40′ N. and 115° 20′ E.; the second in importance is one which is situated to the east of Pao-tung Fu; and the third is the Tu-lu-tsze Hu, which lies east by north of Shun-te Fu. Four high ranges radiate from Peking, one leading to Urga by way of Suan-hwa Fu, which passes through the Great Wall at Chang-ku-kow; another, which enters Mongolia through the Ku-pei Kow to the north-east, and after continuing that course as far as Feng-nung turns in a north-western direction to Dolonom; a third striking due east by way of Tung-chow and Yung-p'ing Fu to Shan-hai Kwan, the point where the Great Wall terminates on the coast; and a fourth which trends in a south-western direction to Pao-tung Fu and on to T'ai-yuen Fu in Shan-si. The mountain ranges to the north of the province abound with coal, notably at Chai-tang, T'ai-gan-shan, Miao-gan-ling, and Fu-tao in the Si-shan or Western Hills. "At Chai-tang," wrote Baron von Richthofen, "I was surprised to walk over a regular succession of coal-bearing strata, the thickness of which, estimating it step by step as I proceeded gradually from the lowest to the highest strata, exceeds 7000 ft." The coal here is anthracite, as also that at T'ai-gan-shan, where are found beds of greater thickness than any in China. In Suan-hwa Fu coal is also found, but not in such quantities as in the others above named. Iron and silver also exist in small quantities in different parts of the province, and hot and warm springs are very common at the foot of the hills along the northern and western edges of the province. The principal agricultural products are wheat, kao-liang, oats, millet, maize, pulse and potatoes. Fruits and vegetables are also grown in large quantities. Of the former the chief kinds are pears, apples, plums, apricots, peaches, persimmons and melons. Tientsin is the Treaty Port of the province.

CHIHUAHUA, a northern frontier state of Mexico, bounded N. and N.E. by the United States (New Mexico and Texas), E. by Coahuila, S. by Durango, and W. by Sinaloa and Sonora. Pop. (1893) 260,006; (1900) 327,784. Area, 87,802 sq. m. The surface of the state is in great part an elevated plateau, sloping gently toward the Rio Grande. The western side, however, is much broken by the Sierra Madre and its spurs, which form elevated valleys of great fertility. An arid sandy plain...
extending from the Rio Grande inland for 300 to 350 m. is quite
literate. Where irrigation is not used, there is
little rainfall in this region and the climate is hot and dry.
The more elevated plateaus and valleys have the heavier rainfall,
but the average for the state is barely 30 in.; an impermeable
clay substratum prevents its absorption by the soil, and the
bare surface carries it off in torrents. The great Bolson de
Mapimi depression, in the S.E. part of the state, was once
considered to be an unreclaimable desert, but experiments with
irrigation have shown its soil to be highly fertile, and the con-
version of the narrow valleys of the sierras on the west into
irrigation reservoirs promises to reclaim a considerable part of
its area. The only river of consequence is the Conchos, which
flows north and north-east into the Rio Grande across the whole
length of the state. In the north there are several small streams
flowing northward into lakes. Agriculture has made little
progress in Chihuahua, and the scarcity of water will always
be a serious obstacle to its development outside the districts
where irrigation is practicable. The climate and soil are favour-
able to the production of wheat, Indian corn, beans, indigo,
cotton and grapes, from which wine and brandy are made.
The greatest wine-producing district is in the vicinity of
Ciudad Juárez.
Stock-raising is an important industry in the
mountainous districts of the west, where there is excellent
pasturage for the greater part of the year. The principal in-
dustry of the state, however, is mining—its mineral resources
including gold, silver, copper, mercury, lead and coal. The
silver mines of Chihuahua are among the richest in Mexico, and
include the famous mining districts of Batopilas, Chihuahuailla,
Coshiurichic, Jesús María, Parral, and Santa Eulalia or
Chihuahua el Viejo. There are more than one hundred of these
mines, and the total annual yield at the end of the 19th century
was estimated at $4,500,000. The state is traversed from
north to south by the Mexican Central railway, and there are
short branches to some of the mining districts.
Chihuahua originally formed part of the province of Nueva
Viscaya, with Durango as the capital. In 1777 the northern
provinces, known as the Provincias Internas, were
separated into the viceroyalty, and in 1786 the northern territory
was organized as an independent state, but Chihuahua was not separated from Durango
until 1823. An effort was made to overthrow Spanish authority
in 1810, but its leader Hidalgo and two of his lieutenants were
captured and executed, after which the province remained
passive until the end of the struggle. The people of the state
have been active partizans in most of the revolutionary outbreaks
in Mexico, and in the war of 1862–66 Chihuahua was loyal to
Juárez. The principal towns are the capital Chihuahua, El
Parral, 120 m. S.S.E. of the state capital, in a mining district
(pop. 14,748 in 1900), Ciudad Juárez and Jimenez, 120 m. S.E.
of Chihuahua (pop. 888 in 1900).
CHIHUAHUA, a city of Mexico, capital of the above state,
on the Chihuahua river, about 1000 m. N.W. of Mexico City
and 225 m. S. by E. of El Paso, Pop. (1895) 18,279; (1900)
30,405. The city stands in a beautiful valley opening northward
and hemmed in on all other sides by spurs of the Sierra Madre.
It is 4635 ft. above sea-level, and its climate is mild and healthy.
There is a large regular and broad street, and a handsome
plaza with a monument to Hidalgo and his companions of the
revolution of 1810, who were executed here. The most
noteworthy of its public buildings is the fine old parish church
of San Francisco, begun in 1717 and completed in 1780, one of the
best specimens of 18th-century architecture in Mexico. It was
built, it is said, with the proceeds of a small tax on the output of
the Santa Eulalia mine. Other prominent buildings are the
government palace, the Porfirio Diaz hospital, the old Jesuit
College (now occupied by a modern institution of the same
character), the mint, and an aqueduct built in the 18th century.
Chihuahua is a station on the Mexican Central railway, and has
tramways and telephones. Mining is the principal occupation
of the adjoining district, the famous Santa Eulalia or Chihuahua
el Viejo mines being about 12 m. from the city. Next in
importance is agriculture, especially fruit-growing. Manufacturing
is making good progress, especially the weaving of cotton fabrics
by modern methods. The manufacture of cotton and woolen
goods are old industries in Chihuahua, but the introduction of
American skill and capital toward the end of the 19th century
placed them on an entirely new footing. The manufacture of
gunpowder for mining operations is another old industry.
Chihuahua was founded between 1703 and 1705 as a mining
town, and was made a villa in 1715 with the title San Felipe el
Real de Chihuahua. Because of the rich mines in its vicinity
it soon became one of the most prosperous towns in northern
Mexico, although the state was constantly raided by hostile
Indians. In 1763 it had a population of nearly 5000. The war
of independence was followed by a period of decline, owing to
political disorder and revolution, which lasted until the presidency
of General Porfirio Diaz. In the war between Mexico and the
United States, Chihuahua was captured on the 1st of March
1847, by Colonel A. W. Doniphan, and again on the 7th of March
by General Price. In 1864 President Juárez made the city his
provisional capital for a short time.
CHILAS, a hill village in the North-West Frontier Province
of India, 40 m. above a fort on the left bank of the Indus, about
50 m. below Bunji, 4100 ft. above sea-level. It was occupied by a British force early in 1893, when a determined
attack was made on the place by the Kohistanis from the Indus
valley districts to the south-west, aided by contingents from
Darel and Tangir west of Gilgit and north of the Indus. Its
importance consists in its position with reference to the Kashmir-
Gilgit route via Astor, which it flanks. It is now connected
with Bunji by a metalled road. Chilas is also important from its
command of a much shorter and more direct route to Gilgit
from the Punjab frontier than that of Kashmir and the Burzil
pass. By the Kashmir route Gilgit is 400 m. from the rail-head
at Rawalpindi. The Kagan route would bring it 100 m. nearer,
but the unsettled condition of the country through which the
road passes has been a bar to its general use.
CHILBLAINS (or Kibe; Erythema pernio), a mild form of
frostbite, affecting the fingers or toes and other parts, and causing
a painful inflammatory swelling, with redness and itching of
the skin. Its points to be noticed in its aetiology are (1) that the lesions occur in the extremities of the circulation,
and (2) that they are usually started by rapid changes from
heat to cold or vice versa. The treatment is both general and
local. In the general treatment, if a history of blanching fingers
(fingers or hands going "dead") can be obtained, the chilblains
may be regarded as mild cases of Raynaud's disease, and these
improve markedly under a course of nitrates. Cardiac tonics are
often helpful, especially in those cases where there is some
attendant lesion of the heart. But the majority of cases improve
wonderfully on a good course of a calcium salt, e.g. calcium
lactate or chloride; fifteen grains three times a day will answer
in most cases. The patient should wash in soft tepid water, and
avoid extremes of heat and cold. In the local treatment, two
drugs are of great value in the early congestive stage—ichthyol
and formalin. Ichthyol, 10 to 20 % in lanoline spread on linen
and worn at night, often dispels an attack at the beginning.
Formalin is equally efficacious, but requires more skill in its use.
It can be used as an ointment, 10 to 50 % for delicate skins, stronger
for coarser skins. It should be replaced occasionally by lanoline.
If the stage of ulceration has been reached, a paste made from
the following prescription, spread thickly on linen and frequently
changed, soon cures—Hydrag. ammoniat. gr. v., ichthyol
mX, pulversin zinci oxidzi5iv, vaseline 3ss.
CHILD, SIR FRANCIS (1642–1713), English banker, was a
Wiltshire man, who, having been apprenticed to a goldsmith,
became himself a London goldsmith in 1664. In 1671 he married
Elizabeth (d. 1720), daughter of another goldsmith named
William Wheeler (d. 1693), and with his wife's stepfather,
Robert Blanchard (d. 1681), took over about the same time the
business of goldsmiths hitherto carried on by the Wheelers.
This was the beginning of Child's Bank. Child soon gave up
the business of a goldsmith and confined himself to that of a
banker. He inherited some wealth and was very successful in
CHILD, F. J.—CHILD, L. M.

business; he was jeweller to the king, and lent considerable sums of money to the government. Being a freeman of the city of London, Child was elected a member of the court of common council in 1683; in 1689 he became an alderman, and in the same year a knight. He served as sheriff of London in 1691 and as lord mayor in 1699. His parliamentary career began about this time. In 1698 he was chosen member of parliament for Devizes and in 1702 for the city of London, and was again returned for Devizes in 1705 and 1710. He died on the 4th of October 1713, and was buried in Fulham churchyard. Sir Francis, who was a benefactor to Christ's hospital, bought Osterley Park, near Isleworth, now the residence of his descendant the earl of Jersey.

Child had twelve sons. One, Sir Robert, an alderman, died in 1721. Another, Sir Francis (c. 1684-1740), was lord mayor of London in 1732, and a director of the East India Company. He was chosen member of parliament for the city of London in 1722, and was member for Middlesex from 1727 until his death. After the death of the younger Sir Francis at Fulham on the 20th of April 1740 the banking business passed to his brother Samuel, and the bank is still owned by his descendants, the principal proprietor being the earl of Jersey. Child's Bank was at that time located at the Marygold, next Temple Bar in Fleet Street, London; and the present bank occupies the site formerly covered by the Marygold and the adjacent Devil tavern.

CHILD, FRANCIS JAMES (1825-1890), American scholar and educationist, was born in Boston on the 1st of February 1825. He graduated at Harvard in 1846, taking the highest rank in his class in all subjects; was tutor in mathematics in 1846-1848; and in 1848 was transferred to a tutorship in history, political economy and English. After two years of study in Europe, in 1851 he succeeded Edward T. Channing as Boylston professor of rhetoric, oratory and eloquence. Child studied the English drama (having edited Four Old Plays in 1848) and Germanic philology, the latter at Berlin and Göttingen during a leave of absence, 1849-1853; and he took general (1848-1853). He edited Spenser (5 vols., Boston, 1855), and at one time planned an edition of Chaucer. Child undertook himself with a treatise, in the Memoirs of the American Academy of Arts and Sciences for 1863, entitled “Observations on the Language of Chaucer's Canterbury Tales,” which did much to establish Chaucerian grammar, pronunciation and scansion as now generally understood. His largest undertaking, however, grew out of an original collection, in his British Poets series, of English and Scottish Ballads, selected and edited by himself, in eight small volumes (Boston, 1857-1888). Thence-forward the leisure of his life—much increased by his transfer, in 1876, to the new professorship of English—was devoted to the comparative study of British vernacular ballads. He accumulated, in the university library, one of the largest folklore collections in existence, studied manuscript rather than printed sources, and carried his investigations into the ballads of all other tongues, meanwhile giving a sedulous but conservative hearing to popular versions still surviving. At last his collection was published as The English and Scottish Popular Ballads, at first in ten parts (1882-1888), and then in five quarto volumes, which remain the authoritative treasury of their subject. Professor Child worked—and overworked—to the last, dying in Boston on the 11th of September 1896, having completed his task save for a general introduction and bibliography. A sympathetic biographical sketch was prefixed to the work by his pupil and successor George L. Kittredge.

CHILD, SIR JOHN (d. 1690), governor of Bombay, and in fact if not in name the first governor-general of the British settlements in India, was born in London. He was sent as a little boy to his uncle, the chief of the factory at Raispur; and in 1682 was appointed chief of the East India Company's affairs at Surat and Bombay, while at the same time his brother, Sir Josiah Child (q.v.), was governor of the company at home. The two brothers showed themselves strong men and guided the affairs of the company through the period of struggle between the Moguls and Marthatts. They have been credited by history with the change from unarmed to armed trade on the part of the company; but as a matter of fact both of them were too light to quarrel with the Mogul. War broke out with Aurangzeb in 1689, but in the following year Child had to sue for peace, one of the conditions being that he should be expelled from India. He escaped this expulsion by his death in 1690.

CHILD, SIR JOSIAH (1630–1690), English merchant, economist and governor of the East India Company, was born in London in 1630, the second son of Richard Child, a London merchant of old family. After serving his apprenticeship in the business, to which he succeeded, he started on his own account at Portsmouth, as victualler to the navy under the Commonwealth, when about twenty-five. He amassed a comfortable fortune, and became a considerable stock-holder in the East India Company, his interest in India being accentuated by the fact that his brother John (q.v.) was making his career there. He was returned to parliament in 1659 for Petersfield; and in later years sat for Dartmouth (1673-1678) and for Ludlow (1687-1687). He was made a baronet in 1678. His advocacy, both by speech and by pen, under the pseudonym of Philopatris, of the East India Company's claims to political power, as well as to the right of restricting competition with its trade, brought him to the notice of the shareholders, and he became a director in 1677, and, subsequently, deputy-governor and governor. In this latter capacity he was for a considerable time virtually the sole ruler of the company, and directed its policy as if it were his own private business. He and his brother have been credited with the change from unarmed to armed traffic; but the actual renunciation of the Roe doctrine of unarmed traffic by the company was resolved upon in January 1686, under Governor Sir Joseph Ash, when Child was temporarily out of office. He died on the 22d of June 1690. Child made several important contributions to the literature of economics; especially Brief Observations concerning Trade and the Interest of Money (1668), and A New Discourse of Trade (1668 and 1669). He was a moderate in those days of the "mercantile system," and has sometimes been regarded as a sort of pioneer in the development of the free-trade doctrines of the 18th century. He made various proposals for improving British trade by following Dutch example, and advocated a low rate of interest as the "causa causans of all the other causes of the riches of the Dutch people." This low rate of interest he thought should be created and maintained by public authority. Child, whilst adhering to the doctrine of the balance of trade, observed that a people cannot always sell to foreigners without ever buying from them, and denied that the export of the precious metals was necessarily detrimental. He had the mercantilist partiality for a numerous population, and became prominent with a new scheme for the relief and employment of the poor; it is noteworthy also that he advocated the reservation by the mother country of the sole right of trade with her colonies. Sir Josiah Child's eldest son, Richard, was created Viscount Castlemain in 1718 and earl of Tyne in 1731.

CHILD, LYDIA MARIA (1802-1886), American author, was born at Medford, Massachusetts, on the 11th of February 1802. She was educated at an academy in her native town and by her brother Convers Francis (1795-1863), a Unitarian minister and from 1812 to 1863 Parkman professor in the Harvard Divinity School. Her first stories, Hobomok (1824) and The Rebels (1825), were popular successes. She was a schoolmistress until 1828, when she married David Lee Child (1794-1874), a brilliant but erratic Boston lawyer and journalist. From 1826 to 1834 she edited The Juvenile Miscellany, the first children's monthly periodical in the United States. About 1831 both she and her husband began to identify themselves with the anti-slavery cause, and in 1833 she published An Appeal for that Class of Americans called Africans, a stirring portrayal of the evils of slavery, and an argument for immediate abolition, which had
CHILD

a powerful influence in winning recruits to the anti-slavery cause. Henceforth her time was largely devoted to the anti-slavery cause. From 1840 to 1844, assisted by her husband, she edited the Anti-Slavery Standard in New York City. After the Civil War she wrote much in behalf of the freedmen and of Indian rights. She died at Wayland, Massachusetts, on the 20th of October 1886. In addition to the books above mentioned, she wrote many pamphlets and short stories and The (American) Frugal Housewife (1829), one of the earliest American books on domestic economy, The Mother's Book (1831), a pioneer cook-book republished in England and Germany, The Girls' Own Book (1831), History of Women (2 vols., 1832), Good Wives (1833), The Anti-Slavery Catechism (1836), Philanth (1836), a romance of the age of Pericles, perhaps her best book, Letters from New York (2 vols., 1843-1845), Fact and Fiction (1847), The Power of Kindness (1831), Isaac T. Hopper: A True Life (1853), The Progress of Religious Ideas through Successive Ages (3 vols., 1853), Autumn Leaves (1857), Looking Toward Sunset (1864), The Freedman's Book (1865), A Romance of the Republic (1867), and Aspirations of the World (1878).

See The Letters of Lydia Maria Child, with a Biographical Introduction by J. G. Whittier (Boston, 1883); and a chapter in T. W. Higginson's Contemporaries (Boston, 1899).

CHILD, the common term for the offspring of human beings, generally below the age of puberty; the term is the correlative of "parent," and applies to either sex, though some early dialectical uses point to a certain restriction to a girl. The word is derived from the A.S. *cil*?, an old Teutonic word found in English only, in other Teutonic languages kind and its variants being used, usually derived from the Indo-European root *ken*, seen in Gr. γενος, Lat. genus, and Eng. "kin"; *cil*? has been held to be a modification of the same root, but the true root is *kilth*, seen in Goth. kilthel, womb, an origin which appears in the expressions "child-birth," "to be with child," and the like; the plural in A.S. was *cil*?, and later *cildr*, which in northern M.E. became *children* or *childer*, a form dialectically extant, and in southern English *children* or *children* (with the plural termination *en*, as in "brethren"). There are several particular uses of "child" in the English version of the Bible, as of a young man in the "Song of the three holy children," of descendants or members of a race, as in "children of Abraham," and also to express origin, giving a description of character, as "children of darkness." During the 13th and 14th centuries "child" was used, in a sense almost amounting to a title of dignity, of a young man of noble birth, probably preparing for knighthood. In the York Mysteries of about 1440 (quoted in the New English Dictionary) occurs "be he churl or child," obviously referring to gentle birth, cf. William Bellenden's translation (1553) of Livy (ii. 124) "than was in Rome ane nobill child,... namit Caicus Mucius." The spelling "child" is frequent in modern usage to indicate its archaic meaning. Familiar instances are in the line of an old ballad quoted in King Lear, "child Roland to the dark tower came," and in Byron's Child Harold. With this use may be compared the Spanish and Portuguese Infante and Infantes, and the early French use of Vaucl (q.v.).

Child-study.—The physical, psychological and educational development of children, from birth till adulthood, has provided material in recent years for what has come to be regarded as almost a distinct part of comparative anthropological or sociological science, and the literature of adolescence (q.v.) and of "child-study" in its various aspects has attained considerable proportions. In England the British Child Study Association was founded in 1894, its official organ being the Pedagogist, while similar work is done by the Childhood Society, and, to a certain extent, by the Parents' National Educational Union (which issues the Parents' Review). In America, where specially valuable work has been done, several universities have encouraged the study (notably Chicago, while under the auspices of Professor John Dewey); and Professor G. Stanley Hall's initiative has led to elaborate inquiries, the principal periodical for the movement being the Pedagogical Seminary. The impetus to this study of the child's mind and capacities was given by the classic work of educationists like J. A. Comenius, J. H. Pestalozzi, and F. W. A. Froebel, but more recent writers have carried it much further, notably W. T. Preyer (The Mind of the Child, 1851), whose psychological studies distinguish him as one of the chief pioneers in new methods of investigation. Other authorities of first-rate importance (their chief works only being given here) are J. Sully (Studies of Childhood, 1860), Earl Barnes (Studies in Education, 1856, 1904), J. M. Baldwin (Mental Development in the Child and the Race, 1893), Sigismund (Kind und Welt, 1847), A. F. Chamberlain (The Child, 1900), G. Stanley Hall (Adolescence, 1904; he from 1882 been the leader in America of such investigations), H. Holman and R. Langdon Down (Practical Child Study, 1890), E. A. K. Parkin (Fundamentals of Child-study, 1902), and Prof. Tracy of Toronto (Psychology of Childhood, 5th ed., 1901); while among a number of contributions worth particular attention may be mentioned W. B. Drummond's excellent summary, Introduction to Child Study (1907), which deals succinctly with methods and results; Irving King's Psychology of Child Development (1906, useful for its bibliography); Prof. David R. Major's First Steps in Mental Growth (1906); and Miss M. Shinn's Notes on the Development of a Child (1893) and Mrs Louise E. Hogan's Study of a Child (1898), which are noteworthy among individual and methodical accounts of what children will do. In such books as those cited a great deal of important material has been collected and analysed, and a number of conclusions suggested which bear both on psychology and the science of education; but it must be borne in mind, as regards a great deal of the voluminous literature of the subject, that it is often more pertinent to general psychology and hygiene than to any special conclusions as to the essential nature of a child—whatever a "child" generically may be as the special object of a special science. The child, after all, is in a transition stage to an adult, and there is often a tendency in modern "child students" to interpret the phenomena exhibited by a particular child with a pari pris, or to exaggerate child-study—which is really interesting as providing the knowledge of growth towards full human equipment—as though it involved the discovery of some distinct form of animal, of separate value on its own account.

Growth.—Into the psychical characteristics and development of the child and all the interesting educational problems involved it is impossible to enter here, and reference must be made to the works cited above. But a knowledge of the more important features of normal physical development has a constant importance. Some of these, as matters of comparative physiology or pathology, are dealt with in other articles in this work. One of these chief matters of interest is weight and height, and this is naturally affected by race, nutrition and environment. But while the standard in different countries somewhat differs, the British average for healthy children may here be followed. At birth the average weight of a baby is a little over 7 lb and the length about 20 in. The following are the averages for weight and height, taking the age in years of the child at the last birthday:

**Height, in inches.**

1. The child-study as above in this article is based chiefly on S. B. Crookes’ Child-study, 1891, and on the periodical publications of the British Child Study Association. The references are taken from the American Psychological Association's Annual Report, 1895.
CHILDEBERT—CHILDERS, H. C. E. 137

See also Children, Law relating to: Children's Courts; Children's Games; Infant; &c.

CHILDEBERT, the name of three Frankish kings.

CHILDEBERT I. (d. 558) was one of the four sons of Clovis. In the partition of his father's realm in 511 he received as his share the town of Paris, and the country to the north as far as the river Soone, and to the west as far as the English Channel, with the Armorican peninsula. In 524, after the murder of Chlodomer's children, Childebert annexed the cities of Chartres and Orleans. He took part in the various expeditions against the kingdom of Burgundy, and in 534 received as his share of the spoils of that kingdom the towns of Macon, Geneva and Lyons. When Vitiges, the king of the Ostrogoths, ceded Provence to the Franks in 555, the possession of Arles and Marseilles was guaranteed to Childebert by his brothers. Childebert also made a series of expeditions against the Visigoths of Spain; in 542 he took possession of Pampeluna with the help of his brother Clotaire I., and besieged Saragossa, but was forced to retreat. From this expedition he brought back to Paris a precious relic, the tunic of St Vincent, in honour of which he built at the gates of Paris the famous monastery of St Vincent, known later as St Germain-des-Prés. He died without issue in 558, and was buried in the abbey he had founded, where his tomb has been discovered.

CHILDEBERT II. (570-595), king of Austrasia, was a son of Sigebert. When his father was assassinated in 575, Childebert was taken from Paris by Gundobald, one of his faithful leudes, to Metz, where he was recognized as sovereign. He was then only five years old, and during his long minority the power was disputed between his mother Brunhilda and the nobles. Chilperic, king at Paris, and King Gontran of Burgundy, sought alliance with Childebert, who was adopted by both in turn. But after the assassination of Chilperic in 584, and the dangers occasioned to the Frankish monarchy by the expedition of Gundobald in 585, Childebert threw himself unreservedly into the arms of Gontran. By the pact of Andelot in 587 Childebert was recognized as Gontran's heir, and with his uncle's help he quelled the revolts of the nobles, and succeeded in seizing the castle of Woëvre. Many attempts were made on his life by Fredegund, who was anxious to secure Gontran's inheritance for her son Clotaire II. On the death of Gontran in 592 Childebert annexed the kingdom of Burgundy, and even contemplated seizing Clotaire's estates and becoming sole king of the Franks. He died, however, in 595. Childebert II. had had relations with the Byzantine empire, and fought in 593 in the name of the emperor Maurice against the Lombards in Italy.

CHILDEBERT III. was one of the last and feeblest of the Merovingians. A son of King Theuderich III., he succeeded his brother Clovis III. in 695, and reigned until 711.

CHILDERIC, the name of three Frankish kings.

CHILDERIC I. (c. 437-481), king of the Salian Franks, succeeded his father Merwich (Merwing) as king about 457. With his tribe he was established around the town of Tournai, on lands which he had received as a feodatus of the Romans, and for some time he kept the peace with his hosts. About 475, in conjunction with the Roman general Egidius, he fought against the Visigoths, who hoped to extend their dominion along the banks of the Loire; after the death of Egidius he assisted Count Paul in attempting to check an invasion of the Saxons. Paul having perished in the struggle, Childeric delivered Angles from some Saxons, followed them to the islands at the mouth of the Loire, and massacred them there. He also stopped a band of the Alamanni who wished to invade Italy. These are all the facts known about him. The stories of his expulsion by the Franks; of his stay of eight years in Thuringia with King Basin and his wife Basine; of his return when a faithful servant advised him that he could safely do so by sending him half a piece of gold which he had broken with him; and of the arrival at Tournai of Queen Basine, whom he married, are entirely legendary. After the fall of the Western Empire in 476 there is no doubt that Childeric regarded himself as freed from his engagements towards Rome. He died in 482 and was buried at Tournai, leaving a son Clovis (q.v.), afterwards king of the Franks. His tomb was discovered in 1653, when numerous precious objects, arms, jewels, coins and a ring with a figure of the king, were found.

CHILDERIC II. (c. 563-673), king of Austrasia, was a son of the Frankish king Clovis II., and in 606, although a child, was proclaimed king of Austrasia, while his brother, Clotaire III., ruled over the rest of the dominions of Clovis. After the death of Clotaire in 670 he became ruler of the three Frankish kingdoms, Austrasia, Neustria and Burgundy, but soon quarrelled with some supporters in Neustria, and was assassinated whilst hunting. He was buried at St Germain near Paris.

CHILDERIC III. (d. 751), king of the Franks, was the last king of the Merovingian dynasty. The throne had been vacant for seven years when the mayors of the palace, Carlemann and Pippin the Short, decided in 743 to recognize Childeric as king. We cannot say whose son he was, or what bonds bound him to the Merovingian family. He took no part in public business, which was directed, as before, by the mayors of the palace. When in 749 he was forced to retire, and was made abbot of Corbie, Pippin resolved to take the royal crown for himself; taking the decisive step in 751 after having received the celebrated answer of Pope Zacharias that it were better to name king him who possessed the power than him who possessed it not. Childeric was dethroned and placed in the monastery of St Omer; his son, Theuderich, was imprisoned at Saint-Wandrille.

CHILDERS, HUGH CULLING EARLLEY (1827-1896), British statesman, was born in London on the 25th of June 1817. On leaving Cambridge he went out to Australia (1830), and became a member of the government of Victoria, but in 1857 returned to England as agent-general of the colony. Entering parliament in 1850 as Liberal member for Pontefract (a seat that he continued to hold till 1885), he became civil lord of the admiralty in 1864, and in 1865 financial secretary to the treasury. Childers occupied a succession of prominent posts in the various Gladstone ministries. He was first lord of the admiralty from 1868 to 1871, and as such inaugurated a policy of retenchment. Ill-health compelled his resignation of office in 1871, but next year he returned to the ministry as chancellor of the duchy of Lancaster. From 1880 to 1882 he was secretary for war, a post he accepted somewhat unwillingly; and in that position he had to bear the responsibility for the reforms which were introduced into the war office under the parsimonious conditions which were then part of the Liberal creed. During his term of office the Egyptian War occurred, in which Childers acted with creditable energy; and also the Boer War, in which he and his colleagues showed to less advantage. From 1882 to 1885 he was chancellor of the exchequer, and the beer and spirit duty in his budget of the latter year was the occasion of some very severe criticism. Defeated at the general election of 1885 at Pontefract, he was returned as a Home Ruler (one of the few Liberals who adopted this policy before Mr Gladstone's conversion) in 1886 for South Edinburgh, and was home secretary in the ministry of 1886. When the first Home Rule bill was introduced he demurred privately to its financial clauses, and their withdrawal was largely due to his threat of resignation. He retired from parliament in 1892, and died on the 20th of January 1896, his last piece of work being the drafting of a report for the royal commission on Irish financial relations, of which he was chairman. Childers was a capable and industrious administrator of the old Liberal school, and he did his best, in the political conditions then prevailing, to improve the naval and military administration while he was at the admiralty and war office. His own bent was towards finance, but no
to be permanently injured (Offences against the Person Act of 1861, s. 27), and the neglect or ill-treatment of apprentices or servants (same act, s. 26, and Conspiracy and Protection of Property Act 1875, s. 6). By the Poor Law Amendment Act 1868, parents were rendered summarily punishable who wilfully neglected to provide adequate food, clothing, medical aid or lodging for their children under fourteen years of age in their custody, whereby the health of the child was or was likely to be seriously injured. This enactment (now superseded by later legislation) made no express exception in favour of parents who had not sufficient means to do their duty without resort to the poor law, and was construed as imposing criminal liability on parents whose peculiar religious tenets caused them advisedly to refrain from calling in a doctor to a sick child.

The chief progress in the direction of adequate protection for children prior to 1889 lay less in positive legal enactment on the subject than in the institution of an effective system of police, whereby it became possible to discover and repress cruelty punishable under the ordinary law. It is quite inaccurate to say that children had very few rights in England, or that animals were better protected. But with the establishment of the police force, and in the absence of any proper system of public prosecution, it is undeniable that numberless cases of neglect and ill-treatment went unpunished and were treated as nobody's business, because there was no person ready to undertake in the public interest the protection of the children of cruel or negligent parents. In 1889 a statute was passed with the special object of preventing cruelty to children. This act was superseded in 1894 by a more stringent act, which was repealed by the Prevention of Cruelty to Children Act 1904, in its turn superseded for the most part by the Children Act 1908, which introduced many new provisions in the law relating to children and specifically deals with the offence of "cruelty" to them. This offence can only be committed by a person over sixteen in respect of a child under sixteen of whom he has "custody," "charge" or "care." The act presumes that a child is in the custody of its parents, step-parents, or a person cohabiting with its parent, or of its guardians or persons liable by law to maintain it; that it is in the charge of a person to whom the parent has committed such charge (e.g. a schoolmaster), and that it is in the care of a person who has actual possession or control of it. Cruelty is defined as consisting in assault, ill-treatment (falling short of actual assault), neglect, abandonment or exposure of the child in a manner likely to cause unnecessary suffering or injury to health, including injury to or loss of sight, hearing or limb, or any organ of the body or any mental derangement; and the act or omission must be wilful, i.e. deliberate and intentional, and not merely accidental or inadvertent. The offence may be punished either summarily or on indictment, and the offender may be sent to penal servitude if it is shown that he was directly or indirectly interested in any sum of money payable on the death of the child, e.g. by having taken out a policy permitted under the Friendly Societies Acts. A parent or other person legally liable to maintain a child or young person shall be deemed to have "neglected" him, if, by failing to provide adequate food, clothing, medical aid, or lodging, or if in the event of inability to provide such food, &c., by failure to take steps to procure the same under acts relating to the relief of the poor.

These statutes overlap the common law and the statutes already mentioned. Their real efficacy lies in the main in the provisions which facilitate the taking of evidence of young children, in permitting poor law authorities to prosecute at the expense of the rates, and in permitting a constable on arresting the offender to take the child away from the accused, and the court of trial on conviction to transfer the custody of the child from the offender to some fit and willing person, including any society or body corporate established for the reception of poor children or for the prevention of cruelty to children. The provisions of the acts as to procedure and custody extend not only to the offence of cruelty but also to all offences involving bodily injury to a child under sixteen, such as abandonment, assault, kidnapping and illegally engaging a child in a dangerous public
The act of 1908 also makes an endeavour to check the heavy mortality of infants through "overlaying," enacting that where it is proved that the death of an infant under three years of age was caused by suffocation whilst the infant was in bed with some other person over the age of sixteen, and that that person was at the time of going to bed under the influence of drink, that other person shall be deemed to have neglected the child in manner likely to cause injury to its health, as mentioned above. The acts have been utilized with great zeal and on the whole with much discretion by various philanthropic societies, whose members make it their business to discover the ill-treated and neglected children of all classes in society, and particularly by the Society for the Prevention of Cruelty to Children, which is incorporated under royal charter of the 28th of May 1893, for the purposes inter alia of preventing the public and private wrongs of children, and the corruption of their morals and of taking action to enforce the laws for their protection.

The act of 1908 enacted more stringent provisions against baby-farming (q.v.). The Infant Life Protection Act of 1897 did not apply where only one child was taken, but now by the act of 1908, where a person undertakes for reward the nursing and maintenance of one or more infants under the age of seven years apart from their parents or having no parents, must give written notice to the local authority within forty-eight hours from the reception of the child. If an infant is already in the care of a person without reward and he undertakes to continue the nursing for reward, such undertaking is a reception of the child. The notice to the local authority must state the name, sex, date and place of birth of the infant, the name and address of the person receiving the infant and of the person from whom the infant was received. Notice must also be given of any change of address of the person having the care of the infant, or of the death of the infant, or of its removal to the care of some other person, whose name and address must also be given. It is the duty of local authorities to provide for the carrying-out in their districts of that portion of the act which refers to nursing and maintenance of infants, to appoint infants' protection visitors, to fix the number of infants which any person may retain for nursing, to remove infants improperly kept, &c. Relatives or legal guardians of an infant who undertake its nursing and maintenance, hospitals, convalescent homes, or institutions, established for the protection and care of infants, and conducted in good faith for charitable purposes, as well as infant schools at which efficient elementary education is given, are exempt from the provisions of the act.

The acts of 1904 and 1908 deal with many other offences in relation to children and young persons. The act of 1904 introduced restrictions on the employment of children which lie on the border line between cruelty and the regulation of child labour. It prohibits custodians of children from taking them, or letting them be, in the street or in public-houses to sing, play, perform or sell between 9 P.M. and 6 A.M. These provisions apply to boys under fourteen and girls under sixteen. There are further prohibitions (1) on allowing children under eleven to sing, play, perform or be exhibited for profit, or offer anything for sale in public-houses or places of public amusement at any hour without a licence from a justice, which is granted only as to children over ten and under stringent conditions; (2) on allowing children under sixteen to be trained as acrobats, contortionists, or circus performers, or for any dangerous performance; and the Children's Dangerous Performances Act 1879, as amended in 1897, makes it an offence to employ a male young person under sixteen and a female under eighteen in a dangerous public performance.

The act of 1908 renders liable to a fine not exceeding £25, or alternatively, or in addition thereto, imprisonment with or without hard labour for any term not exceeding three months, any custodian, &c., of any child or young person who allows him to be in any street, premises or place for the purpose of begging or receiving alms, or of inducing the giving of alms, whether or not there is a pretence of singing, playing, performing or offering anything for sale. An important departure in the act of 1908 was the attempt to prevent the exposure of children to the risk of burning. Any custodian, &c., of a child under seven who allows that child to be in a room containing an open grate not sufficiently protected to guard against the risk of burning or scalding is liable on summary conviction to a fine not exceeding £10. Provision is made against allowing children between the ages of four and sixteen to be in brothels; it is also made a misdemeanour if any custodian, &c., of a girl under sixteen causes or encourages her seduction or prostitution, and any person having the custody of a young girl may be bound over to exercise proper care if it is shown to the satisfaction of the court of summary jurisdiction, on the complaint of any person, that she is exposed to any risk.

The act of 1908, following legislation in many parts of the United States and in some of the British colonies, places a penalty on selling tobacco to any person apparently under the age of sixteen, whether for his own use or not. It empowers constables and park keepers to seize tobacco in the possession of any person apparently under sixteen found smoking in any street or public place, as well as to search them; it also empowers a court of summary jurisdiction to prevent automatic machines for the sale of tobacco being used by young persons. The act also contains useful provisions empowering the clearing of a court whilst a child or young person is giving evidence in certain cases (e.g. of decency or morality), and the forbidding children (other than infants in arms) being present in court during the trial of other persons; it places a penalty on pawnbrokers taking an article in pawn from children under fourteen; and on vagrants for preventing children above the age of five receiving education.

It puts a penalty on giving intoxicating liquor to any child under the age of five, except upon the orders of a duly qualified medical practitioner, or in case of sickness, or other urgent case, at the request of the holder of the licence, or any licensed premises who allows a child to be at any time in the bar of the licensed premises, or upon any person who causes or attempts to cause a child to be in the bar of licensed premises other than railway refreshment rooms or premises used for any purpose to which the holding of a licence is merely auxiliary, or where the child is there simply for the purpose of passing through to some other part of the premises. It makes provision for the safety of children at entertainments, and consolidates the law relating to reformatory and industrial schools, and to juvenile offenders (see Juvenile Offenders).

In the act of 1908, "child" is defined as a person under the age of fourteen years, and "young person" as a person who is fourteen years and upwards and under the age of sixteen years. The act applies to Scotland and Ireland. In the application of the act to Ireland exception is made relative to the exclusion of children from bars of licensed premises, in the case of a child being on licensed premises where a substantial part of the business carried on is a drapery, grocery, hardware or other business wholly unconnected with the sale of intoxicating liquor, and the child is there for the purpose of purchasing goods other than intoxicating liquor.

British Possessions.—Legislation much on the lines of the acts of 1895-1906 has been passed in many British possessions, e.g. Tasmania (1895, 1906), Queensland (1896, 1905), Jamaica (1896), South Australia (1890, 1904), New South Wales (1892 and 1900), New Zealand (1906), Mauritius (1906), Victoria
CHILDRENITE—CHILDREN’S COURTS

(1905, 1906). In South Australia a State Children’s Department has been created to care for and manage the property and persons of destitute and neglected children, and the officials of the council may act in cases of cruelty to children; the legislation of Victoria and Queensland is based on that of South Australia. See also Children’s Courts, Education and Labour Legislation. (W. F. C.; T. A. I.)

CHILDRENITE, a rare mineral species; a hydrous basic aluminium iron phosphate, orthorhombic in crystallization. The ferrous oxide is in part replaced by manganous oxide and lime, and in the closely allied and isomorphous species eosphorite manganese predominates over iron. The general formula for the two species is Al(Fe, Mn)(OH)PO₄·H₂O. Childrenite is found only as small brilliant crystals of a yellowish-brown colour, somewhat resembling chalcybite in general appearance. They are usually pyramidal in habit, often having the form of double six-sided pyramids with the triangular faces deeply striated parallel to their shorter edges. Hardness 4-5-5; specific gravity 3-18-3-24. The mineral, named after the zoologist and mineralogist J. G. Children (1777–1828), secretary of the Royal Society, was detected in 1823 on specimens obtained some years previously during chartering a canal near Tavistock in Devonshire. It has also been found in a few copper mines in Cornwall and Devonshire.

Eosphorite occurs as crystals of prismatic habit with angles very nearly the same as those of childrenite. Unlike childrenite, it has a distinct cleavage in one direction, and often occurs in compact masses as well as in crystals. The colour is sometimes yellowish-white, but usually rose-pink, and on this account the mineral was named from ἐσοφόρος, dawn-bearer. Hardness 5; specific gravity 3-11-3-145. It was discovered in 1878 in a pegmatite-vein at Branchville, Connecticut, where it is associated with other rare manganese phosphates. (L. J. S.)

CHILDREN’S COURTS, or Juvenile Courts, a special system of tribunals for dealing with juvenile offenders, first suggested in the United States. The germ of such institutions was planted in Massachusetts in 1869, when a plan was introduced at Boston of hearing charges against children separately, and apart from the ordinary business of the lesser tribunals. No great progress was made in the development of the idea in Massachusetts, the legal authorities were not fully convinced of the utility or need for a separate court so long as the children were kept strictly apart from adults, and this could be assured by a separate session. But the system of “probation,” by which children were handed over to the kindly care and guardianship of an appointed officer, and thus escaped legal repression, was created about the same time in Boston and produced excellent results. The probation officer is present at the judge’s side when he decides a case, and is given charge of the offender, whom he takes by the hand, either at his parent’s residence or at school, and continually supervises, having power if necessary to bring him again before the judge. The example of Massachusetts in due course influenced other countries, and especially the British colony of South Australia, where a State Children’s Department was created at Adelaide in 1895, and three years later a juvenile court was opened there for the trial of persons under eighteen and was conducted with great success, though the system of probation officers was not introduced. A juvenile court was also established at Toronto (Canada) on the South Australian model.

The movement when once fully appreciated went ahead very rapidly. In the United States Illinois was the first state to call a distinct children’s court into existence, and Judge Richard Tuthill was the pioneer at Chicago, where the court was established in 1895. Many states followed suit, including New York, Pennsylvania, Rhode Island, Wisconsin, Kansas, Colorado, Indiana and others, till the number rose to nineteen in 1906. In New York, where juvenile probation is supervised by the Society for the Protection of Children, there is a separate children’s court with rooms attached, where the children for detention wait till they are brought in for trial. Brooklyn has also a children’s court. In Pennsylvania, where the juvenile court was at first opposed as unconstitutional, the difficulty was met by first bringing the child before the magistrate in the police court, a course which (though followed by his transferring the case to the special court) perpetuated the very evils the children’s court was intended to avoid; the work of probation was, however, most effectively carried out, chiefly by female officers. The Chicago Juvenile Court sits twice weekly under an especially appointed judge, and policemen act as probation officers to some extent. The court of Indianapolis, however, gained the reputation of being the most complete and perfect in the United States. It works with a large and highly efficient band of volunteer probation officers under a chief. The juvenile court of Denver, Colorado, attained remarkable results under Judge B. Lindsey, whose magnetic personality, wonderful comprehension of boy nature, and extraordinary influence over them achieved great results. The court meets once a fortnight, when fresh cases are tried and boys already on probation report themselves, often to the number of two hundred at a time. The latter appear before the judge in batches, each hands in his school report in a sealed letter, and according to its purport receives praise or blame, or he may be committed to the Detention House. An afterthought in 1898 was to constitute at New York, and later, with a judge especially chosen, a presiding probation being for fixed periods, varying from three months to three years, and children being brought back to the court for parole or discharge, or, if necessary, committal to the house of one of the philanthropic societies. In Washington, D.C., the system of having no distinct court or judge, but holding a separate session, was followed, and it was found that numbers of children came to the court for help and guidance, looking upon the judge for the time being as their friend and counsellor. Probation in this instance offered peculiar difficulties on account of the colour question, two-thirds of the children having negro blood and a white boy being always preferred for a vacant situation. Throughout, the action of juvenile courts in the United States has been to bring each individual into “human touch” with kindly helpful workers striving to lead the young idea aright and train it to follow the straight path. It was the result always of the effort of private persons and not due to government initiative, indeed the advocates and champions of the system only established it by their efforts and influence.

Progress in the same direction has been made in England. The home office had recommended London police magistrates to keep children’s cases separate from those of adults; the same practice or something analogous obtained in many county boroughs, such as Bath, Birmingham, Bristol, Bolton, Bradford, Hull, Manchester, Walsall, Halifax and others, and the Children Act 1908 definitely established children’s courts. This act enacted that courts of summary jurisdiction when hearing charges, &c., against children or young persons should, unless the child or young person is charged jointly with an adult, sit in a different building or room from that in which the ordinary sittings of the court are held, or on different days or at different times. Furthermore, provision must be made for preventing persons apparently under the age of sixteen years whilst being conveyed to or from court, or whilst waiting before or after their attendance in court, from associating with adults, unless such adults are charged jointly with them. The act prohibits any persons other than members and officers of the court, the parties to the case, their solicitors, counsel and other persons directly concerned in the case, from being present in a juvenile court, except by leave of the court. Bona-fide press representatives are also excepted. The main object of the whole system is to keep the child, the embroicter offender who has probably erred from ignorance or the pressure of circumstances or misfortune, altogether free from the taint or contagion that attaches to criminal proceedings. The moral atmosphere of a legal tribunal is injurious to the youthful mind, and children who appear before a bench, whether as accused or as witness, gain a contemptuous familiarity with legal processes.

The most beneficial action of the children’s court comes from its association with the system of personal guardianship and
CHILDREN'S GAMES—CHILDS

Singing games are danced principally in one of two methods, "line" and "circle." These represent two of the early forms of dramatic action. The "line" form (two lines of players standing opposite each other having a space of ground between them, advancing and retiring in turn) represents two different and opposing parties engaged in a struggle or contest. This method is used in all cases where contest is involved. The "circle" form, on the other hand, where all players join hands, represents those occasions when all the people of one place were engaged in celebrating events in which all were interested. Thus games celebrating sowing and harvest, and those associated with love and marriage, are played in this form. Both these methods allow of development. The circle varies from examples where all perform the same actions and say the same words to that where two or more players have principal parts, the others only singing or acting in dumb show, to examples where the singing has disappeared. The form or method of play and the actions constitute the oldest remaining parts of the game (the words being subject to alterations and loss through ignorance of their meaning), and it is to this form or method, the actions and the accompaniment of song, that they owe their survival, appealing as they do to the strong dramatic instinct of children and of uncultured folk.

To be competent to give a few instances of the best-known singing games. In "line" form, a fighting game is "We are the Rovers." The words tell us of two opposing parties fighting for their land; both sides alternately deride one another and end by fighting until one side is victorious. Two other "line" games, "Nuts in May," and "Here come three drakes a-riding," are also games of contest, but not for territory. These show an early custom of obtaining wives. They represent marriage by capture, and are played in "line" form because of the element of contest contained in the custom. Another form, the "arch," is also used to indicate contest.

Circle games, on the contrary, show such customs as harvest and marriage, with love and courting, and a ceremony and sanction by assembled friends. "Oats and beans and barley" and "Sally Water" are typical of this form. The large majority of circle games deal with love or marriage and domestic life. The customs surviving in these games deal with tribal life and take us back to "foundation sacrifice," "well worship," "sacredness of fire," besides marriage and funeral.

Details may be found in the publications of the Folk-Lore Society, and particularly in the following works:—A. B. Gomme's Traditional Games of Great Britain (2 vols., Nurt, 1894-1898); Gomme's Child's Singing Games (Nurt, 1901); Eckenstein's Comparative Studies in English Folk-songs (1906); Macclagan, Games of Arrangement (1900); Newell's Games of American Children (Harper Bros., New York, 1884).

In Mrs Gomme's Traditional Games, several versions of each game, together with a short account of the suggested origin and of the custom or belief indicated, are given for each game. In vol. ii. (pp. 458-531) a memoir of the history of games is given, and the customs and beliefs which originated them, reviewing the whole subject from the anthropological point of view, and showing the place which games have in the social and mental life of early man. In Miss Eckenstein's comparative study of nursery rhymes suggested origins are given for many of these, and an attempt made to localize certain of the customs and events. In several of the publications of the Folk-Lore Society, collections of nursery rhymes are given, all of which may be studied with advantage.Stubbs and other early writers give many instances of boys' games in their days, many of which still exist. Tylor and other writers on anthropology, in dealing with savage custom, confirm the views here expressed. For nursery rhymes see Halliwell, Nursery Rhymes (1845), and Chambers's Popular Rhymes (first printed 1841, reprinted in 1870). The recently collected Morris Dances by Mr Cecil Sharp should also be consulted. The game of 'Ploughing and Planting' is danced in circle form, while others indicating fighting or rivalry are danced in line form, each line dancing in circle before crossing over to the opposite side, and thus conforming to the laws already shown to exist in the maternal games. (A. B. G.)

CHILDS, GEORGE WILLIAM (1829-1894), American publisher, was born in Baltimore, Maryland, on the 12th of May 1829. He was educated in the public schools, and after a brief term of service in the navy, he became in 1843 a clerk in a book-shop at Philadelphia. There, in 1847, he established an independent
book-shop, and two years later organized the publishing house of Childs & Peterson. In 1864, with Anthony J. Drexel, he purchased the Public Ledger, at that time a little-known newspaper; he completely changed its policy and methods, and made it one of the most influential journals in the country. He died at Philadelphia on the 3rd of February 1894. Childs was widely known for his public spirit and philanthropy. In addition to numerous private benefactions in educational and charitable fields, he erected memorial windows to William Cowper and George Herbert in Westminster Abbey (1877), and to Milton in St. Margaret's, Westminster (1888), a monument to Leigh Hunt at Kensal Green, a Shakespeare memorial fountain at Stratford-on-Avon (1887), and monuments to Edgar Allan Poe and to Richard A. Proctor. He gave Woodland Cemetery to the Typographical Society of Philadelphia for a printers' burial-ground, and with Anthony J. Drexel founded in 1892 a home for Union printers at Colorado Springs, Colorado.

His Recollections were published at Philadelphia in 1890.

CHILE, or Chili (derived, it is said, from the Quichua chiri, cold, or icchil, snow), a republic of South America, occupying the narrow western strip of the continent, from the mouth of the Arica, on the north, to the Strait of Magellan, on the south. The country is mountainous, with few alluvial plains, and is covered with scattered forests. The Andes, rising more than 20,000 feet above the sea, dominate the landscape. The country is divided into the following provinces: Coquimbo, Atacama, Tarapacá, Antofagasta, La Serena, Coquimbo, La Araucanía, Biobío, Los Ríos, Los Lagos, and Magallanes.

The physical geography of Chile is dominated by the Andes, which run parallel to the coast and divide the country into a series of narrow, elongated, and irregular valleys. The coastal strip is narrow and barren, with a few scattered alluvial plains. The interior is divided into the Patagonian desert, the Atacama desert, and the Oriental highlands. The Patagonian desert is the driest region in the world, with an annual precipitation of less than 50 mm. The Atacama desert is the driest desert in the world, with an annual precipitation of less than 1 mm. The Oriental highlands are the most productive region of the country, with a Mediterranean climate and fertile plains.

The major rivers of Chile include the Maipo, Aconcagua, and Biobío. The Maipo River is the largest river in Chile and is used for irrigation. The Aconcagua River is the source of the River Plate, which flows into the South Atlantic Ocean. The Biobío River is the longest river in Chile and is used for irrigation and hydroelectric power.

The official languages in Chile are Spanish and Quechua. The population of Chile is about 19 million, of which about 70% are of European descent, 20% are mestizos, and 10% are native peoples. The capital of Chile is Santiago, which is located in the Metropolitan Region, the most populated region of the country.

Chile is a federal republic, with a presidential system of government. The President is elected for a term of four years. The country is divided into 16 provinces, which are further divided into 79 comunas and 1,062 municipalities. The country has a mixed economy, with a strong emphasis on agriculture, mining, and forestry.

Chile is a signatory to the United Nations and the Organization of American States. The country has a left-wing political tradition, with the Socialist Party being the largest political party.

The main exports of Chile include copper, coal, and fertilizers. The country has a significant fishing industry, with anchovies and hake being the main catches. The country also has significant hydroelectric power generation, with the majority of its energy generated from hydroelectric power.

Chile is a member of the Mercosur trade bloc and has a free trade agreement with the United States. The country is also a member of the Andean Community of Nations (CAN) and the South American Customs Union (SUATE). The country has a significant tourism industry and is a popular destination for both domestic and international tourists.
it is known as the Cordillera Silillica, and then following the trend of the coast north-westward into Peru becomes the Cordillera Occidental. The western slopes of the Andes are precipitous, with short spurs enclosing deep valleys. The whole system is volcanic, and in many places is rendered subject to earthquakes and other geological phenomena of the same class. Chile is now remarkably active, noticeably in central and southern Chile. The culminating point of the Chilean Andes is Aconcagua, which rises to a height of 23,097 ft.

In southern Chile the coast is highly mountainous, but the relation of these elevations to the Andes has not been clearly determined. The highest of these apparently detached groups are Mt. Macá (lat. 45° 45' S.), 9717 ft., and Mt. Arenales (about 47° 3', lat.), 11,286 ft. Cathedral Peak on Wellington Island rises to a height of 3938 ft. and is the highest point on the entire coast of the Pacific. More than a thousand smaller peaks and ridges are scattered over the Andes from the Andes to the coast, forming transverse valleys of great beauty and fertility. The most famous of these is the "Vale of Quillota" between Valparaiso and Santiago. The Chileans believe that this vale was levelled by a large earthquake, and that at elevations exceeding 10,000 ft. The best-known of these is the Uspallata pass between Santiago and the Argentine city of Mendoza, 12,870 ft. above sea-level. The passes of central and south Chile are only open in the winter season, but those of northern Chile are open throughout the year.

The volcanic origin of the Andes and their comparatively recent elevation still subject Chile, in common with other parts of the western coast, to frequent and sometimes violent earthquakes. In some instances where European occupation, violent earthquake shocks have resulted in considerable elevations of certain parts of the coast. After the great earthquake of 1835 Captain Robert Fitz-Roy, commanding H.M.S. Beagle, collected and published a detailed survey of this region was made by English naval officers; the charts prepared from their surveys are still in use and form the basis of all subsequent maps. None of these islands is inhabited, but some of the smaller ones afford fine harbours. One of the most remarkable movements is the formation of the Island of Quellon, off the coast of Chiloé and about 300 miles north of the south of Chile.

None of these islands is inhabited, but some of the smaller ones afford fine harbours. One of the most remarkable movements is the formation of the Island of Quellon, off the coast of Chiloé and about 300 miles north of the south of Chile.
The Bay of San Carlos on the northern coast of Chile, which opens upon the narrow Chacao channel, has the port of Ancud, or San Carlos, and is rated an excellent harbour for vessels of light and medium draught. Inside the island of Chiloé there are several harbours rated for boats of moderate draught. In the north end of the first is the Reloncavi, a large and nearly landlocked bay, on which stands Puerto Montt, the southern terminus of the Chilean central railway. The large Gulf of Peñas, south of Taltal, is entered by a long and narrow channel, and the last and farthest inland of its arms is Last Hope Inlet (Ultima Esperanza), on which is situated the Chilean agricultural colony of Puerto Cisnes. The Straits of Magellan, about 360 m. in length, lie wholly within Chilean territory. Midway of them is situated Punta Arenas, the most southern town and port of the republic.

Except in the extreme south the hydrography of Chile is of the simplest description, all the larger rivers having their sources in the Andes. The river courses are necessarily short, and only a few have navigable channels, the aggregate length of which is only 750 m. Nearly all rivers in the desert region are lost in the sands long before reaching the sea. Some rivers, however, are navigable for a distance of a time when climatological conditions on this coast were different. The principal rivers of this region are Sama (which forms the provisional boundary line with Peru), Tacna, Camarones, Lea, Coquimbo, Huasco, and Limari, all of which are navigable. The largest, having its sources on the slopes of the Cordillera south of the Minho volcano, between 21° and 23° 30' S., and flowing south on an elevated plateau to Chiu-Chiu, and thence west and north, is a great curve to Quillauna, whence its dry channel flows westward again and reaches the Pacific in 21° 28' S., a few miles south of the small port of Huarillos. Its total length is estimated at 295 m., the width of the river at its mouth being 800 yds above the sea and receiving a large volume of water from the Cordilleras. The water of its upper course and tributaries is sweet, and is conducted across the desert in pipes to some of the coast towns, but in winter snow courses, as in all the rivers of this region, become brackish. The Copiapó, which once discharged into the sea, is now practically exhausted in irrigating a small fertile valley in which stands the city of that name. The Copiapó and Huasco have comparable courses, but their waters are from the higher sierras. The latter is also used to irrigate a small, cultivated valley. The rivers of the province of Coquimbo—the Elqui or Coquimbo, Limari and Choapa—exist under less arid conditions, and discharge into the Pacific. The region of Aconcagua and Lampa are used to irrigate a much larger area of cultivated territory. The central agricultural provinces are traversed by several important rivers, all of them rising on the western slopes of the Andes, and, after breaking through the coast range, discharge into the Pacific after being extensively used to irrigate the great central valley of Chile. These are the Maipo (Maypo or Maipú), Rapel, Mataquito, Maule, Itata, Bio-Bio, Imperial, Tolten, Valdivia, or the Bi-Bi, Bueno and Maullin. With the exception of the first three, these rivers have short navigable channels, but they are open only to vessels of light draught because of sand-bars at their mouths. The largest is the Bio-Bio, which has a total length of 220 m., 100 of which is navigable. The river, throughout its course, has been improved by artificial development of this part of Chile, affording means of transportation where railways and highways were entirely lacking. Some of the larger tributaries of these rivers, whose economic value has been increased by irrigation, flow into the province of Santiago and enters the Maipo from the north; the turbulent Cachapoal, which joins the Rapel from the north; the Clarío, which waters an extensive part of the province of Talca and enters the Maipo from the north; and the Nuble, which is the largest river of the north of the peaks of Chiloe and flows entirely across the province of Nuble to join the Itata on its western frontier; the Laja, which rises in a lake of the same name near the Argentine frontier in about lat. 35° 30' S., which forms an important river, and which is the principal source of the Imperial. The unsettled southern regions of the country contain many important rivers which have been only partially explored. They have their sources in the Andes, some of them on the eastern side of the line of highest summits. The Puelo has its origin in a lake of the same name near the western coast of Guaiteca Island, and flows north-west through the Cordilleras into an estuary (Reloncavi Inlet) of the Gulf of Reloncavi at the northern end of the Gulf of Chacao. Its lower course is impeded in such a manner as to form three small lakes, called Superior, Inferior and Taguatagua. A large northern tributary of the Puelo, the Manso, has its sources in Lake Mascarí and other lakes and streams south-east of the Cerro Tronador, also in Argentina. This river, whose source is lost on the coast near 36° 7' S., flares with the Puelo a few miles west of the 72nd meridian. The Reloncavi Inlet also receives the outflow of Lake Todos los Santos through a short tortuous stream called the Petroleu. The Comau Inlet and river are joined by the small streams of the region, which come from the range and Chiloé, and traverse a densely wooded country in a north-west direction from the lands to the north-east shore of the Gulf of Chacao. Continuing southward, the Yelcho is the next important river. This stream drains all the country above the estuary, a large area of Argentine territory, where it is called the Rio Fetalofu or Fetaluaque, its principal source being a large lake of the same name. It flows south-west through the Andes, and then north-west through Lake Yelcho, the principal source of which is the Lake General Carrera. After the month of October, settled principally by Welshmen from Chubut, is located on some of the upper tributaries of this river, in about lat. 43° 5' S. The Palena is another river of the same character, having its source in a lake extending from the province of Cañadón, and flowing almost through Argentine territory before crossing into Chile. It receives one large tributary from the south, the Rio Pico, and enters an estuary of the Gulf of Cordovado a little north of the 44th parallel. The Frías is wholly a Chilean river, draining an extensive Andean region between the 44th and 45th parallels and discharging into the Bajo Magallanes, which separates Magdalena island from the mainland. The Aisen also has its source in Argentinn territory, and discharges into the Gulf of Cook, which lies far north as the 45th parallel, receiving numerous tributaries, and discharging a large volume of water into the Moraleda channel in about lat. 45° 20' S. The lower course of this river is essentially an estuary, while at its mouth lies a group of smaller islands, called Baker Archipelago, which separate it from Messier Channel. The course of the Las Heras from Lake Buenos Aires is south and south-west, the short range of mountains in this area are the Andes, San Valentín and Arenales forcing it southward for an outlet. Baker Inlet also receives the waters of still another large Argentine-Chilean lake, San Martín, whose far-reaching fjord-like arms extend from lat. 49° to 48° S.; its head is dammed by a dam discharges into the Tero, or La Pascua, river. Lake San Martín lies in a crooked deeply cut passage through the Andes, and the divide between its southern extremity (Laguna Tar) and Lake Viedma, which discharges through the small Cuernos Channel into the Atlantic, is said to be the most spectacular on the earth. It is believed that this is the most beautiful strait between the two oceans.

Nearly all fjords and connecting channels terminating inland in a peculiarly shapely body of water are navigable, and there are a number of large estuaries, a phenomenon not to be found elsewhere in the same latitudes.

The lakes of Chile are numerous and important; but they are for the most part found in the southern and central regions. The only lakes are large lagoons, or morasses, on the upper saline plateaus between the 25th and 28th parallels. After they are fed from the melting snows and stormy waters of the eastern Andes, many of their streams flow into the Pacific. Their waters are saturated with saline compounds, which in some cases have considerable commercial value. In central Chile above the Bio-Bio river the lakes are small and have no special geographical relations. The most important are the Llanquihue, near Puerto Montt, in about lat. 36° 7' S., and Laguna de la Laja, in 37° 20', which lie in the Andes near the Argentine frontier and are sources of two rivers of the same names. Below the Bio-Bio river there is a line of large picturesque lakes, each with its source on the eastern side of the Andes and emptying into the Pacific; the one southward, the Llanquihue, corresponding in character and position to the dry lacustrine depressions extending northward in the same valley.
CHILE

They lie on the eastern side near the Cordilleras, and serve the purpose of great reservoirs for the excessive precipitation of rain and snow on their western slopes. With one exception they all drain westward into the Pacific through short and partly navigable rivers, and some of the lakes are also utilized for steam navigation. These are the principal reservoirs of the southern extreme of Cauca, Rinhué and Rancagua and Valdivia, and Puychue, Rupanco, Lanhuqiu and Todos los Santos in Llanquihue. The largest of the number is Lakes Rancano and Lanquaihue, the former with an estimated area of 200 sq. m., and the latter with 250 sq. m., and 350 ft. above sea-level. The great Andean lakes of Llanquihue, the latter with an estimated area of 402 sq. m. in 1887), and the former with 426 sq. m., and 250 ft. above sea-level. The great Andean lakes of Puyeredon, or Cochran (47° 15'), and San Martin (49° S.), lie partly within the Chilean territory. In the extreme south are Lagoa Blanca, a large fresh-water lake in lat. 52° 30', and two large inland salt-water lakes, known as Otway Water and Skyrwater, connected by Fire-Percy Pass.

Geology.—Chile may be divided longitudinally into two regions which differ from each other in their geological structure. Along the coast lies a belt of granite and schist overlain unconformably by the strata of the Jurassic and Cretaceous, which in turn are unconformably covered by the strata of the Tertiary and Quaternary. The mountains are generally composed of folded Mesozoic beds, together with volcanic rocks of later date. The great longitudinal valley of Chile runs approximately, but only approximately, along the boundary between the two zones, the coast to the north and the Cordilleras to the south, the sea and the Andean zone reaches to the shore. The strata which form the most characteristic feature of the former do indeed occur upon the coast of Peru, but in the north of Chile they form an essentially different series of strata, and the second stratum is represented by that of the later period. They are known to be of late Jurassic, but whether they be Palaeozoic or Archæan is uncertain. They are strongly folded and are overlaid unconformably by Cretaceous and Tertiary deposits. In the north, south, and west, the Tertiary deposits are represented by those of later date, but towards the south, the Mesozoic beds, which are at least part of Cretaceous, form a band of considerable width. The Tertiary beds include both marine and terrestrial deposits, and appear to be of Mixed of Maestrichtian age.

The Andes of Tierra del Fuego are occupied by plateaus of horizontal Tertiary strata.

The Chilean Andes correspond with the Western Cordillera of Bolivia and Peru, and consist almost entirely of Jurassic and Cretaceous strata, with a very slight development of Tertiary strata. The Mesozoic beds are thrown into a series of parallel folds which run in the direction of the chain and which are generally free from any complications such as overthrusting or overfolding. The Cretaceous beds form a synclinal upon the eastern side of the chain (and, in general, towards the sea), and the strata of the latter are thrown into a number of folds which form the axis and the regional flank.

Through the Mesozoic beds are intruded granite and other igneous rocks of Tertiary age, and upon the folded Mesozoic formation, in the highlands of the Andes, is laid the sedimentary deposits of Tertiary age, which are represented only at La Ternera near Copiapó, where coal-seams with Rhætic plants have been found; but the rest of the Mesozoic, without the limit to the Upper Cretaceous, appears to have been represented by deposits of a more siliceous type, which are certainly volcanic, and as they contain marine fossils they must have been laid down beneath the sea. They are not confined to any one horizon, but occur irregularly throughout the Jurassic and occasionally through the Cretaceous series, and form continuous beds, which are characterized by certain forms of fossils which are very common in the Mesozoic beds of the same age. The fauna of the Mesozoic beds is very rich, and includes forms which are found in northern Europe, others which occur in central Europe, and others again which are characteristic of southern Europe. The Tertiary succession of the Andes is represented by the fauna of Neumayer's theory of climatic zones. A large part of the chain is covered by the products of the great volcanoes which still form the highest summits of the Chilean and Argentine Andes. The rocks are largely composed of andesite and basalt, and the andesites are lavas of the still active volcanoes of the south are olivine-bearing hypersthenes-andesite and basalt.  

Climate.—The climate of Chile varies widely, from the tropical heat and extreme arid conditions of the northern coast to the low temperatures and extreme humidity of western Tierra del Fuego and the southern coast. The high altitudes of the Andean region also introduce vertical zones of temperature, modified to some extent by the rainless plateaus of the north, and by the excessive rainfall of the south. In general it may be said that the extreme temperature are not so great as in corresponding latitudes of the northern hemisphere, because of the greater expanse of water in comparison with the land areas, the summers being cooler and the winters warmer than in the same latitudes of the northern hemisphere. The extreme temperature is higher in the north than in the south, and the most extreme are found in the eastern Andes, where the easterly moisture-laden winds from the Atlantic to so high an elevation that they sweep across Chile without leaving a drop of rain. At very rare intervals light rains fall in the desert regions north of the line of the Cordillera and mostly caused by the prevailing coast winds. With this exception these regions are barren and the country is dry. The arid lands are characterized by a great number of lagoons, the principal of which is the Lagoa Verde, the largest of which is the Lagoa Pampa, the latter with an estimated area of 402 sq. m., and 250 ft. above sea-level. The great Andean lakes of Puyeredon, or Cochran (47° 15'), and San Martin (49° S.), lie partly within the Chilean territory. In the extreme south are Lagoa Blanca, a large fresh-water lake in lat. 52° 30', and two large inland salt-water lakes, known as Otway Water and Skyrwater, connected by Fire-Percy Pass.

...
its division into at least three general zones—the desert provinces of the north, central Chile, and the humid regions of the south. The first is an arid desert absolutely barren along part of the coast, between Tacna and Copiapó, but with a coarse scanty vegetation near the Cordilleras along watercourses and on the slopes where moisture from the melting snows above percolates through the sand. In the valleys of the Copiapó and Huasco rivers a meager vegetation is to be found near their channels, apart from what is produced by irrigation, but the surface of the plain is bare. Thistles and a few coarse grasses (Guevina), and only then the shrub, to be found on the coast is a species of Skytanthus. Near the sierras where irrigation is possible, fruit growing is so successful, especially the grape and fig, that the product is considered the best in Chile. In regard to the indigenous flora of this region John Ball says: "The species which grow here are the more or less modified representatives of plants which at some former period existed under very different conditions of life. Proceeding southward, the climate becomes warmer, thus a larger number of genera and species peculiarly its own. A large majority of the 198 genera peculiar to the South American temperate regions belong exclusively to central Chile, this zone extends from about the 30th to the 36th parallel, perhaps the region of most characteristic vegetation. The evergreens largely predominate here as well as in the extreme south and on the open, sunburnt plains the vegetation takes on a more tropical aspect. One of the most characteristic trees of this zone is the avocado (Persea americana), a native of tropical America, found throughout the central provinces along the coast and far to the south as the transverse ranges of mountains across the province of Aconcagua.

To some degree the flora of central Chile is of a transition character between the northern and southern provinces, which is evidenced by the large number of genera and species peculiarly its own. A large majority of the 198 genera peculiar to the South American temperate regions belong exclusively to central Chile, this zone extends from about the 30th to the 36th parallel, perhaps the region of most characteristic vegetation. The evergreens largely predominate here as well as in the extreme south and on the open, sunburnt plains the vegetation takes on a more tropical aspect. One of the most characteristic trees of this zone is the avocado (Persea americana), a native of tropical America, found throughout the central provinces along the coast and far to the south as the transverse ranges of mountains across the province of Aconcagua.

Several exotic species have been introduced into this part of Chile, some of which have thriven even better than in their native habitats. Among these are the oak, elm, beech (Nothofagus), walnut, chestnut, poplar, willow and eucalyptus. Through the central zone the plains are open and there are forests on the mountain slopes, but in the southern zone there are no plains, with the exception of small areas near the Straits of Magellan, and the forests are under a large number of genera and species peculiarly its own. The native elements of the family of the exotics remind one of the tropics. They are made up, in great part, of the evergreen beech (Fagus betuloides), the deciduous antarctic beech (F. antarctica), and Winter's bark (Drimys winteri), the deciduous trees willow and white dogwood (Cornus). The deciduous shrubs and plants, among which are the Myrtus, myrtle and its various species, Juniperus rigida, Myrtus mammillaria, two or three species of Berberis, wild currant (Ribes antarcticum), a trailing blackberry, tree ferns, reed-like grasses growing wild in Chile, and the beautiful Cordillera, in the extreme south, the climate is drier and open, and grassy plains are found, but on the western side the drier forests extend from an altitude of 1000 to 1500 ft. down to the level of the sea, and their distribution is determined by the growing season. These forests are remarkable for their variety and richness of forms, as is a small globular fungus growing on the bark of the beech, which is a staple article of food among the Fuegians—probably the only instance where a fungus is a bread of the people.

There is generally conceded that the vegetation in southern Chile, in general, forms a very important link in the flora of Chile and neighbouring islands and on the adjacent mainland. The strawberry is also indigenous to these latitudes on both sides of the Andes, and Chile is credited with a species from which the cultivated strawberry derives some of its best qualities. Maize and quinua (Chenopodium quinoa) were known in Chile before the arrival of Europeans, but it is not certain that they are indigenous. Species of the bean and pepper family are also indigenous, and the former has been cultivated by the natives. Among the many economic plants which have been introduced into Chile and have become important additions to her resources, the more prominent are wheat, barley, rye, oats, and potatoes. The most valuable of all is the grape, a large variety of which have been grown in different parts of the country, and which are now among the most important products of the country. In the cultivation of the grape, the most important of the wine-making districts is the lower valley of the Aconcagua, which is the most southern wine district in the world. The wine is quite an important article of commerce, and is highly esteemed.

Notes of a Naturalist in South America, p. 134.
2 Also classified as Nothofagus (Mirb.).

CHILE
[FLORA AND Fauna]
and Santiago. Oysters of excellent flavour are found in the sheltered waters of Chiloé. The Cetacea, which comprise these southern waters, are represented by four species—two dolphins and the sperm and right whale—and the Phocidae by six species, one of which (Phoca lapissa) differs but little from the common seal. Another species (Macrorhinus leonina), popularly known as the sea-elephant, is provided with short tusks and a short trunk and sometimes grows to a length of 20 ft. Still another species, the sea-lion (Otaria jubata), furnishes the natives of Tierra del Fuego with an acceptable article of food. The fish are largely controlled by adverse climatic conditions, a considerable part of the northern desert being absolutely barren of animal and vegetable life, while the climate of Tierra del Fuego and the southern coast is highly unfavourable to terrestrial animal life, for which reason comparatively few species are to be found. Writing of a journey inland from Quellon, Charles Darwin says (Journal of Researches, &c., p. 444): “Excepting the Vultur aura, ... I saw neither bird, quadruped, reptile, nor insect.” Of his entomological collection in Tierra del Fuego, which was very largely won, he says: “I did not find a single species common to that island and Patagonia. These conditions exist with but few modifications, if any, from the Straits northward to the 42nd parallel, the extreme humidity, abnormally high in the sky, almost making it impossible in the strongest and the tropical north has very few lizards. There are no poisonous snakes in the country, and, in a region so filled with lakes and rivers as the rainy south, only two species of batrachians. The insect life of these strangely associated regions is greatly restricted by adverse climatic conditions, a considerable part of the northern desert being absolutely barren of animal and vegetable life, while the climate of Tierra del Fuego and the southern coast is highly unfavourable to terrestrial animal life, for which reason comparatively few species are to be found. Writing of a journey inland from Quellon, Charles Darwin says (Journal of Researches, &c., p. 444): “Excepting the Vultur aura, ... I saw neither bird, quadruped, reptile, nor insect.”

Population.—The population of Chile is largely concentrated in the twelve agricultural provinces between and including Coquimbo and Concepción, though the next six provinces to the south, of more recent general settlement, have received some foreign immigrants, and are rapidly growing. In the desert provinces the population is limited to the mining communities, and to the ports and supply stations maintained for their support and for the transport, smelting and export of their produce. The province of Atacama has, in addition to its mining population, a considerable number of agriculturists located in a few irrigated river valleys, which class is largely increased in the adjoining province of Coquimbo. The most northern provinces, however, maintain their populations without the support of such small cultivated areas. In the southern territories unfavourable conditions of a widely different character prevail, and the population is restricted to a few small settlements and some nomadic tribes of Indians. Here, however, there are localities where settlements could be maintained by ordinary means and the population could be greatly increased. Since the census of 1805 the population of Punta Arenas has been largely increased by the discovery of gold in the vicinity. The twelve provinces first mentioned, which include the celebrated “Vale of Chile,” comprise only 17% of the area of the republic, but the census of 1805 showed that 72% of the total population was concentrated within their borders. The four desert provinces north of Coquimbo had only 8% of the total, and the seven provinces and one territory south of Concepción had 20%. According to the census of 1805 the total population was 2,712,145, to which the census officials added 10% to cover omissions. This shows an increase slightly over 7% for the preceding decimal period, the population having been returned as 2,527,320 in 1805. The census returns of 1875 and 1886 gave respectively 2,668,447 and 2,714,043. During these years Chile held the anomalous position of a country spending large sums annually to secure immigrants while at the same time her own labouring classes were emigrating by thousands to the neighbouring republics to improve their condition. Writing in 1879, a correspondent of The Times 1 stated that this emigration then averaged 8,000 a year, and in bad times it had reached as many as 30,000. The condition of the Chilean labourer has been much improved since then, however, and Chile no longer suffers so serious a loss of population. In 1895, the foreigners included in the Chilean population numbered 72,812, of which 43,105 were European, 20,668 American, and 1,130 Asiatic, &c. According to nationality there were 8,259 Spanish, 7,809 French, 7,268 Italian, 7,049 German, 6,241 British, 1,570 Swiss, 1,450 Austro-Hungarian, 1,665 Peruvian, 7,681 Argentine, 664 Bolivian, 701 American (U.S.), 797 Chinese. According to residence, 1,471,792 were inhabitants of rural districts, and 1,240,353 of towns. The registration of births, marriages and deaths is compulsory since the 1st of January 1885, but the provisions of the law are frequently eluded. Notwithstanding the healthiness of the climate, the death-rate is high, especially in the large cities. In Santiago and Valparaiso the death-rate sometimes rises to 42 and 60 per 1,000, and infant mortality is very high, being 73% of the births in some of the provincial towns. This unfavourable state of affairs is due to the poverty, ignorance and insanitary habits of the lower classes. The government has made repeated efforts to secure immigrants from Europe, but the lands set apart for immigrant settlers are in the forested provinces south of the Bio-Bio, where the labour and hardships involved in establishing a home are great, and the protection of the law against bandits and criminal assaults is weak. The Germans have indeed settled in many parts of these southern provinces since 1845, and by keeping together have succeeded in building up several important towns and a large number of prosperous agricultural communities. One German authority (Hüber) estimates the number of Germans in two of these provinces at 5,000. The arrivals, however, have been on the whole discouragingly small, the total for the years 1901–1905 being only 14,000.

Although Chileans claim a comparatively small admixture with the native races, it is estimated that the whites and creoles of white extraction do not exceed 30 to 40% of the population, while the mestizos form fully 60%. This estimate is unquestionably conservative, for there has been no large influx of European blood to counterbalance the race mixtures of earlier times. The estimated number of Indians living within the boundaries of Chile is about 50,000, which presumably includes the nomadic tribes of the Fuegan archipelago, whose number probably does not reach 5,000. The semi-independent Araucanians, whose territory is slowly being occupied by the whites, are concentrated in the eastern forests of Bio-Bio, Mallec and Cautín, all that remains to them of the Araucania which they so bravely and successfully defended for more than three centuries. The number of the inhabitants of the Chilian islands, which is being steadily reduced by drunkenness and epidemic diseases, a small part of these Indians live in settled communities and include some very successful stock-raisers, but the greater part live apart from civilization. There are also some remnant tribes in the province of Chiloé, which inhabit the island of that name, the Chonos and Guaytecas archipelagoes and the adjacent mainland, who have the reputation of being good boatmen and fishermen; and there are remnants of a people called Chongos, on the desert coast, and traces of Calchaqui blood in the neighbouring Andean foothills.

There is a wide difference in every respect between the upper or ruling class and the common people. The former includes the landed proprietors, professional men and a part of those engaged in commercial and industrial pursuits. These educated classes form only a small minority of the population. Many of them, especially the landed proprietors, are descendants of the original Spanish settlers and are celebrated for their politeness and hospitality. The political control of the republic was secured to them by the constitution of 1833. The common people were kept in ignorance and practically in a state of hopeless servitude. They were allowed to occupy small homesteads on the large estates on condition of performing certain amount of work for the landlord. Every avenue toward the betterment of their condition was practically closed. The condition of the itinerant labourers (peons) was still worse, the wages paid them being hardly sufficient to keep them from starvation. The Chilean peon, however, comes from a hardy stock, and has borne all
these hardships with a fortitude and patience which go far to counterbalance its faults. Recent reforms in education, &c., together with the growth of manufacturing industries, are slowly leading to improvements in the material condition of the common people.

The political organization of the country has not been favourable to the development of artistic or scientific tastes, though Chile has produced political leaders, statesmen and polemical writers in abundance. Historical literature has been enriched by the works of Diego Barros Arana, Benjamin Vicuña Mackenna, Miguel Luis Amunátegui, Carlos Walker Martínez, and others. One of the earliest native histories of Chile was that of Abbé J. Ignacio Molina, an English translation of which has long been a recognized authority; it is full of errors, however, and should be studied only in connexion with modern standard works. Among them must be included Claude Gay's monumental work, Historia General de Chile, and Sir C. R. Markham's admirable studies on special parts of the subject. In science, nearly all the important work has been done by foreigners, among whom are Charles Darwin, Claude Gay, Eduard Poppig, Rudolph A. Philipps and Hans Steffen, who deserves special mention for his excellent geographical work in the southern Andes.

Divisions and Towns.—Chile contains 23 provinces and one territory, which are subdivided into 75 departments, 855 subdelegations and 3068 districts. The territory north of the Bio-Bio was originally divided into 13 provinces, besides which the Spaniards field Chile, Juan Fernández and Valdivia, the latter being merely a military outpost. During the years which have elapsed since the War of Independence the territory south of the Bio-Bio has been effectively occupied and divided into six provinces, Chiloé and the neighbouring islands and mainland to the coast became a province, and four provinces in the northern deserts were acquired from Bolivia and Peru. In addition to this, Chile claimed Patagonia and the adjacent islands, and has finally secured not only the forested strip of territory west of the Andes, but also a large piece of the Patagonia mainland, south of which is the large archipelago of Tierra del Fuego, and all the western islands. This extensive region, comprising an area of 71,127 sq. m., has been provisionally organized as the territory of Magallanes. For a list of provinces, their areas, reduced from official returns, the populations, and the names and population of their capitals, see the beginning of this chapter.

In addition to the provincial capitals there are few towns of importance. Among these may be mentioned:

The population is not concentrated in large cities, but is well distributed through the cultivated parts of the country. The large number of small towns, important as ports, market towns, or manufacturing centres, is a natural result. Many of the foregoing are only villages in size, but their importance is not to be measured in this way. Arica is one of the oldest ports on the coast, and has long been a favoured port for Bolivian trade because the passes through the Andes at this point are not so high as on the northern line. Moreover, the railway from Arica to La Paz will still further add to its importance, though it may not greatly increase its population. Another illustration is that of Vichuquen, province of Curicó, situated on a tide-water lake on the coast, which is the centre of a large saltpetre making industry. Still another instance is that of Castro, the oldest settlement and former capital of Chiloé, which after a century of decay is increasing again through the efforts to develop the industries of that island.

Communications.—Railway construction in Chile dates from 1850, when work was begun on a short line between Copiapó and the port of Caldera, in the Atacama province, which was opened to traffic in 1853. The first railway to be constructed in central Chile was the government line from Valparaíso to Santiago, which was opened to traffic in 1853. About the same time the government began the construction of a transcontinental line running southward from Santiago, passing through Chiloé, and the Coast range, and connecting with all the provincial capitals and prominent ports. This is the only railway line which is not wholly constructed from the coast at several points to inland mining centres. One of these, running from Antofagasta to the Caracoles district, was afterwards extended to Oruro, Bolivia, and has become a commercial route of international importance, with a total length of 1,428 m. In addition to this, the line to Calama, which was opened to traffic in 1863, has been extended to the west coast of the desert region originated at a time when the territory belonged to Chile. It should be remembered that many of these railway enterprises of the desert region originated at a time when the territory belonged to Chile. CHILE

Uspallata pass. A further Transandine scheme provides for a line through the Pino Hachado pass (38° 30' to 39° S.), and the Argentine Great Southern Company obtained a concession in 1909 to extend its Neuquen line to the frontier of Chile. The railways of the republic had at an average length of 2,606 m. by 1905, a total of 6,825 m., of which 4,895 m. were owned by the state, and 1,930 m. belonged to private companies. The private lines are located in the northern provinces and are for the most part built and maintained for the transportation of mining products and supplies into the interior. In recent years her railway lines have about 21,000 m. of public roads of all descriptions, 1,35 m. of tramways, and 706 m. of navigable river channels, besides a very considerable mileage of lake and coast navigation.

Telegraphic communication between all the important points of the coast and a large number of the interior towns is maintained by the state, in which there were in 1909 930 m. of line in a total of 11,080 m. Cable communication with Europe by way of Buenos Aires was opened in 1875, and is now maintained by the state, and other private cables extend along the coast 32 m. in length. A West Coast cable also connects with Europe and North American states by way of Panama. There were 15,853 m. of telephone wires in the republic in 1906, all the principal cities having an admirable service. There are said to be 14,900 miles of good and average in length, free, as means of popular instruction. The postal rates for 1904 amounted to 2,775,730 pesos and the expenditures to 2,407,753 pesos.

Chile is a member of the International Postal Union, and has arranged treaty with the principal commercial nations for the exchange of postal money values.

Agriculture.—According to the census returns about one-half of the population of Chile lives in rural districts, and is engaged nominally at least in some form of agriculture. The land is not uniformly productive, and the internal trade is well developed, but it is singularly well adapted to agriculture. The northern part of this region has a sub-tropical climate, light rainfall and a long, dry summer, but with irrigation it produces a great variety of products. Alfalfa, or lucerne (Medicago sativa), is grown extensively for shipment to the mining towns, and its produce is sold at a high rate in the southern port of Concepcion. Although wheat is grown in the northern part of this region, it is grown with greater success in the south, where the rainfall is lower. Cereal crops are grown directly in the fields and not in fields or paddies. The principal field crops are barley, wheat, oats, rye, and potatoes. The great river valleys offer the most favorable conditions for cereal production. The Argentine and Chilean provinces are almost destitute of natural forests, and their chief sources of wood are the native or wild forests, which are heavy and suited for fuel. Logs from the western side of the range are shipped down the streams to the coast, and by means of a series of sawmills on the same coast are converted into a variety of manufactured wood products, such as pulp, newsprint, etc.

The southern provinces are well adapted to fruit culture. The principal fruits are grapes and pears, although the latter are not produced in large quantities. The chief wine-producing districts are the valleys of Coquimbo and Aconcagua, and tobacco is produced on a small scale in the northern part of the country. The chief crops are also the latter, and wheat, barley, potatoes, and barley are the principal exports. The wheat is grown on the high plateaus of the south, and the barley is produced in the southern part of the country.

The chief industries of Chile are mining, the scope of which is very extensive, and is based on the diversified natural wealth of the country. The principal minerals are copper, gold, silver, iron, and coal, and the chief productions are copper, gold, silver, and iron. The principal export is copper, and the chief producing districts are Coquimbo and Aconcagua.

The principal industries of Chile are mining, the scope of which is very extensive, and is based on the diversified natural wealth of the country. The principal minerals are copper, gold, silver, iron, and coal, and the chief productions are copper, gold, silver, and iron. The principal export is copper, and the chief producing districts are Coquimbo and Aconcagua.
Manufactures.—The manufacturing interests of Chile have become so influential that the leather industry is especially important, and large establishments for the manufacture of leather products have been established in the south of the country. Brewing and distilling have made notable progress, and the domestic consumption of beer is very large. The beer is generally produced and consumed in the southern provinces, where the climate is more suitable for brewing.

The manufacture of machinery is becoming increasingly important, and there are several factories engaged in the production of machinery and other industrial goods.

The mining industry has been developed to a great extent, and many valuable mineral deposits have been discovered. The most important minerals are copper, silver, gold, and iron. The production of copper has increased steadily, and Chile is now one of the leading copper-producing countries in the world. The copper mines are located in the Atacama desert region, and the chief copper-producing districts are the Tarapaca, Antofagasta, and Atacama provinces.

The production of silver is also important, and the silver mines are located in the Andes and the Atacama desert region. The production of gold is also significant, and the gold mines are located in the Andes and the Atacama desert region.

The production of iron is also important, and the iron mines are located in the northern part of the country.

The production of coal is also significant, and the coal mines are located in the north of the country.

The production of sulfur is also important, and the sulfur mines are located in the Atacama desert region.

The production of saltpetre is also significant, and the saltpetre mines are located in the Antofagasta province.

The production of borax is also important, and the borax mines are located in the Atacama desert region.

The production of guano is also significant, and the guano deposits are located in the Atacama desert region.

The production of salt is also important, and the salt deposits are located in the Atacama desert region.

The production of wood is also significant, and the wood deposits are located in the Atacama desert region.

The production of leather is also important, and the leather deposits are located in the Atacama desert region.

The production of tobacco is also significant, and the tobacco deposits are located in the Atacama desert region.

The production of tea is also significant, and the tea deposits are located in the Atacama desert region.

The production of sugar is also significant, and the sugar deposits are located in the Atacama desert region.

The production of rice is also significant, and the rice deposits are located in the Atacama desert region.

The production of hops is also significant, and the hops deposits are located in the Atacama desert region.

The production of cotton is also significant, and the cotton deposits are located in the Atacama desert region.

The production of wool is also significant, and the wool deposits are located in the Atacama desert region.

The production of oil is also significant, and the oil deposits are located in the Atacama desert region.

The production of gas is also significant, and the gas deposits are located in the Atacama desert region.

The production of coal is also significant, and the coal deposits are located in the Atacama desert region.

The production of iron is also significant, and the iron deposits are located in the Atacama desert region.
ADMINISTRATION

CHILE

151
days, and with the consent of the council of state may convene it in an extraordinary session. Congress has the privilege of giving or withholding its confidence in the executive of the government, or of compelling the resignation of any one of the ministers of state, or of compelling the president of the republic to order the removal of any of them, and that resolution, if it be adopted, is inoperative, and is incapable of being forced, unless the president signs it. The session of the congress is for three years, and the president is chosen by the congress. The president is elected for a term of five years, and is ineligible for the next succeeding term. He is chosen by electors, who are elected by the people in the manner prescribed for deputies, and in the proportion of three electors for each deputy. These elections are held on the 25th of June in the last year of a presidential term, and the electors cast their votes on the 25th of July, and the counting takes place in a joint session of the two chambers of congress on the 30th of August, congress in joint session having the power to complete the election when no candidate has been duly chosen by the electors. The formal installation of the president takes place on the 18th of September, the anniversary of the declaration of national independence. In addition to the prerogatives commonly invested in his office, the president is authorized to supervise the judiciary, to nomicate and appoint the candidates for the higher ecclesiastical offices, to intervene in the enforcement of ecclesiastical decrees, papal bulls, &c., to exercise supervisory police powers, and to appoint the intendants of provinces and the governors of departments, who in turn appoint the sub-delegates and inspectors of subordinate political divisions, who in turn appoint the presidents of the municipalities, and who, in order to be native-born, not less than thirty years of age, and eligible for election to the lower house. He is assisted and advised by a cabinet of six ministers whose departments are: interior, foreign affairs, worship and colonization, justice and public instruction, war and marine, finance, industry and public works. In case of a vacancy in the presidential office, the minister of interior becomes the “vice-president of the republic” and discharges the duties of the executive office until a successor can be legally elected. A council of state of 12 members, consisting of the president, 6 members appointed by congress and 5 by the president, has advisory functions, and its approval is required in many executive acts and appointments.

The provinces are administered by intendentes, and the departments by gobernadores, both appointees of the national executive. The sub-delegacies are governed by sub-delegados appointed by the governors, and the districts by inspectores appointed by the sub-delegates. Directly and indirectly, therefore, the administration of all these political divisions is in the hands of the intendentes. The intendentes, who, in like manner, makes and controls the appointments of all judicial functionaries, subject, however, to receiving recommendations of candidates from the courts and to submitting appointments to the approval of the council of state. This gives the national executive absolute control of all administrative matters in every part of the republic. The police force also is a national organization under the immediate control of the minister of interior, and the public prosecutor in every department is a representative of the national government. There is no legislative body in any of these political divisions, nor any administrative official directly representing the people, with this exception: under the law of the 22nd of December 1891, municipalities, or communes, are created and invested with certain specified powers of local government affecting local police services, sanitation, local improvements, primary instruction, industrial and business regulations, &c.; they are authorized to borrow money for sanitary improvements, road-making, education, &c., and are entitled to receive support from general taxation; these municipalities elect their own alcaldes, or mayors, and municipal councils, the latter having legislative powers within the limits of the law mentioned.

Justice.—The judicial power consists of a Supreme Court of Justice of seven members located in the national capital, which exercises supervisory and disciplinary authority over all the law courts of the republic. The appeal, in Taena, Serena, Valparaiso, Santiago, Talca and Concepcion, are appeal courts, and receive cases from the provinces, and are authorized to hear and determine appeals from the judgments and final sentences of the lower courts, and make decrees on points of jurisdiction, and to determine the causes of suits between states and foreign states, and to decide disputes arising between the state and its national municipalities, or communes, or with respect to their boundaries, and to hear and determine cases of title to real property in the sense of the law. The Supreme Court of Justice is the highest court of law in the republic. There are in each of the provinces a Court of Appeals; in each of the capitals, and municipal courts, or justices of the peace, in the sub-delegacies and districts. The jury system does not exist in Chile, and juries are unknown except in cases where the freedom of the press has been abused. All trials, therefore, are heard by one or more judges, and appeals may be taken from a lower to a higher court. The government is represented in each department by a public prosecutor. The police officials, who are under the direct control of the minister of interior, also exercise some degree of judicial authority. This force is essentially military in its organization, and consisted in 1901 of 500 officers, 934 non-commissioned officers and 2400 police soldiers. Small forces of local policemen are supported and trained by the regular army. The police force is organized by the national executive, and those of the minor tribunals by the federal official governing the political division in which they are located.

For military purposes the republic is divided into five districts, the northern desert provinces forming the first, the central provinces as far south as the Bio-Bio the second and third, and the southern provinces and territory the fourth and fifth. Large sums are annually expended in the support of the regular army, which is concentrated in a general staff comprising six service departments, at the head of which is a chief of staff. After the triumph of the revolutionists in the civil war of 1891, the army was reorganized under the direction of Colonel Martinez, an accomplished organizer, who subsecdingly served as chief of the general staff. In 1904 the permanent force consisted of 12 battalions of infantry, 6 regiments of cavalry, 4 regiments of mountain artillery, 1 regiment of horse artillery, 2 regiments of coast artillery, and 5 companies of field artillery. In the same year 1000 officers were trained, and 8000 men were added 6100 recruits, the contingent for that year of young men twenty-one years of age compelled to serve with the colours. Under the law of the 5th of September 1900, military service is obligatory for all males, and the service of 2000 men are annually being required to serve a certain period with the regular force. After this period they are transferred to the 1st reserve for 9 years, and to the 2nd reserve. The military rifle, in the United States model, of 7 mm. calibre, and the batteries are provided with Krupp guns of 7 and 7.5 cm. calibre. Military instruction is given in a well-organized military school at Santiago, a war academy and a school of military engineering.

Navy.—The Chilean navy is essentially British in organization and methods, and all its best fighting ships were built in British yards. In 1906 the effective fighting force consisted of 1 battleship, 1 armored cruiser, 6 destroyers, and 6 modern torpedo boats. In addition to these there are several inferior armed vessels of various kinds which bring the total up to 40, not including transports and other auxiliaries. The navy is divided into two branches: the Frogs, consisting of the ships of war, and the marine, is confided to a general naval staff, called the “Director General de la Armada,” with headquarters at Valparaiso. Its duties also include the military protection of the ports, the hydrographic survey of the coast, and the lighthouse service. The personnel comprises about 465 officers, including those of the staff, and 400 petty officers and men. There is a military port at Talcahuano, in Concepcion Bay, strongly fortified, and provided with arsenal and repair facilities. The Fleet is protected, contrary to the practice of other naval stations, by 40000 m. of concrete road, and the entire water-way occupies one of the noteworthy edifices of Valparaiso, is attended by 90 cadets and is noted for the thoroughness of its instruction.

Education.—Under the old conservative régime very little was done for the public schools, and the portion of the labouring classes who could not find their way into the public service and the religious orders, which occupied the leading positions of the schools, received comparatively little attention. The increasing influence of more liberal ideas greatly improved the state of education, and the government undertook to prosecute each of the public schools with reference to regular education, and the government now makes vigorous efforts to bring its public school system within the reach of all. The constitution provides that free instruction must be provided for the people. School attendance is not compulsory, however, and the gain upon illiteracy (75%) appears to be steady. One of the great gains is the organized work among the gangs when serving with the colours, which, with the increasing employment of the people in the towns, helps to stimulate a desire for education among the lower classes. Education in Chile is very highly organized, and the National Institute, with the direction of justice and public instruction being charged with the direction of all public schools from the university down to the smallest and most remote primary school. The system includes the University of Chile, the National Institute of Education, the Normal Schools in all the provincial capitals and larger towns, normal schools at central points for the training of normal public school teachers, professional and industrial schools, military schools and primary schools. Instruction is free to girls. The law of 1892, which regulates the admission of girls, is free, but only to a limited extent, known as free, when they are supplied. In the normal schools, where the pupils are trained to enter the public service as primary teachers, not only is the tuition free, but also books, board, lodging and everything needed in their training is supplied. The Institute of Education includes departments of theology, law and political science, medicine and pharmacy, natural sciences and mathematics, and philosophy. The range of studies is wide, and the attendance large. The National Institute is the principal high school of the secondary grade in Chile. There were 30 of these high schools for males and 12 for females in 1903, with an aggregate of 11,504 matriculated students. The normal schools for males are located at Santiago, Chillan and
CHILE

Valdivia; and for females at La Serena, Santiago and Concepción. The mining schools at Copiapó, La Serena and Santiago had an aggregate attendance of 180 students in 1903, and the commercial schools at Iquique and Santiago an attendance of 214. The most important agricultural schools are located at Santiago, Talca, La Serena, Antofagasta, and Arica; and a night school of industrial drawing in the same city, and professional schools for girls in Santiago and Valparaíso, where the pupils are taught tailoring, dress-making, knitting, embroidery and needlework. There are also, in some of these institutions, classes for the blind and for the deaf and dumb. The public primary schools numbered 1961 in 1903, with 3668 teachers, 166,928 pupils enrolled, and an average attendance of 108,582. The cost of maintaining these schools was 4,145,575 pesos, or an average pupil in attendance. In addition to the public schools there are a Roman Catholic university at Santiago, which includes law and civil engineering among its regular courses of study; numerous private schools and seminaries of the secondary grade, with a total of 11,156 students of both sexes in 1903; and 106 private primary schools, with an attendance of 29,684. The private schools usually conform to the official requirements in regard to studies and examinations, which facilitates subsequent admission to the national university and the obtaining of available scholarships probably better than the public schools, especially in the German settlements of the southern provinces. A Consejo de Instrucción Pública (council of public instruction) of 14 members exercises a general supervision over the higher schools. Of the public schools a considerable number belong to the Catholic Church.

Charity.—According to the returns of 1903 there were 88 hospitals in the republic, which reported 79,957 admissions during the year. In these institutions under the care of the Sisters of Charity of the Divine Providence 78,331 patients received gratuitous medical assistance at the public dispensary during the year: there were 24 foundling hospitals with 5570 children; and there were 3062 persons in the various hospicios or orphanages, and 13,489 in the insane asylums.

Religion. The Roman Catholic religion is declared by the constitution to be the religion of the state, and the inaugural oath of the president pledges him to protect it. A considerable part of its income is derived from a subsidy included in the public budget which does not exceed 100,000 pesos yearly. The Catholic Church, however, is not compulsory like any other public service. The secular supervision of this service is entrusted to a member of the president's cabinet, known as the minister of worship and colonization. The executive and legislative powers in religious matters are invested in the Consejo Permanente de Religiones, which is elected by the president.

The greater part of the population remains loyal to the established faith. The law of 1865 gives the privilege of religious worship to other faiths, and the laws of 1883 made civil marriage and the civil registry obligatory. It is evident, however, that the Roman Catholic church is dominant in the country. The law of 1865 is practically acted, and it is provided that the services of religious organizations other than the Roman Catholic be held in private residences and not to exceed an average of only 8,200 pesos per month. The community is not subject to taxation. Of the 72,812 foreigners residing in Chile in 1895, about 16,000 were described as Protestants. Notwithstanding the opposition of some political elements to the Church, the Chileans themselves may all be classed as Catholics. The ecclesiastical organization includes a patriarch, who resides at Santiago, three bishops residing at La Serena, Concepción and Ancud, and two vicars residing in Antofagasta and Tarapacá.

Finance.—For a long time Chile was considered one of the poorest states of Spain America, but the acquisition of the rich mineral-producing provinces of the north, together with the development of the agricultural industry, has increased her revenues and enabled her to develop other resources. During the decades 1831-1840 the annual revenues averaged about 2,100,000 pesos (of 40d.), which in the decade 1861-1870 increased to an average of 6,200,000 pesos, and during a period of considerable agricultural activity on account of wheat exports to California and Australia. After 1870 the revenues increased more rapidly owing to the development of new mining industries, the receipts in 1879 amounting to 15,300,000 pesos, and in 1882 to 25,000,000 pesos. The revenues from the captured Peruvian nitrate fields then became an important part of the national income, which ten years later (1902) reached an aggregate of 135,507,175 pesos (of 18d.), of which 105,072,832 pesos were in gold. In 1906 the receipts from all sources were estimated at 149,100,000 pesos of which 62,200,000 pesos gold were credited to the national treasury, 39,800,000 pesos gold to import duties, and 23,500,000 pesos currency to railway receipts. During these years of fiscal prosperity, the country suffered much from financial crises caused by industrial stagnation, and expenditure increased, owing to the pressure of public demands and pressure. To ensure an income that would meet its foreign engagements, the government collected the nitrate and iodine taxes and import duties in gold. As a considerable part of the expenditures were in gold, the practice was adopted of keeping the gold and currency of the state separate. When the Customs Act was passed in 1864, the exchange rate of the peso was reduced to 18d., at which rate the outstanding paper should be redeemed. A conversion fund was also created, and, although the government afterwards authorized two more large issues of paper currency, it is believed that the customs regulations were modified in 1907 to permit the payment of import duties in paper. The national revenue is derived chiefly from the nitrate taxes, customs duties, alcohol tax, and from railway, telegraph and telephone receipts. There is no land tax, and business or business taxes are levied by the municipalities for local purposes. The national expenditures are chiefly for the interest and amortization charges on the public debt, official salaries, military expenses in connection with the army and navy, public works (including railway construction, port improvements, water and sewage works), the administration of the state railways, telegraph lines and post office, church subsidies, public instruction and foreign representation.

The ordinary and extraordinary receipts and expenditures for the five years 1899-1903, in gold and currency, in pesos of 18d., were as follows:

For 1905 the expenditures were fixed at 149,000,000 pesos, and the receipts were estimated to produce 149,100,000 pesos, which included 62,200,000 pesos gold from nitrate taxes, 39,800,000 pesos gold and 200,000 pesos paper from import duties, 23,500,000 pesos paper from the state railways, 2,500,000 pesos of inland tax, and 7,000,000 pesos gold from loans. How the revenues are expended is shown in the estimates for 1907, in which the total expenditures were estimated at 134,830,532 pesos gold and 8,796,760 pesos gold, the principal appropriations being for the payment of the nitrate debt, 2,550,000 pesos, and the military and naval establishments, 5,425,000 pesos. The receipts from the nitrate and iodine taxes amounted to 62,200,000 pesos, and the circulation of 90,900,000 pesos; the receipts from the state railways were 2,500,000 pesos, and the postal and telegraph receipts amounted to 500,000 pesos. The receipts from the national debt were on the average 1,775,217,704 pesos, of which 1,020,609,215 pesos were in urban loans and 66,600,000 pesos in rural loans. The national debt in 1906 amounted to 1,757,217,704 pesos, of which 972,357,153 pesos gold were paid to foreign creditors, and 28,460,571 pesos were in gold; these figures, however, do not include the national debt of about 12,500,000 pesos, the national debt in 1907 amounted to 1,775,217,704 pesos, of which 1,020,609,215 pesos were in urban loans and 66,600,000 pesos in rural loans. The national debt in 1906 amounted to 1,757,217,704 pesos, of which 972,357,153 pesos gold were paid to foreign creditors, and 28,460,571 pesos were in gold; these figures, however, do not include the national debt of about 12,500,000 pesos, and in 1906 the new 4% bond was issued at 102 3/4, and the 4% bond to the amount of 8,000,000 pesos on the Arica-La Paz railway. The custom of dividing receipts and expenditures into ordinary and extraordinary, of treating the receipts from loans as revenue, of adding six months to the fiscal year for closing up accounts, and of adding receipts and expenditures into separate gold and currency accounts, leads to much confusion and complication in the returns, and is the cause of unavoidable discrepancies and contradictions.

1 The expenditures of 1902 are also given as 28,882,702 pesos gold, and 108,844,693 pesos currency.
The first Spanish invasion of Chile took place in 1535, when Diego de Almagro, the companion and rival of Pizarro in the conquest of Peru, marched into Chile in search of gold. Disappointed in his quest, and meeting with obstinate resistance from the southern tribes, he returned to Peru with his whole force in 1538. In 1540 Pizarro sent Pedro de Valdivia to make a regular conquest and settlement of Chile. Valdivia founded Santiago, the present capital of Chile, in February 1541, and proceeded to build the towns of La Serena, Concepción, Villarica, Imperial, Valdivia and Angol, in order to secure his hold on the country. But the Indians fought desperately for their independence, and in 1553 a general rising of the tribes ended in the defeat and death of Valdivia and in the destruction of most of his settlements. This was the beginning of nearly a century of continuous warfare. As there was no gold in the country the number of settlers was small, the loose tribal organization of the natives made it impossible to inflict a vital defeat on them, and the mountainous and thickly wooded country lent itself admirably to a warfare of surprises and ambushes. General after general and army after army were despatched from Spain and Peru; Chile was given a government independent of the viceroy of Lima; attack after attack was made on the Indians, their lands were laid waste, and the struggle was conducted with merciless ferocity: all in vain. Settlements and forts were never free from assault and were taken and retaken; if one Indian army was destroyed another took its place, if one toqui was killed another was chosen; when defeated, the Indians retired to their forests, marshes and hills, recruited their forces, and fell on the pursuing Spaniards.

In 1612 an attempt was made by a Jesuit missionary to negotiate a peace, but not till 1640 was the desperate struggle ended by the treaty of Quillin, which left the Indians all the land south of the Bio-bio river. Up to 1800 the peace was broken by three wars; in 1655, in 1723 and in 1766, the last ended by a treaty which finally gave the Araucanians the right to have a minister at Santiago.

It was this constant warfare with the Indians and the necessity for hard continuous work, owing to the lack of precious metals in Chile, that no doubt helped to produce in the settlers the strength and hardihood of character that distinguishes the Chileans among South American races. But not unnaturally the material condition of the country was the reverse of prosperous. The expenditure far exceeded the revenue. The Indian warfare occupied nearly the whole attention of the governors and much of the time of the settlers. By the Spanish colonial system the development of manufactures was prohibited and the trade of the colony was limited not only to Spain but to the one port of Cadiz. Till the 18th century ships were not allowed to sail round Cape Horn, so that the Chileans had to trade indirectly through Peru and the Argentine. Agriculture was the one resource of the colony, and wheat was grown for export to Peru, but the land was concentrated in the hands of a few hacendados, and the cultivation of the vine and olive was forbidden.

The end of the 17th century Santiago was a town of poor one-storied houses and had only 8000 inhabitants; the other towns, Valparaiso, Concepción, La Serena, were only large villages. Books were not allowed to be imported, and education was limited to such as was given here and there by priests and monks. The Indians within the limits of the Spanish colony were treated like slaves, and horribly mutilated to prevent their escape; but at the same time a gradual fusion of races was taking place, and the Chilean peasant (peon) of to-day is as much of Indian as of Spanish descent. The Araucanians, however, continued to preserve their independence; they jealously resented the introduction of Spanish influence, and the missionary efforts of the Jesuits met with little success.

During the 18th century the condition of the colony was improved in many ways. The Bourbon kings of Spain were more liberal in their colonial policy. Merchant-ships were allowed to sail direct to Chile, trade with France was sometimes permitted, and a large batch of hardy emigrants was sent out.
from the Biscay provinces of Spain. Freed from the preoccupation of the Indian wars, the governors gave more attention to the general welfare of the country: a university was started in Santiago in 1747, many towns were built about the same time, agriculture and industries were promoted and a coasting trade grew up. In 1778 Charles III. threw open all the ports of Spain to the colonies and allowed freedom of trade with France. But in general the administration of the colony was burdensome, oppressive and inefficient. The people had no voice in the government. Ruling with the help of the Royal Audience, the governor was absolute master of the country, and regulated the smallest details of life. Such time as the officials could spare from the main object of enriching themselves by extortion and corruption was given up to endless official and religious ceremonies and to petty disputes of etiquette and precedence. All the high posts and offices were filled by men sent from Spain, with the result that bitter jealousy reigned between them and the native-born colonists (criollos). The criollos as a rule filled the posts in the municipalities (cabildos), disposed of by sale, so that when the revolution broke out the cabildos naturally became the centres of the movement. As in all Spanish colonies, so in Chile, the Church played a large part in the public life. Chile was a great country of large estates, and the Church managed to accumulate most of the wealth of the country. At the same time the monks and Jesuits did useful work in teaching industrial and agricultural arts, and in giving the people a certain degree of education; but the influence of the Church was used to bolster up the traditional narrow colonial system, and the constant quarrels between the clergy and the secular powers often threw the country into confusion.

At the opening of the 19th century Chile was a colony whose resources had hardly been touched, with a population of about 500,000 persons, of Spanish and mixed Spanish and Indian blood: a people endowed with the vigour of character bred by a mountainous country and a bracing climate and by a hard struggle for existence, but ignorant through lack of education, shut out by a narrow-minded commercial system from knowledge of the outside world, and destitute of the character-training that free institutions afford.

The independence of Chile dates from the second decade of the 19th century. The revolt of England's North American colonies and the American Revolution naturally suggested the idea of a struggle for independence to the Spanish colonists, and the deposition of Ferdinand VII. by Napoleon, and the ensuing disorganization of Spain, supplied the desired opportunity. In 1809 risings took place in Venezuela, in Ecuador, in Upper Peru and in the Argentine; the revolutionary fever spread to Chile, and on the 18th of September 1810 the cabildo of Santiago secured the resignation of the governor and vested his powers in an elected Junta (board) of seven members. This event was the beginning of the independence of Chile. But it was some time before independence was fully attained. The mass of the people were ignorant, intercourse between them was slight, and there was a strong section attached to the old régime. The party determined on independence was at first small, and compelled to conceal its aims till the ground had been prepared for open decisive action. Further, there were divisions between the patriots of Santiago and those of Concepción, and bitter jealousies between the leaders, the chief of whom were Juan Martínez de Rozas, José Miguel Carrera and Bartolomé O'Higgins. O'Higgins and Rozas, as the bishops and the enemies existing among the leaders, the Spanish forces, sent by the viceroy of Peru to crush the revolutionary movement, succeeded after two years' indecisive fighting in completely defeating the patriots at Rancagua in 1814. For three years the Spaniards maintained their hold on Chile, ruling the country with tyrannical harshness, but in the spring of 1817 a patriot force which had been organized at Mendoza in the Argentine by José de San Martín, an Argentine officer, and by O'Higgins, crossed the Andes and overwhelmed the royalists at the battle of Chacabuco. O'Higgins was named director-general of Chile, while San Martín, realizing that the independence of each colony depended on the Spanish being expelled from the whole of South America, set about preparing an invasion of Peru. The vicerey of Lima made one more effort to uphold the power of Spain in Chile, but the army he despatched under Mariano Osorio, the victor of Rancagua, was decisively defeated at the river Maipo on the 3rd of April 1818. By this battle the independence of Chile, formally proclaimed by O'Higgins in the previous February, was finally secured.

The next few years witnessed the expulsion of the royalists from the south of Chile, the establishment of a small fleet, placed under the command of Manuel Blanco Encalada and Lord Cochrane (earl of Dundonald), and the invasion of Peru by San Martín with the help of the fleet, ending in the proclamation of Peruvian independence in 1821; though the Spanish power was not finally broken until Bolívar's victory at Ayacucho in 1824. Relieved from all fear of Spanish attacks from the north, the new republic of Chile entered upon a period of internal confusion and dissension bordering upon anarchy. As soon as the necessity for establishing a stable government arose the lack of training in self-government among the Chileans became painfully obvious. O'Higgins as director-general, rightly perhaps, considered that firm orderly government was more important than a liberal constitution, and his administration roused strong hostility. Gradually he was compelled to resign. From that date up to 1830 there were no less than ten governments, while three different constitutions were proclaimed. The nation was divided into small mutually hostile parties; there were ecclesiastical troubles owing to the hostility of the Church to the new republic; there were Indian risings in the south and royalist revolts in the island of Chiloé; the expenditure exceeded the revenue, and the employment of the old Spanish financial expedients naturally increased the general discontent. Up to 1830 the Liberal party, which favoured a free democratic régime, held the upper hand, but in that year the Conservatives, backed by a military rising led by General Joaquín Prieto, placed themselves in power after a sanguinary battle at Lircay. Prieto was elected president in 1831, and a new constitution was drafted and promulgated in 1833, which, with some modifications, remains the constitution of Chile at the present time. This constitution invested the executive with almost dictatorial powers, and the Conservatives entered upon a period of reaction and reaction.

The aim of the Conservative policy was to secure above all a strong administration; power was concentrated in the hands of a small circle; public liberties were restricted and all opposition crushed by force. Inaugurated under General Prieto's administration (1831-1841) by his able minister Diego Portales, this policy was continued by his successors General Manuel Bulnes (1841-1851) and Manuel Montt (1851-1861), each of whom like Prieto was elected to a double term of office. In spite of the discontent of the Liberals, the Conservative ascendency secured a long period of firm stable government, which was essential to put an end to the confusion in public life and to give time for the people to awake to a fuller realization of the duties and responsibilities of national independence. The internal peace of the country was only disturbed three times, by Liberal risings in 1835, in 1851 and in 1859, all of which were crushed, but without severe fighting. In 1836 Chile also became involved in a war with a confederation of Peru and Bolivia, which ended in the victory of Chile and the dissolution of the confederation. While refusing to allow the people any share in, or control over, government, the government allowed themselves to improving the condition of the people and of the country, and under their firm rule Chile advanced rapidly in prosperity. The government established a department for education, a training college for teachers, and numerous schools and libraries; literary magazines were started and a school of art and an academy of music founded. By the consolidation of the foreign debt, by the regular payment of interest, by the establishment of several banks, and by the negotiation of commercial treaties, the financial position of the country was improved. Internal development was promoted by the working
of the silver mines of Copiapó and the coal mines of Lota, by the building of railways and erection of telegraphs, and by the colonization of the rich Valdivia province with German settlers.

The Straits of Magellan were occupied; under an American engineer, William Wheelwright, a line of steamers was started on the coast, and, by a wise measure allowing merchandise to be landed free of duty for re-exportation, Valparaíso became a busy port and trading centre; while the demand for food-stuffs in California and Australia, following upon the rush for gold, gave a strong impetus to agriculture. A code of law was drawn up and promulgated, and the ecclesiastical system was organized under an archbishop appointed by the pope. To Montt, as minister under Bulnes and afterwards as president, must be given the main credit for the far-seeing policy which laid the foundations of the prosperity of Chile; and though the administration was in many ways harsh and narrow, firm government, rather than liberty that would have tended to anarchy, was essential for the success of the young republic.

After 1861, however, a Liberal reaction set in, aided by divisions in the Conservative party arising mainly over church questions. Montt's successors, José Joaquín Pérez (1861–1871), Federico Errázuriz (1871–1875), and Pinto (1875–1881), abandoned the repressive policy of their predecessors, invited the co-operation of the Liberals, and allowed discontent to vent itself freely in popular agitation. Some democratic changes were made in the constitution, notably a law forbidding the re-election of a president, and the gradual and peaceful transition to a Liberal policy was a proof of the progress which the nation had made in political training. Outside the movement for constitutional reform, the most important internal question was the successful Liberal attack on the privileged position and narrow views of the Church, which led to the birth of a strong ultramontane party among the clergy. The government continued to be animated by a progressive spirit: schools, railways, telegraphs were rapidly extended; a steamship mail service to Europe was subsidized, and the stability of the government enabled it to raise new foreign loans in order to extinguish the old high interest-bearing loans and to meet the expenses of public works. In 1877 a financial crisis occurred, met by the emission of paper money, but the depression was only temporary, and the country soon rallied, and the prestige of General Errázuriz was such that the ships were obtained and the officers trained that did such good service in the great war with Peru. With a population of over two millions, a rapidly increasing revenue, ruled by a government that was firm and progressive and that enjoyed the confidence of all classes, Chile was well equipped for the struggle with Peru that began in 1879.

The war of 1879–82 between Chile and Peru is the subject of a separate article (see CHILE-PERUVIAN WAR). By the beginning of 1881 the war had reached a stage when the final struggle was close at hand. On the 13th of January of that year the Chilean forces under command of General Baquedano attacked the entrenched positions of the Peruvians at daybreak in the vicinity of Chorillos, a village some few miles from Lima, and forcing the outer line of defence for the capital. After a stubborn fight the day ended in victory for the attacking forces; but the losses on both sides were great, and on the following day negotiations for peace were attempted by the representatives of the foreign powers in Lima, the object being to avoid, if possible, any further bloodshed. This attempt to end the conflict proved, however, abortive, and on the 15th of January at 2 p.m. hostilities recommenced in the neighbourhood of Miraflores. After severe fighting for some four hours the Chileans again proved victorious, and drove the Peruvians from the second line of defence back upon the city of Lima. Lima was now at the mercy of the Chileans, and on the 17th of January a division of 4000 men of all arms, under the command of General Cornelio Saavedra, was sent forward to occupy the Peruvian capital and restore order within the town limits. A portion of the Chilean forces was shortly afterwards withdrawn from Peru, and the army of occupation remaining in the conquered country was in charge of Admiral Patricio Lynch, an officer who had been specially promoted for distinguished services during the war. President Aníbal Pinto of Chile now set about to find means to conclude a treaty of peace with Peru, but his efforts in this direction were frustrated by the armed resistance offered in the country districts to the Chilean authorities by the remainder of the Peruvian forces under command of General Cáceres. So matters continued—the Chileans administering on the seaboard and in the principal towns, the Peruvians maintaining a guerrilla warfare in the mountainous districts of the interior. In September 1881 the term of office of president Pinto expired, and he was succeeded in the post of chief executive of Chile by President Domingo Santa María. Ex-President Pinto died three years later in Valparaíso, leaving a memory respected and admired by all.

Señor Domingo Santa María, who now succeeded to the presidency of Chile, was a Liberal in politics, and had previously held various important posts under the government. Under the rule of President Montt he had been an active member of the opposition and involved in various revolutionary conspiracies; for his participation in these plots he was at one time exiled from the country, but returned and received official employment under President Pérez. The principal task confronting President Santa María on assuming the presidency was to negotiate a treaty of peace with Peru and provide for the evacuation of the Chilean army of occupation. The presence of the Peruvian general Cáceres and of the Peruvian fleet, which was in the interior of Peru, prevented for two years the formation of any Peruvian national administration, in Lima with which the Chilean authorities could deal. In August of 1883 the Peruvians were defeated by the forces commanded by Admiral Lynch, and a government was then organized under the leadership of General Iglesias. A provisional treaty of peace was then drawn up and signed by General Iglesias and the Chilean representative, and this was finally ratified by the Chilean and Peruvian congresses respectively in April 1884. By the terms of this treaty Peru ceded to Chile unconditionally the province of Tarapacá, and the provinces of Tacna and Arica were placed under Chilean authority for the term of ten years, the inhabitants having then to decide by a general vote whether they remained a part of Chile or elected to belong once more to Peru. In the event of the decision being favourable to Peru a sum of 5,000,000 pesos was to be paid by Peru to Chile. On the ratification of this treaty the Chilean forces were immediately withdrawn from Lima and other points of occupation in Peruvian territory. The government of Bolivia also attempted to negotiate a treaty of peace with Chile in 1884, and for this purpose sent representatives to Santiago. No satisfactory terms, however, could be arranged, and the negotiations ended in merely an armistice being agreed to, by which Chile remained in occupation of the Bolivian seaboard pending a definite settlement at some future period.

The administration of President Santa María met with violent opposition from the Conservatives, who included the Clerical party in their ranks, and also from a certain section of the Liberals. The dislike of the Conservatives to President Santa María was occasioned by his introduction of the law of civil marriage, the civil registration of births and deaths, and the freeing of the cemeteries. Hitherto no marriage was legal unless celebrated
affairs. At this juncture the president assumed that the constitution gave him the power of nominating and maintaining in office any ministers he might consider fitting persons for the purpose, and that congress had no right of interference in the matter. The chambers were now only waiting for a suitable opportunity to assert their authority. In 1890 it was stated that President Balmaceda had determined to nominate and cause to be elected as his successor at the expiration of his term of office in 1891 one of his own personal friends. This question of the election of another president brought matters to a head, and congress refused to vote supplies to carry on the government. To avoid trouble Balmaceda entered into a compromise with congress, and agreed to nominate a ministry to their liking on condition that the supplies for 1890 were voted. This cabinet, however, was of short duration, and resigned when the ministers understood the full amount of friction between the president and congress. Balmaceda then nominated a ministry not in accord with the views of congress under Señor Claudio Vícuca, whom it was no secret that Balmaceda intended to be his successor in the presidential chair, and, to prevent any expression of opinion upon his conduct in the matter, he refrained from summoning an extraordinary session of the legislature for the discussion of the estimates of revenue and expenditure for 1891. When the 1st of January 1891 arrived, the president published a decree ordering the Office of the Public Estimator, and the budget of 1890 would be considered the official budget for 1891. This act was illegal and beyond the attributes of the executive power. As a protest against the action of President Balmaceda, the vice-president of the senate, Señor Waldo Silva, and the president of the chamber of deputies, Señor Ramon Barros Luco, issued a proclamation appointing Captain Jorge Montt in command of the squadron, and stating that the navy could not recognize the authority of Balmaceda so long as he did not administer public affairs in accordance with the constitutional law of Chile. The majority of the members of the chambers sided with this movement, and on the 7th of January Señores Waldo Silva, Barros Luco and a number of senators and deputies embarked on board the Chilean warship "Banco Encalada," accompanied by the "Esmeralda" and "O'Higgins" and other vessels, sailing out of Valparaiso harbour and proceeding northwards to Tarapaca to organize armed resistance against the president (see CHILEAN CIVIL WAR). It was not alone this action of Balmaceda in connexion with congress that brought about the other effect, for he had alienated the sympathy of the aristocratic classes of Chile by his parsimony and vanity and ambition. The oligarchy composed of the great landowners have always been an important factor in the political life of the republic; when President Balmaceda found that he was not a persona grata to this circle he determined to endeavour to govern without their support, and to bring into the administration a set of men who had no traditions and with whom his personality would be all-powerful. The Clerical influence was also thrown against him in consequence of his radical ideas in respect of Church matters.

Immediately on the outbreak of the revolution President Balmaceda published a decree declaring Montt and his companions to be traitors, and without delay organized an army of some 40,000 men for the suppression of the insurrectionary movement. While both sides were preparing for extremities, Balmaceda administered the government under dictatorial powers with a congress of his own nomination. In June 1891 he ordered the presidential election to be held, and Señor Claudio Vicuña was duly declared chosen as president of the republic for the next four years. In September 1891 the resources of Balmaceda were running short on account of the heavy military expenses, and he determined to dispose of the reserve of silver bullion accumulated in the vaults of the Casa de Moneda in accordance with the terms of the law for the conversion of the note issue. The silver was conveyed abroad in a British man-of-war, and disposed of partly for the purchase of a fast steamer to be fitted as an auxiliary cruiser and partly in payment for other kinds of war material.
The organization of the revolutionary forces went on slowly. Much difficulty was experienced in obtaining the necessary arms and ammunition. A supply of rifles was bought in the United States, and embarked on board the "Itata," a Chilean vessel in the service of the rebels. The United States authorities refused to allow this steamer to leave San Diego, and a guard was stationed on the ship. The "Itata," however, slipped away and made for the Chilean coast, carrying with her the representatives of the United States. A fast cruiser was immediately sent in pursuit, but only succeeded in overhauling the rebel ship after she was at her destination. The "Itata" was then forced to return to San Diego without landing her cargo for the insurgents. The necessary arms and ammunition were arranged for in Europe; they were shipped in a British vessel, and transferred to a Chilean steamer at Fortune Bay, in Tierra del Fuego, close to the Straits of Magellan and the Falkland Islands, and thence carried to Iquique, where they were safely disembarked early in July 1891. A force of 10,000 men was now raised by the junta of the revolution, and preparations were rapidly pushed forward for a move to the south with the object of attacking Valparaiso and Santiago. Early in April a portion of the revolutionary squadron, comprising the "Blanco Encalada" and other ships, was sent to the southward for reconnoitring purposes and put into the port of Caldera. During the night of the 23rd of April, and whilst the "Blanco Encalada" was lying quietly at anchor, a torpedo boat called the "Almirante Lynch," belonging to the Balmaceda faction, steamed into the bay of Caldera and discharged a torpedo at the rebel ship. The "Blanco Encalada" sank in a few minutes and 300 of her crew perished.

In the middle of August 1891 the rebel forces were embarked at Iquique (where a provisional government under Captain Jorje Montt had been set up), numbering in all about 9000 men, and sailed for the south. On the 20th of August the congressist army was disembarked at Quinteros, about 20 m. north of Valparaiso, and marched to Concon, where the Balmacedists were entrenched. A severe fight ensued, in which the troops of President Balmaceda were defeated with heavy loss. This reverse roused the worst passions of the president, and he ordered the arrest and imprisonment of all persons suspected of sympathy with the revolutionary cause. The population generally were, however, distinctly antagonistic to Balmaceda; and this feeling had become accentuated since the 17th of August 1891, on which date he had ordered the execution of a number of youths belonging to the military college at San Lorenzo on a charge of seditionous practices. The shooting of these boys created a feeling of horror throughout the country, and a sensation of uncertainty as to what measures of severity might not be practised in the future if Balmaceda won the day. After the victory at Concon the insurgent army, under command of General Campos, marched in a southerly direction towards Viña del Mar, and thence to Placilla, where the final struggle in the conflict took place. Balmaceda's generals Barboa and Alcérca had here massed their troops in a strong position. The battle, on the 28th of August, resulted in victory for the rebels. Both the Balmacedist generals were killed and Valparaiso was at once occupied. Three days later the victorious insurgents entered Santiago and assumed the government of the republic. After the battle of Placilla it was clear to President Balmaceda that he could no longer hope to find a sufficient strength amongst his adherents to maintain himself in power, and in view of the rapid approach of the rebel army he abandoned his official duties to seek an asylum in the Argentine legation. The president remained concealed in this retreat until the 18th of September. On the evening of that date, when the term for which he had been elected president of the republic terminated, he committed suicide by shooting himself. The excuse for this act, put forward in letters written shortly before his end, was that he did not believe the conquerors would give him an impartial trial. The death of Balmaceda finished all cause of contention in Chile, and was the closing act of the most severe and bloodiest struggle that country had ever witnessed. In the various engagements throughout the conflict more than 10,000 lives were lost, and the joint expenditure of the two governments on military preparations and the purchase of war material exceeded $10,000,000 sterling.

An unfortunate occurrence soon after the close of the revolution brought strained relations for a short period between the governments of the United States and Chile. A number of men of the U.S.S. "Baltimore" having been given liberty on shore, an argument arose between some of them and a group of Chilean sailors in a drinking den in Valparaiso. Words led to blows. The Americans were badly handled, one of their number being killed and others severely hurt. The United States government characterized the affair as an outrage, demanding an indemnity as satisfaction. The Chilean authorities demurred at this attitude, and attempted to argue the matter. James G. Blaine, then secretary of state, refused peremptorily to listen to any explanations. In the end Chile paid an indemnity of $75,000 as asked, but the affair left bad feeling in its train.

The close of the revolution against Balmaceda left the government of Chile in the hands of the junta under whose guidance the military and naval operations had been organized. Jorje Montt had borne the head of this revolutionary government from the time of the provisional government when the administration of the country changed hands after the victory of the Congressional party. An election was now immediately ordered for the choice of a president of the republic and for representatives in the senate and chamber of deputies. Admiral Montt, as head of the executive power, stanchly refused to allow official influence to be brought to bear in any way in the presidential campaign. The great majority of the voters, however, required no pressure to decide who was in their opinion the man most fitted to administer the affairs of the republic. For the first time in the history of Chile a perfectly free election was held, and Admiral Montt was duly chosen by a nearly unanimous vote to be chief magistrate for the constitutional term of five years. The senate and chamber of deputies were formally constituted in due course, and the government of the republic resumed normal conditions of existence. The new president showed admirable tact in dealing with the difficult problem he was called upon to face. Party feeling still ran high between the partisans of the two sides of the recent conflict. Admiral Montt took the view that it was politic and just to let bygones be bygones, and he acted accordingly by this principle in all administrative measures in connexion with the supporters of the late President Balmaceda. Early in 1892 an amnesty was granted to the officers of the Balmaceda régime, and they were freely permitted to return to Chile without any attempt being made to molest them. The first political act of national importance of the new government was the grant of control to the municipalities, which hitherto had possessed little power to direct local affairs, and were not even permitted to dispose of the municipal revenues to any important amount without first obtaining the consent of the central government. Almost absolute power was now given these corporations to manage their own concerns, and the organization of the police was placed in their hands; at a later period, however, it was found necessary to modify this latter condition.

President Montt next turned his attention towards the question of how best to repair the damage occasioned to the country by eight months of civil war. The plan of public works authorized in 1887 was reconsidered, and the construction of portions of the various undertakings recommenced. The army and navy were reorganized. Additional instructors were brought from Germany, and all arms of the military service were placed on a thoroughly efficient footing in matters of drill and discipline. Several new and powerful cruisers were added to the navy, and the internal economy of this branch of the national defence was thoroughly inspected and many defects were remedied. President Montt then took in hand the question of a reform of the currency, the abolition of inconvertible paper money, and the re-establishment of a gold basis as the monetary standard of the republic. This reform of the currency became the keynote of the president's policy during the remainder of
his term of office. Great opposition was raised by the representatives of the debtor class in congress to the suppression of the inconvertible paper money, but in the end President Montt carried the day, and on the 11th of February 1895 a measure finally became law establishing a gold currency as the only legal tender in Chile. In July 1896 the Conversion Act was put in force, a dollar of 18d. being the monetary unit adopted. In 1895 relations with the neighbouring republic of Argentina began to become somewhat strained in regard to the interpretation of the treaty concerning the boundary between the two countries. The treaties of 1881, 1883 and 1895 left doubts in the minds of both Chileans and Argentines as to the position of the frontier line. On the 17th of April 1896 another protocol was drawn up, by which the contending parties agreed to submit any differences to the arbitration of Great Britain, at the instance of one or both governments. President Montt had now fulfilled his term of office, and on the 18th of September 1896 he handed over the presidential power to his successor, Señor Federico Errázuriz, who had been duly elected in the month of June previously.

The election for the position of president of the republic was closely contested in 1896 between Señor Errázuriz and Señor Reyes, and ended in the triumph of the former candidate by the narrow majority of one vote. The father of the new president had been chief magistrate of Chile from 1871 to 1876, and his administration had been one of the best the country had ever enjoyed; his son had therefore traditions to uphold in the post he was now called upon to fill. At the beginning of 1897 the public attention was absorbed by foreign political questions. The problems to be solved were the frontier difficulty with Argentina, the question of the possession of Tacna and Arica with Peru, and the necessity of fulfilling the obligation contracted with Bolivia to give that country a seaport on the Pacific coast. The treaty made in 1896 with the Argentine government, referring to the arbitration of disputed points concerning the boundary, became practically for the moment a dead letter, and both Argentines and Chileans began to talk openly of an appeal to arms to settle the matter once and for all. The governments of both countries began to purchase large supplies of war material, and generally to make preparations for a possible conflict. In these circumstances no final settlement with Peru and Bolivia was possible, the authorities of those republics holding back to see the issue of the Chile-Argentine dispute, and Chile being in no position at the time to insist on any terms being arranged. So matters drifted until the beginning of 1898. In July of that year the crisis reached an acute stage. Both Chile and Argentina put forward certain pretensions to territory in the Atacama district to the north, and also to a section of Patagonia in the south. Neither side would give way, nor was any disposition exhibited to refer the matter to arbitration under the protocol of 1896. The cry of an acute financial crisis emanating from the fear of war with Argentina was now raised in Chile. The president was advised that the only way of averting the financial ruin of the banking institutions of the republic was to suspend the payments of the government and the national and treasury convertible notes to the banks. Señor Errázuriz weakly gave way, and a decree was promulgated placing the currency once more on an inconvertible paper money basis until 1902. In August of 1898 the Chilean government determined to insist upon the terms of the protocol of 1896 being acted upon, and intimated to Argentina that they demanded the fulfilment of the clause relating to arbitration on disputed points. This was practically an ultimatum, and a refusal on the part of the Argentine government to comply with the terms of the 1896 agreement meant a declaration of war by Chile. For a few days the issue hung in the balance, and then the Argentine government accepted the provisions made in 1896 for arbitration. The dispute concerning the Atacama district was submitted to an arbitration tribunal, consisting of the representative of the United States in Argentina, assisted by one Argentine and one Chilean commissioner. This tribunal, after due investigation, gave their decision in April 1899, and the verdict was accepted unreservedly by both governments. The dispute regarding the Patagonian territory was submitted to the arbitration of Great Britain, and a commission consisting of Lord Macnaghten, Sir John Ardagh and Sir T. H. Holdich—was appointed in 1899 to hear the case.

The Argentine difficulty was ended, but Chile still had to find a settlement with Peru and Bolivia. The treaty made with the former country in 1893 was not ratified, as it was thought to concede too much to Peru, and the subsequent ad referendum treaty was rejected on account of Peru claiming that only Peruvians, and not all residents, should have the right to vote in the plebiscite to be taken by the terms of the treaty of 1883 for the possession of Tacna and Arica. By the terms of the armistice of 1883 between Chile and Bolivia, a three years' notice had to be given by either government wishing to denounced that agreement. By the protocol of 1895 Chile agreed to give to Bolivia the port of Arica, or some other suitable position on the seaboard. On these lines a settlement was proposed. Vitor, standing-place a little to the south of Arica, was offered by the Chilean government to Bolivia, but refused as not complying with the conditions stated in the protocol of 1895; the Bolivians furthermore preferred to wait and see if Arica was finally ceded by Peru to Chile, and if so to claim the fulfilment of the terms of the protocol.

After the accession to office of President Errázuriz there was no stability of any ministry. Political parties in congress were so evenly balanced and so subdivided into groups that a vote against the ministry was easy to obtain, and the resignation of the cabinet immediately followed in accordance with the so-called parliamentary system in vogue in Chile. The president of the republic has no power to dissolve the chambers, to endeavour to remedy the evil by one or another political party obtaining a substantial working majority, but must wait to see the results of the triennial elections. As a consequence of these conditions, Conservative, Liberal and coalition ministries held office at short intervals. These unsettled political circumstances checked any continuity of policy, and tended to block the passage of all useful legislation to help forward the economic development of the country and inhabitants; on the other hand, the financial situation was better by the end of 1899 than in the previous year, since all proposals for a fresh paper issue had been vetoed; and the elections for congress and municipal office at the opening of 1900 returned a majority favourable to a stable currency policy.

In September 1900 a fresh outbreak of hostile feeling against Chile was created in Argentina by a note addressed by the Chilean government to Bolivia, intimating that Chile was no longer inclined to hand over the port of Arica or any other port on the Pacific, but considered the time ripe for a final settlement of the questions connected with the Chilean occupation of Bolivian territory, which had now been outstanding for sixteen years. The foreign policy of Chile, as indicated by this note, was considered by Argentina to be grasping and unconciliatory, and there was a resolution for the formation of an anti-Chilean South American federation. Chile disclaimed any aggressive intentions; but in December the Bolivian congress declined to relinquish their claim to a port, and refused to conclude a definite treaty of peace. The year 1901 closed with a frontier incident between Chile and Argentina in the disputed territory of Ultima Esperanza, where some Argentine colonists were ejected by Chilean police; but both governments signed protocols agreeing not to take aggressive action in consequence.

At the opening of 1901 the country was chiefly interested in the forthcoming presidential election, for which the candidates were Don Pedro Montt (Conservative and Clerical) and Señor German Riesco (Liberal). The relations between President Errázuriz and congress became rather strained, owing to the former's inclination to retain in office a ministry on which congress had passed a vote of censure; but Errázuriz had been in ill-health for more than a year, and on the 1st of May he resigned, and died in July. At the ensuing election Riesco was elected president. The attitude of Chile
towards the Pan-American Congress at Mexico became a matter of interest in the autumn, particularly in connexion with the proposal for compulsory arbitration between all American governments. The Chilean government made it quite clear that they would withdraw from the congress if this proposal was meant to be retroactive; and their unyielding attitude testified to the apprehensions felt by Chile concerning United States interference. In October the Chilean government announced that the contemplated conversion scheme, for which gold had been accumulated, would be postponed for two years (till October 1903), the gold being held as a reserve fund pending the result of the arbitration over the Argentine frontier. This was generally considered to be a reasonable and statesmanlike course. Unfortunately, a recurrence of the excitement over the boundary dispute was occasioned by the irritation created in Argentina by the fact, that pending a decision, Chile was constructing roads in the disputed territory. During December 1902 relations were exceedingly strained, and troops were called out on both sides. But at the end of the month it was agreed to leave the question to the British arbitrators, and the latter decided to send one of their number, Sir T. H. Holdich, to examine the territory.

The survey occupied some eight months, and it was not until the autumn that Sir T. H. Holdich returned to England to make his report. The difficulty of ascertaining the true line of the watershed had been very great, but the result was eminently successful. The award of King Edward was signed on the 20th of November 1902, and both parties to the litigation were satisfied. In order that future disputes might be amicably settled, a treaty was signed by which it was agreed that any question that might arise should be submitted to the arbitration of Great Britain or in default of that power to the Swiss Confederation. The removal of this source of irritation and the restoration of friendly relations between the two republics was a great relief to the finance of Chile. Had it been the case that the political instability of the country, the effects of the diminution of expenditure on military and naval preparations would have effected a rapid improvement in its financial position. The constant change of ministry (there being no stable majority in the congress) prevented during 1903 any settled policy, or that confidence in the government which is the basis of commercial prosperity. In 1904, however, both trade and revenue showed signs of improvement, and the sale of the warships "Esmeralda" and "Chambuco" for £1,000,000 furnished a surplus, which was devoted to the improvement of the port of Valparaiso. This was the beginning of a period of steady industrial growth and development. The settlement of the long outstanding dispute with Bolivia in a treaty of peace signed on the 17th of October 1905 was very advantageous to both countries. By this treaty Bolivia ceded all claims to a seaport and strip of the coast, on condition that Chile constructed at her own charges a railway to Llipaya from the port of Arica, giving at the same time to Bolivia free transit across Chilean territory to the sea. A cash indemnity of £500,000 was also paid, and certain stipulations were made with regard to the construction of other railways giving access from Chile to the Bolivian interior.

The prosperity of Chile was to suffer a rude shock. On the 17th of August 1906 a terrible earthquake visited Valparaiso and the surrounding districts. The town of Valparaiso was almost entirely destroyed, while Santiago and other towns were severely shaken and suffered much damage. It was estimated that about 3000 persons were killed, a still larger number injured, and at least 100,000 rendered homeless. The loss of property was enormous. The fire which broke out after the earthquake shock had subsided added to the horror of the catastrophe. Measures were, however, promptly taken for succouring the people, who had been driven from their homes, and the task of restoration was vigorously taken in hand. Before the end of the year the rebuilding of the city was rapidly progressing.

In 1906 Señor Pedro Montt was elected president and entered upon his office on the 17th of September. The personality of the president, however, had become of much less importance in modern Chile than in earlier days. Up to 1870 the government was in the hands of a small oligarchy of Santiago families, but the president enjoyed large powers of initiative. Nowadays the congress has virtually absorbed the executive power, with the result that the cabinet is often changed many times in one year. This prevents indeed any continuity of policy, for the majority in congress is perpetually fluctuating, and ministerial crises rapidly follow one another. Chile, however, except in the Balsacmedist civil war, is happily distinguished by its freedom from revolution and serious political unrest. Its history in this respect is in marked contrast to that of the neighbouring South American states. The completion of the Trans-Andean railway between Valparaiso and Buenos Aires was bound to be of immense commercial and industrial value; and eventually the making of a longitudinal railway route unifying the nitrate province of the north with Santiago, and Santiago with Puerto Montt in the distant south, opened up further important points. The most important of the communications, binding together the different provinces forming the long narrow strip of territory stretching along more than 2000 m. of the Pacific littoral, could only be looked forward to, both politically and economically, as an inestimable benefit to the country.

BIBLIOGRAPHY.—General History.—The most valuable authority is D. Barros Arana’s Historia general de Chile (15 vols., Santiago, 1884), from the earliest days up to 1830. Smaller handbooks covering the whole period are: A. U. Hancock, a History of Chile (Chicago, 1895), the only general history in English, and containing a bibliography; Caspar Toro, Compendio de la historia de Chile (Santiago, 1879), a good clear abstract of Chilean history; and F. Valdes Vergara, Historia de Chile (Valparaiso, 1898), written primarily for schools, but containing useful sketches of leading figures in Chilean history.

Works on Special Periods.—Colonial Period: M. L. Amunátei, Descubrimiento y conquista de Chile (Santiago, 1885), a valuable detailed account of the Spanish conquest; by same author, Las campañas de Chile (Santiago, 1889), another useful description of the evils of the Spanish colonial system; Horacio Lara, Cronica de la Araucania (Santiago, 1889), a history of the Araucanian Indians fight up to recent dates; Abbé Eyraud, Histoire de l’Arabie (Paris, 1888), a valuable work on the position of the Church during the colonial period. Perez García’s Historia del reino de Chile (Santiago, 1900), an old history by a Spanish officer written about 1780, and Molina’s Historia de Chile (15 vols., 1828-39) is a translation from the French. Useful material for research exists in J. T. Medina’s Coleccion de documentos para la historia de Chile (Santiago, 1888), a collection of despatches and official documents; his Cosas de la colonia (6 vols., 1880), an account of the constitution of the government; his Historia del pueblo chileno (2 vols., Santiago, 1886), a translation of Philip’s life in the colonial period; and Historiadores de Chile (21 vols., Santiago, 1861), a collection of ancient chronicles and official documents up to the early part of the 17th century.

Revolutionary Period.—A. Bolland, Los primeros Asambleas nacionales (Santiago, 1890), an account of the struggles in the first national assemblies: A. Valdes, Revolucion Chilena y compañías de la independencia (Santiago, 1888), an account of the early fighting during the first revolutionary leaders; W. R. Filling, Emancipation of South America (London, 1863), a translation of B. Mitre’s life of San Martin, describing the fighting in the wars of independence; Lord Cochrane, Narrative of Services in Chile, Peru and Brazil (London, 1831), an account of the fighting during this battle describing the hero who helped to secure the expulsion of the Spaniards; B. Vicuna Mackenna, Vida de O’Higgins (Santiago, 1882), giving a useful account of the revolutionary struggle and the main actors; and the Historical Works of the Chilean Senate’s Historia de Chile, a collection of essays on the early republican history by various writers.

Later History.—R. Sotomayor Valdes, Historia de Chile, 1831—1871, a detailed account of the period (Santiago, 1875); the same author’s Campana de ejercicios militares (1837—1871), describing the fighting of the first Peruvian War; B. Vicuna Mackenna, D. Diego Porales (Valparaiso, 1863), a good account of the life and time of Portales, the famous minister of the Conservative party; H. F. Escalona, Historia de la revolucion constituyente 1859—1880 (Santiago, 1889), an account of the revolution at the end of Montt’s presidency; F. Fonch, Chile en der Gegenwart (Berlin, 1870), a description of Chile at the time; Statement on Behalf of Chile in the House of Commons in regard to the Hawaiian Claims (London, 1901—1902); Sir Thomas Holdich, Countries of the King’s Award (1904); Beltran y Rospido, Los Pueblos hispano-americans en el siglo XX. (Madrid, 1904); P. F. Martin, Through Five Republics of South America (London, 1905); D. G. F. Scott Elliot, Chile (London, 1907); Sir W. M.
CHILEAN CIVIL WAR—CHILE-PERUVIAN WAR

Conway, Aconcagua y Tierra del Fuego (London, 1902); “Chile: Argentine Arbitration” in the Geog. Journal (January 1903); C. M. Pepper, Panama to Patagonia (London, 1907); C. E. Akers, History of South America, 1830-1904 (London, 1904); M. Hume, Lecture on the Republic of Chile (London, 1902).

CHILEAN CIVIL WAR (1891). The Chilean civil war grew out of political dissensions between the president of Chile, J. M. Balmaceda, and his congress (see CHILE: History), and began in January 1891. On the 6th, at Valparaíso, the political leaders of the Congressional party went on board the ironclad “Blanco Encalada,” and Captain Jorje Montt of that vessel hoisted a broad pennant as commander of the Congressional fleet. Preparations had long been made for the naval pronunciamiento, and in the end few vessels of the Chilean navy adhered to the cause of the “dictator” Balmaceda. But amongst these were two new and fast torpedo gunboats, “Almirante Condell” and “Almirante Lynch,” and in European dockyards (incomplete) lay the most powerful vessel of the navy, the “Arturo Prat,” and two fast cruisers. If these were secured by the Balmacedists the naval supremacy of the congress would be seriously challenged. For the present, and without prejudice to the future, command of the sea was held by Montt’s squadron (January).

The rank and file of the army remained faithful to the executive, and thus in the early part of the war the “Gobernistas,” speaking broadly, possessed an army without a fleet, the congress a fleet without an army. Balmaceda hoped to create a navy; the congress took steps to recruit an army by taking its sympathizers on board the fleet. The first shot was fired, on the 16th of January, by the “Blanco” at the Valparaíso batteries, and landing parties from the warships engaged small parties of government troops at various places during January and February. The dictator’s principal forces were stationed in and about Iquique, Coquimbo, Valparaíso, Santiago, and Concepción. The troops at Iquique and Coquimbo were necessarily isolated from the rest and from each other, and military operations began, as in the campaign of 1879 in this quarter, with a naval descent upon Pisagua followed by an advance inland to Dolores. The Congressional forces failed at first to make good their footing (16th-23rd of January), but, though defeated in two or three actions, they brought off many recruits and a quantity of munitions of war. On the 26th they retook Pisagua, and on the 15th of February the Balmacedist commander, Eulalio Robles, who offered battle in the expectation of receiving reinforcements from Tacna, was completely defeated on the old battlefield of San Francisco. Robles fell back along the railway, called up troops from Iquique, and beat the invaders at Haura on the 17th, but Iquique in the meanwhile fell to the Congressional fleet on the 16th. The Pisagua line of operations was at once abandoned, and the military forces of the congress were moved by sea to Iquique, whence, under the command of Colonel Estanislao Del Canto, they started inland. The battle of Pozo Almonte, fought on the 7th of March, was desperately contested, but Del Canto was superior in numbers, and Robles was killed and his army dispersed. After this the Balmacedist troops in the north made up a strong force, partly from those who came into Peru, others into Bolivia, and one column made a laborious retreat from Calama to Santiago, in the course of which it twice crossed the main chain of the Andes.

The Congressional Junta de Gobierno now established in Iquique prosecuted the war vigorously, and by the end of April the whole country was in the hands of the “rebels” from the Peruvian border to the outposts of the Balmacedists at Coquimbo and La Serena. The Junta now began the formation of a properly organized army for the next campaign, which, it was believed universally on both sides, would be directed against Coquimbo. But in a few months the arrival of the new ships from Europe would reopen the struggle for command of the sea; the torpedoeras “Condell” and “Lynch” had already weakened the Congressional squadron severely by sinking the “Blanco Encalada” in Caldera Bay (23rd of April), and the Congressional party could no longer aim at a methodical conquest of successive provinces, but was compelled to attempt to crush the dictator at a blow.

Where this blow was to fall was not decided up to the last moment, but the instrument which was to deliver it was prepared with all the care possible under the circumstances. Del Canto was made commander-in-chief, and an ex-Prussian officer, Emil Körner, chief of staff. The army was organized in three brigades of all arms, at Iquique, Caldera and Vallenar. Körner super-intended the training of the men, gave instruction in tactics to the officers, caused maps to be prepared, and in general took every precaution that his experience could suggest to ensure success. Del Canto was himself no mere figurehead, but a thoroughly capable leader who had distinguished himself at Tacna (1880) and Miraflores (1881), as well as in the present war. The men were enthusiastic, and the officers unusually numerous. The artillery was fair, the cavalry good, and the train and auxiliary services well organized. About one-third of the infantry were armed with the (Männlicher) magazine rifle, which now made its first appearance in war, the remainder had the Gras and other breech-loaders, which were also the armament of the dictator’s infantry. Balmaceda could only wait upon events, but he prepared his forces as best he was able, and his torpederas constantly harassed the Congressional navy. By the end of July Del Canto and Körner had done their work as well as time permitted, and early in August the troops prepared to embark, not for Coquimbo, but for Valparaíso itself.

The expedition by sea was admirably managed, and Quinteros, N. of Valparaíso and not many miles out of range of its batteries, was occupied on the 20th of August 1891. Balmaceda was surprised, but acted promptly. The first battle was fought on the Aconcagua at Concon on the 21st. The eager infantry of the Congressional army forced the passage of the river and stormed the heights held by the Gobernistas, capturing 36 guns. The killed and wounded of the Balmacedists numbered 1600, and nearly all the prisoners, about 1500 men, enrolled themselves in the rebel army, which thus more than made good its loss of 1000 killed and wounded. The victors pressed on towards Valparaíso, but were soon brought up by the strongly fortified position of the Balmacedist general Barbosa at Viña del Mar, whence Balmaceda hurried up all available troops from Valparaíso and Santiago, and even from Concepción. Del Canto and Körner now resolved on a daring step. Supplies of all kinds were brought up from Quinteros to the front, and on the 24th of August the army abandoned its line of communications and marched inland. The flank march was conducted with great skill, little opposition was encountered, and the rebels finally appeared to the southeast of Valparaíso. Here, on the 28th, took place the decisive battle of La Placilla. Concon had been perhaps little more than the destruction of an isolated corps; the second battle was a fair trial of strength, for Barbosa was well prepared, and had under his command the greater part of the existing forces of the dictator. But the splendid fighting qualities of the Congressional troops and the superior generalship of their leaders prevailed in the end over every obstacle. The government army was practically annihilated, 941 men were killed, including Barbosa and his second in command, and 2849 wounded. The Congressional army lost over 1800 men. Valparaíso was occupied the same evening and Santiago soon afterwards. There was no further fighting, for so great was the effect of the battles of Concon and La Placilla that even the Coquimbo troops surrendered without firing a shot.

CHILE-PERUVIAN WAR (1879-1882). The proximate cause of this war was the seizure, by the authorities of Bolivia, of the effects of the Chilean Nitrate Company at Antofagasta, then part of the Bolivian province of Atacama. The first act of
hostility was the despatch of 500 soldiers to protect Chilean interests at Antofagasta. This force, under Colonel Sotomayor, landed and marched inland; the only resistance encountered was at Calama on the river Loa, where a handful of newly raised militia was routed (23rd March 1879). About the same time, Chilean warships occupied Cobija and Tocapillas, and Sotomayor, after his victory at Calama, marched to the latter port. Bolivia had declared war on the 1st of March, but Peru not till the 7th of April: this delay gave the Chileans time to occupy every port on the Bolivian coast. Thus the Chilean admiral was able to proceed at once to the blockade of the southern ports of Peru, and in particular Iquique, where there took place the first naval action of the war. On the 21st of April the Chilean sloop "Esméralda" and the gunboat "Covadonga"—both small and weak—engaged the Peruvian heavy ironclad "Huascar" and "Independencia"; after a hot fight the "Huascar" under Miguel Grau sank the "Esméralda" under Arturo Prat, who was killed, but Carlos Condell in the "Covadonga" manoeuvred the "Independencia" around and shelled her into a complete wreck. When the Chileans now gave up the blockade and concentrated all their efforts on the destruction of the "Huascar," while the allies organised a field army in the neighbourhood of Tacna and a large Chilean force assembled at Antofagasta.

On the 8th of October 1879 the "Huascar" was brought to action off Angamos by the "Blanco Encalada," and the "Almirante Cochrane." Grau was outmatched as hopelessly and made as brave a fight as Prat at Iquique. Early in the action a shot destroyed the Peruvian's conning tower, killing Grau and his staff, and another entered her turret, killing the flag captain and nearly all the crew of the turret guns. When the "Huascar" finally surrendered she had but one gun left in action, her fourth commander and three-quarters of her crew were killed and wounded, and the steering-gear had been shot away. The Peruvian navy had now ceased to exist. The Chileans resumed the blockade and five operations were soon undertaken. The whole force of the allies was about 20,000 men, scattered along the seaboard of Peru. The Chileans on the other hand had a striking force of 16,000 men in the neighbourhood of Antofagasta, and of this nearly half was embarked for Pisagua on the 26th of October. The expeditionary force landed, in the face of considerable opposition, on the 2nd of November, and captured Pisagua. From Pisagua the Peruvians and Bolivians fell back along the railway to their reinforcements, and when some 10,000 men had been collected they moved forward to attack the Chilean position of San Francisco near Dolores station (10th November). In the end the Chileans were victorious, but their only material gain was the possession of Iquique and the retreat of the allies, who fell back inland towards Tarapacá. The tardy pursuit of the Chileans ended in the battle of Tarapacá on the 27th. In this the allies were at first surprised, but, rapidly recovering themselves, they charged the enemy, and after a murderous fight, in which many were killed, the Chileans were driven back in complete defeat. For some inexplicable reason the allies made no use of their victory, continued to retreat and left the Chileans in complete possession of the Tarapacá region. With this the campaign of 1879 ended. Chile had taken possession of the Bolivian seaboard and of the Peruvian province of Tarapacá, and had destroyed the hostile navy.

The object of the Chileans in the second campaign was the province of Tacna and the field force of the allies at Tacna and Arica. The invasion was again carried out by sea, and 12,000 Chileans were landed at Pacoche (Yb), far to the N. of Arica. Careful preparations were made for a desert march, and on the 12th of March 1880, the advanced corps started inland for Moquegua, which was occupied on the 20th. Near Moquegua the Peruvians, some 2000 strong, took up an unusually strong position in the defile of Cuesta de los Angeles. But the great numerical superiority of the assailants enabled them to turn the flank and press the front of the Peruvian position, and after a severe struggle the defence collapsed (March 22nd). In April the army began its advance southward from Moquegua to Tacna, while the Chilean warships engaged in a series of minor naval operations in and about the bay of Callao. Arica was also watched, and the blockade was extended north of Lima. The land campaign had ere this culminated in the battle of Tacna (May 26th), in which the Chileans attacked in first in several disconnected bodies, and suffered severely until all their forces came on the field. This battle, the Chileans having resolved to carry out an advance under General Narciso Campero, the new president of Bolivia, of nearly 3000 men, and the Chileans, commanded by Manuel Baquedano, lost 2000 out of 8500 on the field. The defeated army was compelled to disband, and it only remained for the Chileans to march on Arica, lose 2000 more, and take the surrender of the town. The next move was against the high-range guns, on the 7th of June a general assault was made, and before nightfall the whole of the defences were in the hands of the Chileans. Their second campaign had given them entire possession of another territory of some importance (Edén and Deserto) (from which Chilean occupation was maintained). With Tacna and Arica in one hand, and the Peruvian coast and the province of Moquegua (23rd January 1880), the Chileans now had a line of position consisting of two distinct positions, Chorrillos and Miraflores, the latter being about 4000 yds. outside Lima. The first line of defence was attacked by Baquedano on the 13th of January 1881. Reconnaissances proved that the line could not be turned, and the battle was a pure frontal attack. The defenders had 22,000 men in the lines, the Chileans engaged about 24,000. The battle of Chorrillos ended in the complete defeat of the Peruvians, less than a third of whom escaped. Those who fell back behind the Miraflores defences. The Chileans lost over 3000 killed and wounded. Two days later took place a battle of Miraflores (January 15th). Here the defences were very strong, and the action began with a daring counter-attack by some Peruvians. Neither party had intended to fight a battle, for negotiations were in progress, and the Chileans were sure that the British would become general. Its result was to give Chile before the complete dissolution of the defending army. Lima, incapable of defence, was occupied by the invaders on the 17th, and the 18thCallao surrendered. The resistance of the Peruvians was to beeffected by the size of their forces that day (February 8th). The original site, known as Chililn Viejo, forms a suburb of the metropolis. The hot sulphur springs of Chililn, which were discovered in 1795, are about 45 m. E.S.E. They issue from the flanks of the "Volcan Viejo," about 7000 ft. above sea-level. The highest temperature of the water issuing from these springs is a little over 135° C. The principal volcanoes of the Chillán group are the Nevado (9285 ft.) and the Viejo. After a repose of about two centuries the Nevado de Chillán broke out in eruption early in 1861 and caused great destruction. The eruption ceased in 1863, but broke out again in 1864.
obelisk erected at Chilianwalla by the British government preserves the names of those who fell.

CHILLICOTHE, a city and the county-seat of Livingston county, Missouri, U.S.A., situated in the N. part of the state, on the Grand river, about 80 m. N.E. of Kansas City. Pop. (1880) 15,717; (1900) 6905 (538 negroes); (1910) 6265. It is served by the Chicago, Milwaukee & St Paul, the Wabash, and the Chicago, Burlington & Quincy railways. There are various manufactures. Coal and limestone are found in the vicinity, and much live stock is raised, wool and hides being shipped from Chillicothe. Chillicothe was settled about 1830, and the town was laid out in 1837 on land granted directly by the Federal government; it was incorporated in 1855.

CHILLICOTHE, a city and the county-seat of Ross county, Ohio, U.S.A., on the W. bank of the Scioto river, on the Ohio & Erie Canal, about 50 m. S. of Columbus. Pop. (1890) 11,288; (1900) 12,976, of whom 986 were negroes, and 910 were foreign-born; (1910 census) 14,508. Chillicothe is served by the Baltimore & Ohio South-Western (which has railway shops here), and other railways. The city has two parks. There are several ancient mounds in the vicinity. Chillicothe is built on a plain about 30 ft. above the river, in the midst of a fertile agricultural region, and has a large trade in grain and coal, and in manufactures. The value of the factory products increased from $1,615,950 in 1900 to $3,146,890 in 1905, or 94.7 %.

Chillicothe was founded in 1796, and was first incorporated in 1802. In 1800-1803 it was the capital of the North-West Territory, and in 1803-1810 and 1812-1816 the capital of Ohio. Three Indian villages bore the name Chillicothe, each being in turn the chief town of the Chillicothe, one of the four tribal divisions of the Shawnee, in their retreat before the whites; the village near what is now Oldtown in Greene county was destroyed by George Rogers Clark in 1780; that in Miami county, where Piqua is now, was destroyed by Clark in 1782; and the Indian village near the present Chillicothe was destroyed in 1787 by Kentuckians.

See Henry Howe, *Historical Collections of Ohio* (Columbus, 1891).

CHILLYINGHAM, William (1602-1644), English divine and controversialist, was born at Oxford in October 1602. In June 1618 he became a scholar of Trinity College, Oxford, and was made a fellow of his college in June 1623. He had some reputation as a skillful disputant, excelled in mathematics, and gained some credit as a writer of verses. The marriage of Charles L with Henrietta Maria of France had stimulated the propaganda of the Roman Catholic Church, and the Jesuits made the universities their special point of attack. One of them, "John Fisher," who had his sphere at Oxford, succeeded in making a convert of young Chillingworth, and prevailed upon him to go to the Jesuit college at Douai. Influenced, however, by his godfather, Laud, then bishop of London, he resolved to make an impartial inquiry into the claims of the two churches. After a short stay he left Douai in 1631 and returned to Oxford. On grounds of Scripture and reason he at length declared for Protestantism, and wrote in 1634, but did not publish, a refutation of the motives which had led him over to Rome. This paper was lost; the other, on the same subject, was probably written on some other occasion at the request of his friends. He would not, however, take orders. His theological sensitiveness appears in his refusal of a preferment offered to him in 1635 by Sir Thomas Coventry, lord keeper of the great seal. In 1636 he was in difficulty about subscribing the Thirty-nine Articles. As he informed Gilbert Sheldon, then warden of All Souls, in a letter, he was fully resolved on two points—that to say the Fourth Commandment is a law of God appertaining to Christians is false and unlawful, and that the damnable clauses in the Athanasian Creed are most false, and in a high degree presumptuous and schismatical. To subscribe, therefore, he felt would be to "subscribe his own damnation." At this time his principal work was far towards completion. It was undertaken in defence of Dr Christopher Potter, provost of Queen's College in Oxford, who had for some time been carrying on a controversy with a Jesuit known as Edward Knott, but whose real name was Matthias Wilson. Potter had replied in 1633 to Knott's *Charity Mistaken* (1630), and Knott retaliated with *Mercy and Truth*. This work Chillingworth engaged to answer, and in it both the author and the editor hope to bring the public mind, hastily brought out a pamphlet tending to show that Chillingworth was a Socinian who aimed at perverting not only Catholicism but Christianity.

Laud, now archbishop of Canterbury, was not a little solicitous about Chillingworth's reply to Knott, and at his request, as "the young man had given cause why a more watchful eye should be held over him and his writings," it was examined by the vicechancellor of Oxford and two professors of divinity, and published with their approbation in 1637, with the title *The Religion of Protestants a Safe Way to Salvation*. The main argument is a vindication of the sole authority of the Bible in spiritual matters, and of the free right of the individual conscience to interpret it. In the preface Chillingworth expresses his new view about subscription to the articles. "For the Church of England," he there says, "I am persuaded that the constant doctrine of it is so pure and orthodox, that whosoever believes it, and lives according to it, undoubtedly he shall be saved, and that there is no error in it which may necessitate or warrant the rejection of it; and that if any error there be, it is the communion of the Church which is, in my opinion, all intended beyond all questions. His scruples having thus been overcome, he was, in the following year (1638), promoted to the chancellorship of the church of Sarum, with the prebend of Brixworth in Northamptonshire annexed to it. In the great civil struggle he used his pen against the Scots, and was in the king's army at the siege of Gloucester, inventing certain engines for assaulting the town. Shortly afterwards he accompanied Lord Hopton, general of the king's troops in the west, in his march; and, being laid up with illness at Arundel Castle, he was there taken prisoner by the parliamentary forces under Sir William Waller. As he was unable to go to London with the garrison, he was conveyed to Chichester, and died there in January 1644. His last days were harassed by the diatribes of the Puritan preacher, Francis Cheynell.

Besides his principal work, Chillingworth wrote a number of smaller and Jesuit tracts published in the posthumous *Additional Discourses* (1687), and nine of his sermons have been preserved. In politics he was a zealous Royalist, asserting that even the unjust and tyrannous violence of princes may not be resisted, although it might be an inhuman act in terms of the instruction which they persecute you in one city, flee into another. His writings loved simplicity. The *Religion of Protestants* is characterized by much fairness and acuteness of argument, and was commended by Locke as a discipline of "perspicuity and the way of right reasoning. The *Mistaken Character of the Jesuits* was simply brought against him, but his Tiltsפתo thought, "for no other cause but the worthy and successful attempts to make the Christian religion reasonable." His creed, and the whole gist of his argument, is expressed in a single sentence, "I believe that God does not, and therefore that men ought not to, require any more of any man than this, to believe the Scripture to be God's word, and to endeavour to find the true sense of it, and to live according to it." A Life by Rev. R. Birch was prefixed to the 1742 edition of Chillingworth's Works.

CHILE (from *Chile* and *hué*, "part of Chile"), a province of southern Chile, and also the name of a large island off the Chilean coast forming part of the province. The province, area 8593 sq. m., pop. (1895) 77,750, is composed of three groups of islands, the Chilean, Guataecas and Chonos, and extends from the narrow strait of Chacao in 41° 40' S. to the peninsula of Tayota, about 45° 45' S. The population is composed mainly of Indians, distantly related to the tribes of the mainland, and mestizos.

The capital of the province is Ancud or San Carlos, at the north end of the Island of Chiloé, on the sheltered bay of San Carlos, once frequented by whalers. It is the seat of a bishopric; pop. (1905) 3182. Other towns are Castro, the former capital, on the eastern shore of Chiloé, and the oldest town of the island (founded 1666), once the seat of a Jesuit mission, and Melinka on an island of the Guataecas group.

The island of Chiloé, which lies immediately south of the province of Llanquihue, is a continuation of the western Chilean formation, the coast range appearing in the mountainous range of western Chile and the islands extending south along the coast. Between this coast
range and the Andes, the gulls of Chacao, or Ancud and Coquimbo (average width, 30 m.) separate the island from the mainland. Chiloé has an extreme length north to south of about 116 m., and an average width of 25 to 40 m., with an area of about 4700 sq. m. There are several lakes on the island—Chacao, 12 a long, being the largest—and one small river, the Pudeto, in the northern part of the island, is celebrated as the scene of the last engagement in the war for independence, the Spanish retaining possession of Chiloé until 1826.

CHILION, of Sparta, son of Damastes, one of the Seven Sages of Greece, flourished about the beginning of the 6th century B.C. In 560 (or 556) he acted as ephebus, an office which he is even said to have founded. The tradition was that he died of joy on hearing that his son had gained a prize at the Olympic games. According to Chilon, the great virtue of man was prudence, or well-grounded judgment as to future events.

A collection of the sayings attributed to him will be found in F. W. Mullach, *Fragmenta Philosophorum Graecorum*, i. See Herodotus i. 67; Diogenes Laertius i. 68; Pausanias iii. 16, x. 24.

CHILPERIC, the name of two Frankish kings.

Chilperic I. (d. 584) was one of the sons of Clovis I. Immediately after the death of his father in 561 he endeavoured to take possession of the whole kingdom, seized the treasure amassed in the royal palace of Berry, and entered Paris. His brother, however, compelled him to divide the kingdom with them, and Soissons, together with Amiens, Arras, Cambrai, Thérouanne, Tournai and Boulogne, fell to Chilperic’s share, but on the death of Chilperic in 577 his estates were augmented. When his brother Sigebert married Brunhilda, Chilperic also wished to make a brilliant marriage. He had already repudiated his first wife, Audovera, and had then concubined a serving-woman called Fredegond. He accordingly dismissed Fredegond, and married Brunhilda’s sister, Galswintha. But he soon tired of his new partner, and one morning Galswintha was found strangled in her bed. A few days afterwards Chilperic married Fredegond. This murder was the cause of long and bloody wars, interspersed with truces, between Chilperic and Sigebert. In 575 Sigebert was assassinated by Fredegond at the very moment when he had Chilperic at his mercy. Chilperic retrieved his position, took to himself Galswintha and some places in Aquitaine, and forested discord in the kingdom of the east during the minority of Childebert II. One day, however, while returning from the chase to the town of Chelles, Chilperic was stabbed to death. Chilperic may be regarded as the type of Merovingian sovereigns. He was exceedingly anxious to extend the royal authority. He levied numerous imposts, and his fiscal measures provoked a great sedition at Limoges in 579. He wished to bring about the subjection of the church, and to this end sold bishoprics to the highest bidder, annulled the wills made in favour of the bishoprics and abbots, and sought to impose upon his subjects a rationalistic conception of the Trinity. He pretended to some literary culture, and was the author of some halting verse. He even added letters to the Latin alphabet, and wished to have the MSS. rewritten with the new characters. The wrestling of Tours from Austrasia and the seizure of ecclesiastical property provoked the bitter hatred of Gregory of Tours, by whom Chilperic was stigmatized as the Nero and the Herod of his time.

**CHILPERIC II.** (d. 720) was the son of Chilperic II. He became king of Neustria in 715, on which occasion he changed his name from Daniel to Chilperic. At first he was a tool in the hands of Ragenfrid, the mayor of the palace. Charles Martel, however, overthrew Ragenfrid, accepted Chilperic as king of Neustria, and, on the death of Childebert IV., set him over the whole kingdom. The young king died soon afterwards. (C. F.)

**CHILTERN HILLS, or THE CHILTERNs,** a range of chalk hills in England, extending through part of Oxfordshire, Buckinghamshire and Bedfordshire. Running from S.W. to N.E., they form a well-marked escarpment north-westward, while the south-eastern slope is long. The name of Chilterns is applied to the hills between the Thames in the neighbourhood of Goring and the headwaters of its tributary the Lea between Dunstable and Hitchin, the least line between these points being about 57 m. 2 f. long. But these hills are part of a larger chalk system, continuing the line of the White Horse near Wantage, and themselves continued eastward by the East Anglian ridge. The greatest elevation of the Chilterns is found in the centre from Watlington to Tring, where heights from 800 to 850 ft. are frequent. Westward towards the Thames gap the elevation falls away but little, but eastward the East Anglian ridge does not often exceed 300 ft., though it continues the northward escarpment across Hertfordshire. There are several passes through the Chilterns, followed by main roads and railways converging on London, which lies in the basin of which these hills form part of the northern rim. The most remarkable passes are those near Tring, Wendover and Prince’s Risborough, the floors of which are occupied by the gravels of former rivers. The Chilterns were formerly covered with a forest of beech, and there is still a local supply of this wood for the manufacture of chairs and other articles in the neighbourhood of Wycombe.

**CHILTERN HUNDREDS.** An old principle of English parliamentary law declared that a member elected to one hundred could not resign his seat. This rule was a relic of the days when the local gentry had to be compelled to serve in parliament. The only method, therefore, of avoiding the rule came to be by accepting an office of profit from the crown, a statute of 1707 enacting that every member accepting an office of profit from the crown should thereby vacate his seat, but should be capable of re-election, unless the office held was presided over since 1705, or had been otherwise declared to disqualify for a seat in parliament. Amongst the places of profit held by members of the House of Commons in the first half of the 18th century are to be found the names of several crown stewardships, which apparently were not regarded as places of profit under the crown within the meaning of the act of 1707, for no seats were vacated by appointment to them. The first instance of the acceptance of such a stewardship vacating a seat was in 1740, when the house decided that Sir W. W. Wynn, in inheriting the estate of his uncle, in which the stewardship of the lordship and manor of Bromfield and Yale, had ipso facto vacated his seat. On the passing of the Place Act of 1742, the idea of utilizing the appointment to certain crown stewardships (possibly suggested by Sir W. W. Wynn’s case) as a pretext for enabling a member to resign his seat was carried into practice. These nominal stewardships were eight in number, but only two survived to be used in this way in contemporary practice—those of the Chilterns and Northstead; and when a member wished to vacate his seat, he was accordingly spoken of as taking the Chiltern Hundreds.

1. Steward and Bailiff of the Chiltern Hundreds, County Bucks.—In 1763, and was in more or less constant use until 1840, after which it disappeared. They are situated on the Chiltern Hills, and the subdepositions of the bandits, who found shelter within their recesses, became at an early period so alarming that a special officer, known as the steward of the Chiltern Hundreds, was appointed for the protection of the inhabitants of the neighbouring districts. It is doubtful at what date the necessity for such an appointment disappeared, but the three hundreds of Stolc, Burnham and Desborough are still distinguished by the old name. The appointment of steward was first used for parliamen-

tary purposes in cases of several hundred, the common officer of the Hundred, as was the chancellor of the exchequer (and at his discretion to grant or not), and the warrant bestowing on the holder “all wages, fees, allowances and other privileges and pre-eminences.” Up to the 19th century the steward was usually a nominal officer, who was sometimes appointed to the post in 1846 by the chancellor of the exchequer that the Chilterns could not be granted to more than one person in the same day, but this rule has not been strictly adhered to, for on four occasions between 1846 and 1850, two or more stewardships were granted on the same day. The Chilterns might be granted to members whether they had taken the oath or not, or during a recess, though in this case a new writ could not be issued until the House met again. Each new warrant for a stewardship was thus a type of the old writ, and the steward retaining it in his turn until another should be appointed.

2. Steward and Bailiff of the Manor of East Hundred, or Hundred, Berks.—This stewardship was first used for parliamentary purposes about 1763, and was in more or less constant use until 1840, after which it disappeared. This manor comprised 3700 acres, the usual courts were held, and the stewardship was an actual and active office, the duties being executed by a deputy steward. The manor was sold by
public auction in 1823 for £510, but in some manner the crown retained the right of appointing a steward for seventeen years after that date.

3. Steward and Bailiff of the Manor of Northstead, Yorkshire.——This steward was away a party before 1750, but was in lease until 1838. It has no copyhold lands, nor are there any records of manor courts. There are no traces of any profits having ever been derived from the office. It was used for parliamentary purposes in 1844 and subsequently.

4. Steward of the Manor of Hempholne, Yorkshire.——This manor appears to have been of the same nature as that of Northstead. It was in lease until 1835. It was first used for parliamentary purposes in 1849 and was in constant use until 1865. It was sold in 1866.

5. Escheator of Munster.——Escheators were officers commissioned to secure the rights of the crown over property which had legally escheated to it. In Ireland mention is made of escheators as early as 1256. In 1665 the escheatorship of Ireland was split up into four, one for the province, but the duties soon became practically nominal. The escheatorship of Munster was first used for parliamentary purposes in the Irish parliament from 1733 to 1800, and in the united parliament (24 times for Irish seats and once for a Scottish seat) from 1801 to 1820. After 1820 it was discontinued and finally abolished in 1838.

6. Steward of the Manor of Old Shoreham, Sussex.——This manor belonged to the duchy of Cornwall, and it is difficult to understand how it came to be regarded as a crown appointment. It was first used for parliamentary purposes in 1756, and then, occasionally, until 1799, in which year it was sold by the duchy to the duke of Norfolk.

7. Steward of the Manor of Poynings, Sussex.——This manor reverted to the crown on the death of Lord Montague about 1804, but was leased up to about 1835. It was only twice used for parliamentary purposes, in 1841 and 1843.

8. Steward of this Appointment.——This appointment was used in the united parliament three times, for Irish seats only: the last time in 1819.

See parliamentary paper.—Report from the Select Committee on House of Commons (Vocating of Seats) (1844).

CHILWA (incorrectly SHIRWA), a shallow lake in south-east Africa, S.S. of Lake Nyasa, cut by 15° 20' E., and lying between 15° and 15° 35' S. The lake is undergoing a process of desiccation, and in some dry seasons (as in 1879 and 1903) the “open water” is reduced to a number of large pools. Formerly the lake seems to have had an outlet northwards to the Lujenda branch of the Rovuma, but with the sinking of its level it is now separated from the Lujenda by a woody ridge some 30 to 40 ft. above the surrounding plains. There are four islands, the largest rising 200 ft. above the water. The lake was discovered by David Livingstone in 1859 and was by him called Shirwa, from a mishearing of the native name.

CHIMAERA, in Greek mythology, a fire-breathing, malevolent monster resembling a lion in the front, a goat in the middle, and a dragon behind (Hiad, vi. 179), with three heads corresponding. She devastated Caria and Lycia until she was finally slain by Bellerophon (see H. A. Fischer, Bellerophon, 1831). The origin of the myth was the volcanic nature of the soil of Lycia (Pliny, Nat. Hist. ii. 110; Servius on Aeneid, vi 288), where works have been found containing representations of the Chimaera in the simple form of a lion. In modern art the Chimæra is usually represented as a lion, with a goat’s head in the middle of the back, as in the bronze Chimæra of Arezzo (5th century). The word is now used generally to denote a fantastic idea or fiction of the imagination.

CHIMAY, a town in the extreme south-east of the province of Hainaut, Belgium, dating from the 7th century. Pop. (1904) 3383. It is more commonly spoken of as being in the district entre Sambre et Meuse. Owing to its proximity to the French frontier it has undergone many sieges, the last of which was in 1640, when Turcotte gave orders that it should be reduced to such ruin that it could never stand another. The town is chiefly remembered for the development of its name. Of the numerous strongholds of the Croy family, it has passed through the D’Arenbargs to its present owners, the princes of Craman-Chimay. The castle, which before Turcotte’s order to demolish it possessed seven towers, has now only one in ruins, and a modern chateau was built in the Tudor style in the 18th century. This domain carried with it the right to one of the twelve peerages of Hainaut. Madame Tallien, daughter of Dr Cabarrus, the lady of Thermidor, married as her second husband the prince de Chimay, and held her little court here down to her death in 1835. There is a memorial to her in the church, which also contains a fine monument of Philippe de Croy, chamberlain and comrade in arms of the emperor Charles V. John Froissart the chronicler died and was buried here. There is a statue in his honour on the Grand Place. Chimay is situated on a stream called the White Water, which in its lower course becomes the Viron and joins the Meuse.

CHIME. (1) (Probably derived from a mistaken separation into two words, chimbe bell, of chymbal or chambel, the old form of “cymbal,” Lat. cymbalum), a mechanical arrangement by which a set of bells in a church or other tower, or in a clock, are struck so as to produce a sequence of musical sounds or a tune. For the mechanism of such an arrangement in a clock and in a set of bells, see the articles CLOCK and BELL. The word is also applied to the tune thus played by the bell and also to the harmonious “fall” of verse, and so, figuratively, to any harmonious agreement of thought or action. (2) (From Mid. Eng. chimb, a word meaning “edge,” common in varied forms to Teutonic languages, cf. Ger. Kimme), the bevelled rim formed by the projecting staves at the ends of a cask.

CHIMERE (Lat. chimera, chimæra; O. Fr. chamarre, Mod. Fr. simarre; Ital. simarra; cf. Span. samarra, a sheepskin coat; possibly derived ultimately from Gr. χύμαρος, “wintery,” i.e., a winter coat), in modern English the use of the name of a garment worn as part of ceremonial dress by the Anglican bishops. It is a long sleeveless gown of silk or satin, open down the front, gathered in at the back between the shoulders, and with slits for the arms. It is worn over the rochet (q.v.), and its colour is either black or scarlet (convocation robes). By a late abuse the sleeves of the rochet were, from motives of convenience, sometimes attached to the chimere. The origin of the chimere has been the subject of much debate; but the view that it is a modification of the cope (q.v.) is now discarded, and it is practically proved to be derived from the medieval tabard (tabardum, taberda or collobium), an upper garment worn in civil life by all classes of people both in England and abroad. It has therefore a common origin with certain academic robes (see ROBES, § Academic dress).

The word “chimere,” which first appears in England in the 14th century, was sometimes applied not only to the tabard worn over the rochet, but to the sleeved cassock worn under it. Thus Archbishop Scrope is described as wearing when on his way to execution (1405) a blue chimere with sleeves. But the word did not come into general use till the late 16th century, when the term came to mean a kind of long cloak which was worn as a substitute for the traditional tabard (tabard, tabarder or collobium) as the out-of-doors upper garment of bishops. These chimere, the colours of which (murrey, scarlet, green, &c.) may possibly have denoted academic rank, were part of the civil costume of prelates. Thus in the inventory of Walter Skirlaw, bishop of Durham (1405-1406), eight chimere of various colours are mentioned, including two for riding (pro equitatura). The chimere was, moreover, a cold weather garment. In summer its place was taken by the tippet.

In the Anglican form for the consecration of bishops the newly consecrated prelate, hitherto vested in rochet, is directed to put on “the rest of the episcopal habit,” i.e. the chimere. The robe has thus become in the Church of England symbolical of the episcopal office, and is in effect a liturgical vestment. The rubric containing this direction was added to the Book of Common Prayer in 1662; and there is proof that the development of the chimere into at least a choir vestment was subsequent to the Reformation. Foxe indeed, mentions that Hooper at his consecration wore the chimere as part of his vestments (Acts and Mon. ed. 1563, p. 1511), a source of trouble to himself and of scandal to other extreme reformers; but that this was no more than the full civil dress of a bishop is proved by the fact that Archbishop Parker at his consecration wore surplice and tippet, and only put on the chimere, when the service was over, to go away in. This civil quality of the garment still survives alongside the other; the full dress of an Anglican prelate at civil functions of importance (e.g. in parliament, or at court) is still rochet and chimere.
CHIMSEYAN—CHIMNEYPIECE 165

The continental equivalent of the chimere is the simarra or simarre, which is defined by foreign ecclesiologists (Moroni, Barbier de Montault) as a kind of soute or (cassock), from which it is distinguished by having a small cape and short, open arms (manches-fausses) reaching to only 2 yards above the ground, and enjoying a wide distribution in France and Germany; it is fitted more or less to the figure; in Italy it is wider and falls down straight in front. Like the soute, the simarra is not proper to any particular rank of clergy, but in the case of the latter it is more commonly worn in the citadel of the citadels and bind- ings. It never has a train (casula). It is not universally worn, e.g., in Germany apparently only by prelates. G. Moroni identifies the simarra with the epilogo which Domenico Magri, in his Hierolexicon (ed. 1677), calls the ordinary garment of the clergy general. The soute or cassock (logo) instead of the mantelum (vestis suprema clarae loco pulli), with a cross-reference to Tabardum, the "usual" upper garment (pallium usuale); and this definition is repeated in the 8th edition of the same work. From these it appears that in the first middle of the 16th century the simarra was still in common use as an out-of-doors overcoat. But, according to Moroni, by the latter half of the 19th century the simarra, though still worn by certain civilians (e.g., notaries and students), had become in Italy chiefly the domestic garment of the clergy, notably of superiors, parish priests, rectors, certain regulars, prelates, and cardinals. It was worn also by the Roman senators, and is still worn by university professors. A black simarra lined with white, and so treated that no white is visible under a white collar, is worn by the pope.

More analogous to the Anglican chimere in shape, though not in significance, is the purple mantelum worn over the rochet by bishops, and generally by cardinals. The mantelum is the official vestment of the pope or his legates. This symbolizes the temporary suspension of the episcopal jurisdiction (symbolized by the rochet) so long as the pope or his representative is present. Thus at the Curia cardinals and papal legates in Rome, while in their dioceses they may wear the mantelum, the first act of the cardinal cameralgo after the pope's death is to expose his rochet by laying aside the mantelum, the other cardinals following his example, as a symbol that during the vacancy of the papal See the rochet alone is worn. It is a peculiar garment, which, though the Rev. N. F. Robinson justly points out, is a most unhistorical costume, has no historical justification, and its symbolism is rather unfortunate.

CHIMSEYAN (Y'simsian), a tribe of North American Indians, now some 3000 in number, living on the mouth of the Skeena river, British Columbia, and on the islands near the coast. They are a powerfully built people, who tattoo and wear labrets and rings in noses and ears. They are skilful fishermen, and live in large communal houses. They are divided into clans and distinct social orders.

CHIMKENT, a town of Asiatic Russia, in the province of Syr-darya, 70 m. by rail N.E. of Tashkent. Pop. (1897) 10,756, mostly Sarts. It occupies a strategic position on the west side of the valley between the Alexander range and the Ala-tau (or Talas-tau), at the meeting of commercial routes from (1) Vyrnyi and Siberia beyond, from the north-east, (2) the Aral Sea and Orenburg (connected with it by rail since 1905) to the north-west, and (3) Ferghana and Bokhara to the south. The citadel, which was stormed by the Russians in 1864, stands on high ground above the town, but is now in ruins. Chimkent is visited by consumptive patients who wish to try the koumiss cure. It has cotton mills and soap-works.

CHIMNEY (through the Fr. cheminé, from caminata, sc. camera, a Lat. derivative of caminus, an oven or furnace), in architecture, that portion of a building, rising above the roof, in which are the flues conveying the smoke to the outer air. Originally the term included the fireplace as well as the chimney shaft. At Rochester Castle (1370) and Hedington, Essex, there were no external chimney shafts, and the flue was carried through the wall at some height above the fireplace. In the early examples the chimney shaft was circular, with one flue only, and was terminated with a conical cap, the smoke issuing from openings in the side, which at Sherborne Abbey (A.D. 1300) were treated decoratively. It was not till the 11th century that the smoke issue at the top, and later in the century that more than one flue was carried in one chimney shaft. There are a few examples of the clustered shaft in stone, but a rule for the chimneys to be contemposrates with the general use of brick. The brick chimney shafts, of which there are fine specimens at Hampton Court, were richly decorated with chevrons and other geometrical patterns. One of the best examples is that at Thornton Castle, Gloucestershire.

In the 15th and 16th centuries in France the chimney shaft was recognized as an important architectural feature, and was of considerable elevation in consequence of the great height of the roofs. In the château de Meillant (1503) the chimney shafts are decorated with angle buttresses, niches and canopies, in the late Flamboyant style; and at Chambord and Blois they are carved with pilasters and niches with panelling above, carved with the salamander and other armorial devices. In the Roman palaces they are sometimes masked by the balustrades, and (when shown) take the form of sepulchral urns, as if to disguise the chimney flues. Though not of a very architectural character, the chimneys at Venice present perhaps the greatest variety of terminations, and as a rule the smoke comes out by flues and not through the top.

Factory Chimneys.—Chimneys, besides removing the products of combustion, also serve to provide the fire with the air requisite for burning the fuel. The hot air in the shaft, being lighter than the cold air in the room, rises through them. The chimney is thus used to take its place. An ascending current is thus established in the chimney, its velocity, other things being equal, varying as the square root of the height of the shaft above the grate. The velocity also increases with increase of temperature in the gas column, but since the weight of each cubic foot grows less as the gases expand, the amount of smoke discharged by a chimney does not increase indefinitely with the temperature; a maximum is reached when the difference of temperature between the gases in the shaft and the outside air is about 600° F., but the rate of increase is very slow after the difference has passed about 300° F. In designing a chimney the dimensions (height and sectional area) have to be so proportioned to the size of the fuel and the height of the house that, with it that at the temperature employed the products of combustion are effectively removed, due allowance being made for the frictional retardation of the current against the sides of the flues and shafts and in passing through the fire. The velocity of the current in actual chimneys varies widely, from 30 or 50 or 60 ft. per second. Increased velocity, obtainable by increasing the height of the shaft, gives increased delivering capacity, but a speed of 10 or 12 ft. per second is generally enough, and many factory chimneys do not in general exceed 180 or 200 ft. in height. But very rarely when, as in chemical works, they are employed to get rid of objectionable vapours, they have been made double that height, or even more. In designing them they are treated as octagonal or square. The circular form offers the least resistance, but the problem of design in the height and sectional area requires less material to secure stability than the octagonal and still less than the square; on the other hand, there is more liability of cracking. Brick is the material commonly used, but many chimneys are now made of iron or steel. Reinforced concrete is also employed.

CHIMNEYPIECE, the term given to the projecting hood which in medieval times was built over a fireplace to catch the smoke, and at a later date to the decorative framework, often carried up to the ceiling. "Chimneypiece" or "mantelpiece" is now the general term for the jambs, mantelshelf and external accessories of a fireplace. For many centuries the chimneypiece was the most ornamental and most artistic feature of a room, but as fireplaces have become smaller, and modern methods of heating have been adopted, its artistic as well as its practical significance has grown less.

Up to the 16th century rooms were warmed entirely by a hyper- caust, or with braziers, or by fires on the hearth, the smoke finding its way up to a lantern in the roof. The earliest chimneypiece known is that in the King's House at Southampton, with Norman shafts in the 13th century, and the first chimneypiece in the 14th century that of the great Hall of the manor of Winterborne in the first half of the 14th century. At a later date, in consequence of the greater width of the fireplace, flat or segmental arches were thrown across and constructed with voussoirs, sometimes joggled, the thrust of the arch being resisted by bars of iron at the back. In domestic work of the 14th century the chimneypiece was greatly increased in order to allow of the members of the family sitting on either side of the fire on the hearth, and in these cases great beams of timber were employed to carry the hood; in such cases the fireplace was so...
Chimpanzee—China

Deeply recessed as to become externally an important architectural feature, as at Haddon Hall. The largest chimpanzee existing is in the great hall of the Palais des Comtes at Poitiers, which is nearly 30 ft. wide, having two intermediate supports to carry the hood; the stone slabs forming the roof are also large and weighty. In the early Renaissance style, the chimneypiece of the Palais de Justice at Bruges is a magnificent example; the upper portion, carved in oak, extends the whole width of the room, with statues of nearly life-size of Charles V. and others of the royal family. The earliest examples of gorilla chimneypieces were J. B. Piranesi, who in 1765 published a large series, on which at a later date the Empire style in France was based. In France the finest work of the early Renaissance period is to be found in the chimney-pieces at Villars on the Yonne.

The English chimneypieces of the early 17th century, when the purer Italian style was introduced by Inigo Jones, were extremely simple in design, sometimes consisting only of the ordinary mantel-piece, on which were placed the armorial bearings and shields; the upper chimney breast being panelled like the rest of the room. In the latter part of the century the classic architrave was abandoned in favour of a much bolder and more effective moulding, as in the chimneypieces at Hampton Court, and the skiff was omitted.

In the 18th century the architects returned to the Inigo Jones classic type, but influenced by the French work of Louis XIV. and XV. Figure sculpture, generally represented by graceful figures on each side, which served to carry on the wall, were introduced and the overmantel developed into an elaborate frame for the family portrait over the chimneypiece. Towards the close of the 18th century the designs of the brothers Adam superseded all others, and a century later the French style and fashion. The Adam mantel-pieces are generally decorated with ornament, cast in moulds, sometimes copied from the carved wood decoration of old times.

Chimpanzee (Chimpanzee), the vernacular name of the highest species of the man-like apes, forming the typical representatives of the genus Anthropopithecus. Chimpanzees, of which there appear to be at least two species, range through the tropical forest-zone of Africa from the west coast to Uganda. The typical A. troglodytes has been long known to European science. Dr. Tyson, a celebrated surgeon and anatomist of his time, having dissected a young individual, and described this ape pigeons or H. abd. This is still in use. Of the Fly chimpanzee the skeleton may be seen in the National History branch of the British Museum alongside the volume in which it is described. It was not, however, till 1788 that the chimpanzee received what is now recognized as a scientific name, having been christened in that year Simia troglodytes by the naturalist Johann Friedrich Gmelin. In his classification it was included in the same genus as the orang-utan; and it has recently been suggested that the name Simia pertains of right to the chimpanzee rather than to the orang-utan. Between the typical West African chimpanzee and the gorilla there is no difficulty in drawing a distinction; the difficulty comes in when we have to deal with the aberrant races, or species, of chimpanzee, some of which are so gorilla-like that it is by no means easy to determine to which group they really pertain. In height the adult male chimpanzee of the typical form does not exceed 5 ft., and the colour of the hair is not full black, while the skin, especially that of the face, is light-coloured; the ears are remarkably large and prominent, but the hands reach only a slight distance below the knees. The head is rounded and short, without prominent beetle ridges above the eyes, or a strong crest along the middle line of the back of the skull; and the tusks of the old males are of no very great length and prominence. Moreover, there is no very marked difference in the size of the two sexes. Gentleness and docility are specially characteristic of the species, even when full-grown; while in the native state its habits are thoroughly arboreal.

In central Africa the chimpanzees assume more or less marked gorilla-like traits. The first of these aberrant types is Schweinfurth's chimpanzee (Anthropopithecus schweinfurthi), which inhabits part of Eastern Africa, and is evidently closely related to the same species as the typical race, exhibits certain gorilla-like features. These traits are still more developed in the bald chimpanzee (A. bchezo) of Loango, the Gabun, and other regions of Western Africa, except its English name, which variant is due to the same species as the typical race, exhibits certain gorilla-like features. These traits are still more developed in the bald chimpanzee (A. bchezo) of Loango, the Gabun, and other regions of Western Africa, except its English name, which variant is due to the same species as the typical race, exhibits certain gorilla-like features.
fully half of the kingdom, are, in the north a great alluvial plain and in the south a vast calcareous tableland traversed by hill ranges of moderate elevation (see §§ Mountains and Geology). In north-eastern China there is only one mountain system, the group of hills—highest peak 5060 ft.—forming the Shan-tung peninsula. This peninsula was formerly an island, but has been attached to the mainland by the growth of the alluvial plain. Besides the broad division of the country into western and eastern China it may also be considered as divided into three regions by the basins of its chief rivers, the Hwang-ho (Yellow river) in the north, the Yangtze-kiang in the centre, and the Si-kiang (West river) in the south. In the northern provinces of Kan-suh and Shen-si the basins of the Hwang-ho and Yangtze-kiang are separated by a mountain chain with various names—the eastern termination of the Kuen-lun range of central Asia. These mountains, in China, attain, in the Tsing-ling Shan, a maximum elevation of 13,000 ft. East of Shen-si, in Ho-nan the Fu-mei mountains, or other ranges, but with increasing elevation, and beyond this the delta plain is entered.

The watershed between the Yangtze-kiang and that of the Si-kiang is less clearly marked. It traverses the immense tableland which occupies a great part of the south-west provinces of Yun-nan and Kwei-chow and is continued eastward by the lower tableland of Kang-si and the Nan-shan hills (whose elevation seldom exceeds 6000 ft.). The basin of the Yangtze-kiang forms the whole of central China. Its western border, in Szech-wei and Yun-nan, is wholly mountainous, with heights exceeding 15,000 ft. Central Szech-wei, which is shut in by these mountains on the west; by the Yun-nan and Kwei-chow plateau on the south, by the Ku-lung range on the north, and by highlands eastward (save for the narrow valley through which the Yangtze-kiang forces its way), is a vast red sandstone tableland of about 1600 ft. elevation. It is exceedingly fertile and supports a dense population. Eastward of Szech-wei the Yangtze valley is studded with hills of highest elevations 4000 ft. The basin of the Si-kiang fills the two southern provinces of Kwang-si and Kwang-tung and contains no very striking orographic features. It may be added that in the extreme S.W. portion of China is part of a fourth drainage area. Here the Mekong, Salween, Song-koi (Red river), &c. flow south to Indo-China.

The Coast.—The coast-line, following all the minor indentations, is reckoned at about 4500 m.; but if only the larger inlets and promontories be regarded, the coast-line is about 2150 m. in length. Its shape is that of a semicircle, with its most easterly point midway (30° N.) between its northern and southern extremities. At either end of this coast-line are mountainous headlands between which the sea forms a gulf. In the north, the area of the Shan-tung and the gulf of Chih-li; in the south the Lien-chow peninsula and the gulf of Tongking. Due south of Lien-chow peninsula, separated from the former by a narrow strait, is Hai-nan, the only considerable island of China. From the northern point of the gulf of Chih-li to 30° N., where is Hangchow-bay, the shores are flat and alluvial save where the Shan-tung peninsula juts out. Along this stretch there are few good harbours, except at the mouths of rivers and in the Shan-tung promontory; the sea is shallow and has many shoals. The waters bordering the coast of Chih-li are partly frozen in winter; at 10 m. from the shore the water is only 20 ft. deep. The proximity of Pei-ho and its small ports in the North China plain forms that part of the coast near the mouth of the Pei-ho. In Shan-tung, deeply indented on its southern coast, are the ports of Chi-fu, Wei-haiwei and Tsing-tao (the last in Kiao-chow bay). South of Shan-tung and north of the mouth of the Yangtze-kiang the coast is bordered by a low ridge, the estuaries of which separate between them and the shore. The estuary of the Yangtze is 60 m. across; it contains islands and sandbanks, but there is easy access to Wusung (Shanghai) and other river ports. The bay of Hangchow, as broad at its entrance as the Yangtze estuary, forms the mouth of the Tsin-tang-kiang. The Chusan and other groups of islands lie across the entrance of the bay.

South of Hangchow bay the character of the coast alters. In places, especially with the southern and eastern shores, the coast is generally hilly, often rocky and abrupt; it abounds in small indentations and possesses numerous excellent harbours; in this region are Fu-chow, Amoy, Swatow, Hongkong, Macao, Canton, and other important ports. The coast of Fukien is bordered by small islands. Formosa lies opposite the S.E. coast, the channel between it and Fu-kien province being about 100 m. wide. Formosa protects the neighbouring regions of China from the typhoons experienced farther north and farther south.

Surface.—As already indicated, one of the most noticeable features in the surface of China is the immense deltaic plain in the north-eastern portion of the country, which, curving round the mountainous districts of Shan-tung, extends for about 700 m. in a southerly direction from the neighbourhood of Peking and varies from 150 to 500 m. in breadth. This plain is the delta of the Yangtze-kiang and the Hwang-ho (Yellow river) and forms the Deltaic plain. Beginning in the prefecture of Yung-p'ing Fu, in the province of Chih-li, its outer limit passes in a westerly direction as far as Ch'ang-p'ing Chow, north-west of Peking. Thence running south-westward and eventually joining the Hwang-ho and Yangtze-kiang, and reaching the estuary of the Hwang-ho and Kwang-p'ing Fu till it reaches the upper waters of the Yellow river in Ho-nan. From this point it turns westward and crosses the Hwang-ho or Yellow river in the prefecture of Hwai-king. Leaving Ho-nan, it becomes a wide plain, and, passing west of Ju-ning Fu, in the province of Ho-nan, and more easterly toward as far as Luchow Fu. From this prefecture the course of the river is plain, in which it lies the Chao Lake, stretches southward from Luchow Fu to the Yangtze-kiang, and, traversing the valley of the Yangtze, occupies the region between that river and the Yellow river. To the north of this arm rises a hilly district, in the centre of which stands Nanking. The greater part of this plain descends very gently to the Yangtze-kiang, and, generally below the level of the Yellow river, hence the disastrous inundation which so often accompanies the rise of that river. Owing to the great quantity of soil which is brought down by the waters of the Yellow river, and to the absence of a delta, it is rapidly increasing and the adjoining seas are as rapidly becoming shallower. It was said that the town of Putai was one Chinese mile west of the seashore in the year 200 B.C., and in 1730 it was 15 m. inland, thus giving an encroachment upon the sea of about 100 ft. Again, Sien-shu-kiow on the Pei-ho was on the seashore in A.D. 500, and it is now about 18 m. inland.

Some of the ranges connected with the mountain system of central Asia which enter the western provinces of China have been mentioned above, others, called the mountains of the eastern portion of Tibet the Kuen-lun range throws off a number of branches, which spread first of all in a south-easterly direction and eventually take a north and south course, partly in the provinces of Sinkiang and Yunnan, and divide the beds of the rivers which flow into Siam and French Indo-China, as well as the principal northern tributaries of the Yangtze-kiang. In the north-west, traversing the western portion of the province of Szech-wei, the range of the Kuen-lun forms a prolongation of the northern Tibetan mountains. They are known as the Lung-shan, Richtshofen and Nan-shan, and join on the south side the Kuen-lun range. The Richtshofen range (locally called Tien-shan) is a mountainous range of about 2000 ft. Several of its peaks are snow clad, and there are many glaciers. Forming the northern frontier of the province of Szech-chen run the Min-shan and the Kiu-long (or Po-mêng) ranges, which, entering China in a W.E. extend in a general easterly course as far as 112° E. in the province of Hu-peh. These ranges have an average elevation of 8000 and 11,000 ft. respectively. In the south a number of parallel ranges spread from the Yun-nan plateau in an easterly direction as far as 90° E.; the range of the Hsi-shan, which extend they run in lines often parallel with the coast, and cover large areas of the provinces of Fu-kien, Kiang-si, Cheh-kiang, Hu-nan and southern Kiang-nan, until they reach the Yangtze-kiang; the valley of the Hsi-shan is one of the chief waterways in the forming their northern boundary. In Fu-kien these hills attain the character of a true mountain range with heights of from 6500 to nearly 10,000 ft. Besides the chief ranges there are the Tai-hang Mountains in Shan-si, and many others which may be mentioned the range, a part of the escarpment of the Mongolian plateau—which form the northern frontier of Chih-li. Here the highest peak is Ta-kuang-tsing-tzu (6500 ft.), about 300 m. N.E. of Peking and immediately near the mouth of Wei Ch'ang (the imperial hunting grounds).

Rivers and Canals.—The rivers of China are very numerous and there are many canals. In the north the rivers are only navigable by small craft; elsewhere they form some of the most frequent waterways in the country. Among the most important are the Yangtze-kiang and the Hwang-ho (Yellow river), which are separately noticed. The Hwang-ho (length about 2400 m.) has only one important tributary in China, the Wei-ho, which rises in Kan-suh and flows through a very mountainous country. It has been in about 39° N., or in the neighbourhood of the present mouth of the Pei-ho, and the most southerly being that which existed before the change in 1851–1853, in 34° N. Owing to its small value as a navigable waterway and to its small importance in its neighbourhood, there are no considerable towns on its lower course. The Yangtze-kiang is the chief waterway of China. The river, flowing through the centre of the country, after a course of 2900 m., empties itself into the Yellow Sea in about 31° N. Unlike the Yellow river, the Yangtze-kiang is dotted along its navigable portions with many rich and populous cities, among which are Nanking, An-ch'ing (Nanking), Kiu-kiang, Hankow and Ich'ang.

1 A Chinese mile, H, or le = o-36 English mile.
From its mouth to I-ch'ang, about 1000 m., the river is navigable by large steamers. Above this last-named city the navigation becomes impossible for any but light native craft or foreign vessels specially constructed for the navigation, by reason of the rapids and the series of falls. The river occupies a mountain gorges through which the river runs between Kwei-chow and I-ch'ang. Above Kwei-chow it receives from the many north tributaries, notably the Min, which water the low table-land of central Szechwan. The river, however, is navigable for small steamers—"barges," as the Chinese call them—up to Fung-chow, a distance of about 850 m., and still navigable, although not without great trouble, as far as the entrance to the great She-kiang, or Yangtze, at Peking.

The Yangtze-kiang. The Yangtze-kiang is the chief and most important channel of the Yangtze basin, and plays a part of immense importance in the political and military history of China.

The course of the river. The river flows from its source in the Po-meng, or 'White Mountain,' to the north of the city of Kwei-chow or Chien-foo to the south, and here it is navigable for small steamers—the classification of this word being, however, very uncertain—up to 200 m., and to large steamers for about 2000 m. northwards from the mouths of the South-nan-kiang, or Min, to the town of Ho-nan, where it appears to have a certain difficulty in descending, but still navigable for steamers of large size. It then passes into the south-nan-kiang, or Min, which is navigable by small steamers as far as the town of Peiho, about 1000 m. from the mouth, and here it is as wide as 1500 ft.

The course of the river is divided into three parts: the upper, or mountainous, which extends from its source to the city of Chien-foo; the middle, or navigable, which extends from Chien-foo to the town of Peiho; and the lower, or alluvial, which extends from Peiho to the mouth. The upper part of the river is characterized by its rapidity and the number of its branches, which are formed by the junction of the various streams that flow into it from the mountains of the north. The middle part is characterized by its great width and the number of its affluents, which are formed by the junction of the various streams that flow into it from the fertile plains of the Yangtze basin. The lower part is characterized by its calmness and the number of its affluents, which are formed by the junction of the various streams that flow into it from the alluvial plains of the Yangtze basin.

The course of the river is divided into three parts: the upper, or mountainous, which extends from its source to the city of Chien-foo; the middle, or navigable, which extends from Chien-foo to the town of Peiho; and the lower, or alluvial, which extends from Peiho to the mouth. The lower part is characterized by its calmness and the number of its affluents, which are formed by the junction of the various streams that flow into it from the alluvial plains of the Yangtze basin.
Great Deep Lake. In ancient times it went by the name of the Ku-kiang Hu, or Lake of the Nine Rivers, from the fact that nine rivers flowed into it. Its chief affluents are the Siang-kiang, which rises in the highlands in the north of Kwang-si and flows in a general N.W. direction to the Yangtze-kiang at Yenchin; the Sung-ch'uan, which is the largest of the tributaries, rises near the eastern border of Kwei-chow. The lake is connected with the Yangtsze-kiang by two canals, the Taping and the Yochow Fu. In summer it is fed by the overflow from the Yangtsze-kiang; in winter it drains into both of the Yochow Fu canals.

During the winter and spring the water of the lake is so low that the shallow portions become islands, separated by rivers such as the Siang and Yuen, and numberless streams; but in summer, owing to the rise in the waters of the Yangtsze-kiang, the whole basin of the lake is filled. It is then about 75 ft. deep, and its greatest width is about 180 m. E. of the Tung-ting lake is the Poyang lake, which occupies the low-lying part of the province of Kiang-si, and is connected with the Yangtsze-kiang by the Hucow canal. The Poyang lake is also fed by the overflow from the Yangtsze-kiang, and its surface is not quite to the same extent as the Tung-ting lake, and its landmarks are more distinctly defined. It is about 90 m. long by 20 broad. The Ts'ai lake, in the neighbourhood of Su-chow, is also a lake of this type, but it is not so large and lies in the south of the province of Cheh-kiang and Kiang-su crosses its blue waters, and its shores are divided among thirteen prefectures. Besides these lakes there are, among others, two in Yun-nan, the Kun-yang-hai (which was built by the emperor Ti-yuang in 164 a.) and the Sung-chow Fu, which in 40 m. long and is connected with the Yangtsze-kiang by the Pu-to river, and the Ehr-hai (Urh- hai) to the east of the city of Tali.

The Great Wall.—Along the northern provinces of Chih-li, Shan-si, Shen-si, and Chih-lia that portion of the Great Wall of China, built to defend the country against foreign aggression. It was begun in the 3rd century B.C., was repaired in the 15th, and in the 16th century was extended by 300 miles. Following the coast it is, at Shan-hai-kwan on the gulf of Liao-tung, where the Chinese and Manchurian frontiers meet, it goes eastward past Peking (which is about 35 m. to the south) and then trends S. and E. across Shan-si to the Huang-ho. From the northwestern part of the Flattest to the east, a line from Shan-hai-kwan to Peking, or the wall (northern) wall passes through Kalnus, thus guarding the pass into Mongolia. A branch wall serves the greater part of the western frontier of Chih-li from Shan-si. West of the Huang-ho the wall (southern) wall is the northern frontier of Shan-si, passing through the central Asia to China through Kan-suh and Shan-si by the valley of the Wei-ho, tributary of the Huang-ho. Between these two branches of the wall there is a branch wall running west and south to protect the Tibetan frontier. The wall, which is about 30 m. wide and 6 ft. thick at the base, of some 200 m. is wide, is 12 ft. wide. The wall is carried over valleys and mountains, and in places is over 4000 ft. above sea-level. The passes through the wall or the wall are: the passes through the Great Wall (Shan-hai), the Kalgan pass, the Yenmun passes (at the N. of Shan-si) and the K'ai-yu pass in the extreme west, through which runs the caravan route to Barkal in Turkestian. Colonel Dewar, who was the last to visit the Great Wall at over twenty places widely apart and gathered many descriptions of it in other places, states that its present state is poorly known on the maps of the time (1897) in a number of places and other places are surrounded by houses and places where it forms a substantial boundary in the valley bottoms, on the passes and where it crosses main routes. These marks apply with particular force to the branch running southwest from the Nan-k'ang passes through the southern frontier of Shan-si, and west of it, where the wall is originally built by degrees and in sections, not of hewn stone, but of round boulders and earth, the different sections being repaired as they fell into ruin. Only in the valley bottom about 90 miles from Peking, and the northern part of the wall for 25 miles, has the wall been built of solid masonry all those sections through which a likely road for invading Tartars to follow, or where it could be seen at a distance in the sky-line. The building of the wall was a "wonderful achievement. Not to be surpassed in time, and not in building the pyramids of Egypt."

Climate.—The climate over so vast an area as China necessarily varies greatly. The southern parts of Yun-nan, Kwang-si and Kwang-tung (including the city of Canton) lie within the tropics. The northern zone (in which lies Peking) by contrast has a climate of long, cold winters and hot summers. In the centre of China, the influence of the great plateau of Mongolia tends to establish uniform conditions unusual in so large an area. The prevailing winds during summer are southerly, and in winter northerly; they are warm and moist in summer, and cold and dry. From October to May the climate of central China is bracing and enjoyable. The rainfall is moderate and regular. In northern China the inequalities both of temperature and rainfall are very great. The temperature of the Great Wall of China is so low that the heat is as intense as is the cold of winter. In summer the rains often render the plain swampy, while the dry persistent westerly winds of spring create dust storms (experienced by Peking from March to June). The rainfall is, however, uncertain, and thus the harvests are precarious. The provinces of Shan-tung and Shan-si are peculiarly liable to prolonged periods of drought, and consequent severe famines such as that of 1877-1878, when many millions of people died, and there was a considerable exodus of people. The summer months, July to September, are very hot, when snow usually falls in December and January.

At Canton on the south coast the hot season corresponds with the rains. Canton was visited in October to (end of April) and the N.E. monsoon. Further north, at Shanghai, the S.W. monsoon is sufficiently felt to make the prevailing wind in summer southerly.

The Chinese Empire is divided into the following provinces: Cheh-kiang, Chih-li, Fu-kien, Nang-hui (An-hui), Ho-nan, Hu-nan, Hu-pei, Kan-suh, Kiang-si, Kiang-su, Kwang-si, Kwang-tung, Kwei-chow, Shan-si, Shan-tung, Shen-si, Szech-chen and Yun-nan. See the separate notices of the provinces and the article on Shanghai, the southern province of Manchuria. Geology.

The Palaeozoic formations of China, excepting only the upper part of the Carboniferous system, are marine, while the Mesozoic and Tertiary deposits are estuarine and freshwater or else of terrestrial origin. From the close of the Palaeozoic period down to the present day the greater part of the empire has been dry land, and it is only within the last 200 years that it has become a great marine region. Although there is no evidence of a Mesozoic sea has yet been found. The geological sequence may be summarized as follows:

Archean. Geiuii, crystalline schists, phylites, crystalline lime schists, quartzite, etc.

The Siunlin.—Sandstones, quartzites, limestones. Sometimes rests upon the Archean; in some cases the Archean is generally thin; but sometimes, according to Lézéy, there is no unconformity. Covers a large area in the northern part of China proper; absent in the eastern Kuen-lun; occurs again in the ranges of S.E. China. In some cases there is a repetition of the Archean series; they belong to the oldest known fauna upon the earth, the fauna of the Olenelus zone. It is, however, not improbable that in many places beds of considerably later date have been included in the Siunlin system.

1 The portion of the wall which abutted on to the sea has been destroyed.

2 See the Geog. Jnl. (Feb. and March 1907). For a popular account of the wall, with numerous photographs, see The Great Wall of China (London, 1909), by W. E. Giel, who in 1908 followed its course from east to west. Also A. Willoughby's Journey in North China (London, 1870); and Martin, "La Grande Muraille de la Chine," Revue scientifique (1891).
Ordovician.—Ordovician fossils have been found in the Lung-shan, Kiang-su (about 50 m. east of Nan-king), in the south-west of Cheh-kiang and in the south-east of Yunn-nan. Ordovician beds probably occur also in the Kuen-lun. These and similar slates with Silurian and other Ordovician fossils have been found in Sze-ch’u-en.

Devonian.—Found in Kan-suh and in the Tsing-ling-shan, but becomes much more important in southern China. Occurs also on the south of the Tsin-shan, in the Al cyn- tagh, the Nan-shan and the west of Siam.

Carboniferous.—Covers a large area in northern China, in the plateau of Shen-sha and Shan-si, extending westwards in tongues between the folds of the Kuen-lun. In this region it consists of a lower and an upper formation. The lower formation consists of plant beds and sandstones with seams of coal, which may perhaps be in part of Permian age. This is the most extensive coalfield in the world.

In southern China the whole series consists chiefly of limestones, and the older rocks are commonly denuded. The Mesozoic beds are also found in the Tsin-shan, the Nan-shan, Kan-suh, on the southern borders of the Gobi, &c.

Mesozoic.—Marine Triassic beds containing fossils similar to those of the German Muschelkalk have been found by Loczy near Peking, on the eastern border of the Tibetan plateau. Elsewhere, however, the Mesozoic is represented chiefly by a red sandstone, which covers the greater part of Sze-ch’u-en and fills also a number of troughs among the older rocks of southern China. No marine fossils are found in this sandstone, but remains of plants are numerous, and these belong to the Rhacian, Lias and Lower Oolite. No Cretaceous beds are known in China excepting in S. Tibet (on the shores of the Tengi-nor) and in the western portion of the Tianschan.

Cainozoic and Recent.—No marine deposits of this age are known. Although the loess of the great plain and the sand of the desert are still in process of formation, the accumulation of these deposits proceeds very slowly.

Volcanic Rocks.—Amongst the Archean rocks grannitic and other intrusions are abundant, but of more modern volcanic activity the remains are comparatively scanty. In southern China there is no evidence of pre-Palaeozoic volcanic activity. In the Archean mountain regions fossils occur in the great plain of north China. In the Liao-tung and Shan-tung peninsulas there are basaltic plateaux, and similar outpourings occur upon the borders of Mongolia. All these outpourings are secondary to the granite intrusions.

Loess.—One of the most characteristic deposits of China is the loess, which is not merely impervious to water China the physical character of the loess, but also determines the agricultural products, the types of crops which are economically valuable to the people of the country. It is peculiar to north China and it is not found south of the Yangtze. The loess is a solid and friable earth of brownish-yellow colour, and when triturated with water is not unlike loam, but differs from the latter in being highly porous and tubular structure. The loess is well and extremely favourable to agriculture. (See Loess and infra, § Agriculture.)

The loess is called by the Chinese Huang-fu, or yellow earth, and it has been suggested that the imperial title Huang Ti, Yellow Emperor, is the result of a phonetic error. There is no doubt in the fact that the emperor is lord of the loess or yellow earth.

Structurally, China proper may be divided into two regions, separated from each other by the folded range of the Tsing-ling-shan. These regions are the northern and the southern. The former extends from W. 30°E. to E. 30°N., while the latter lies south of 30°N. The northern China is a plateau, level generally, with only several ranges of mountains. The southern China is a large depression with several ranges of mountains. The structure of the southern China is more complex than that of the northern China. It has a great number of ranges of mountains, some of which are quite sharp, while others are more gentle. The northern China is a more level and extensive plain, while the southern China is more mountainous.

The present configuration of China is due, in a very considerable degree, to faulting. The abrupt eastern edge of the Shan-shan plateau, where the western and eastern plateaux of fault, or rather a series of step faults, with the downthrow on the east. Richthofen has shown reason to believe that this line of faulting is continued far to the south and to the north. He believed also that the present coast-line of China has to a large extent been determined by the movement along these faults.

Concerning the structure of the central Asian plateau our knowledge is still incomplete. The great mountain chains, the Kuen-lun, the Nan-shan and the Tsin-shan, are belts of folding; but the Miocene deposits in the western part of the plateau consist chiefly of the Miocene deposits, which have been formed by a series of faults, with a downthrow on the north. The Miocene deposits are also present in the central part of the plateau, where they are interbedded with the Miocene deposits of the north.

China lies within two zoological provinces or regions, its southern portion forming a part of the Oriental or Indian region and having a fauna similar to that of the Indian fauna; the northern part belongs to the European region, though the fauna of the latter is more closely related to that of the former. The giant salamander of the rivers of China and Japan and the Chinese mandarin duck are by some included in the same genera as their American representatives, while others they are separated as distinct species. Whichever view we take does not alter the close relationship. One wapiti occurs on the Tibetan frontier, and others in Manchuria and Amurland.

As regards mammals and birds, the largest number of generic and specific types peculiar to China are met with in Sze-ch’u-en. Foremost among these is the great panda (Ailurus fulgens), representing a genus by itself, probably related to bears and to the true panda (Ailurus), the latter of which has a local race in Sze-ch’u-en. Next in the list of generic types is the giant cat, the snow leopard (Panthera uncia), a typical type which is native to Sze-ch’u-en, while a second is found on the upper Mekong, and a third in the mountains of central China. In the Indomalaya the swimming-shrew (Nectogege) forms another generic type peculiar to China. One of the typical types is the giant musk-rat, Sclater (Scapichirus, Urops, in, native to the Japanese Urotschus, of Scaptonyx, which connects the latter with the moles (Talpa), and of Neotragus, a relative of the Malay rat-shrews (Gymnura). Here also two types are found, one of which is characteristic of India, the other of China and Japan. The Himalayan black and the Malay bear have each a local race in Sze-ch’u-en, where the long-haired Fontanier’s cat (Felis tristis) and the Tibet cat (F. scripta) connect the latter with the rare cat (F. lemmehicki), a Malay type, is represented by local forms in Sze-ch’u-en and Fu-chow. The Amurleopard and Manchurian tiger are characteristic types of their respective species.

Birds.—Among the more prominent there are the pheasants and the partridges, which belong to the genus (Budorcas) form the Pater, while the Mischmi (Phasianus) and the Shih (Macacus) are among the most common to China and Japan. The Himalayan and the Burmese-Malay types, on the other hand, are represented by a race of the Kashmir hangul deer. Of other deer, the oriental musk deer (Moschus moschiferus, whose habitat is the Peking region, is unknown. The sika group, which is peculiar to China, Japan and Formosa, is represented by Cervus hermit in Manchuria and the smaller C. manchuricus and sikha in that province and in the island of Formosa, while the larger C. nipponicus, which is found in Kan-suh, is common to China and Japan. The small deer (Hylobates) and the large bamboo-rat (Hylobates) are also characteristic of the country.

In detail to the numerous forms of rodents inhabiting China, it is impossible here, and it must suffice to mention that the flying-squirrels (Pteromys) are represented by a large and handsome species which is found in the territory of the Altai, and forms the largest kind of bamboo-rat (Rhimostomus), the other species of which are found in central and western China. The small deer (Hylobates) and the large bamboo-rat (Hylobates) are also characteristic of the country.

To give an adequate account of Chinese ornithology would require space many times the length of this article. The great mandarin duck (Aix galericulata) is found in India and north-western China, whence the group ranges into the eastern Himalaya. Among Chinese species are the golden pheasant (Chrysolophus pictus), the greater golden pheasant (Cinclus) and the lesser golden pheasant (Cinclus), three out of the five species of Sino-orientalis, the other two being Tibetan, two kinds of Phasianus, the golden pheasant alone among the Lesser golden pheasant, and Fringillidae and Turdus, a few of several species of the typical genus Phasianus, among which it will suffice to mention the
long-tailed *P. reesi*. The Himalayan bamboo-partridges (*Bambusicola*) have also a Chinese representative. The other long-tailed crane that can be mentioned is the Manchurian crane, misnamed *Grus japonensis*. Pigeons include the peculiar subgenus *Dendroplegus*; while partridges, *Alectoris*, and the White Hind (Hibiscus), another Eastern Halartic type, constitute the common element in the avifauna. Little would be gained by naming the genera, peculiar or otherwise.

China has a few peculiar types of freshwater tortoises, among which *Ocadia sinensis* represents a genus unknown elsewhere, while there is also a species of the otherwise Indian genus *Dermochelys*. The Chinese alligator, *Dermochelys sinensis*, has been already mentioned. Among lizards, the genera _Plestiodon_ and _Cristina_ of China, which the two latter are very characteristic of the Oriental region, range through China to Japan; and among snakes, the Malay salamander (*Cryptobranchus* or *Megalobatrachus*), a species, as mentioned above, a type found elsewhere only in North America, while _Hynobius_ and _Osychodactylus_ are peculiar generic types of salamanders. Among fishes, it must suffice to refer to the spoon-beaked sturgeon (*Psephurus*) of the Yangtsze-Kiang, and the numerous minnows some extraordinary species of carp and the so-called nile carp of China in which these native carp the Chinese have produced two highly coloured breeds, the goldfish and the telescope-eyed carp.

Among the invertebrates special mention may be made of the great atherines silk-moth (*Attacus*), common in northern China and Japan, and also of its Manchurian relative _A. pernyi_; while it may be added that the domesticated "silkworm" (*Bombyx mori*) is generally believed to be of Chinese origin, although this is not certain. Very characteristic is the fact that, of all the invertebrates except the swallow-tailed butterflies of the family *Papilionidae*, the Chinese kercms (*Coccus sinensis*), is also worth mention, on account of its yielding wax. As regards land and freshwater snails, China exhibits a fauna that is rather limited and included, with the exception of the great French snail, the Chinese province displays decided peculiarities of its own being *Helix* (in the wider sense) and _Claudilia_. There are, for instance, nearly half a score of subgenera of *Helix* whose headquarters are Chinese, while the true snails are represented by similar or identical species. The western provinces species of *Bulimus* are abundant, and in the operculate group *Hedea* forms a peculiar type akin to *Helicina*, but with internal foldings to the shell.

It has been noticed that the waters of the Yangtsze-Kiang are inhabited by a small jelly-fish, or medusa (*Linnocodium kwaiti*), near akin to _L. souverii_ which was discovered in the hot-house tanks in the Botanical Gardens in the Regent's Park, London, but whose real home is probably the Amazon.

( _R. L._)

**Flora.**

The vegetation of China is extremely rich, no fewer than 9000 species of flowering plants having been enumerated, of which nearly 5970 are not known to occur elsewhere. Whole provinces are as yet only partially explored; and the total flora is estimated to comprise ultimately 12,000 species. China is the continuation eastward of the great Himalayan mountains, and is inhabited by the same species of forest trees and shrubs. Thousands of deep narrow valleys form isolated areas, where peculiar species have been evolved. Though the greater part of the country has long ago been cleared of its primeval forest and submitted to agriculture, there still remain some extensive forests on the rims of China in which the original flora is well preserved. Towards the north the vegetation is palaearctic, and differs little in its composition from that of Germany, Russia and Siberia. The flora of the western and central provinces is comparable to that of East Asia, from which it reaches down to the sea-board. While towards the south this element mingles with species derived from Indo-China, Burma and the plain of Hindostan. Above a certain elevation, decreasing with the latitude, but approximately 6000 ft. in the middle of China, there is a spruce forest in the great rivers, extensive forests of conifers, like those of Central Europe in character, but with different species of silver fir, larch, spruce and Cembran pine. Below this altitude the woods are composed of deciduous and evergreen broad-leaved trees and shrubs mingled together in a profusion of species. Pure broad-leaved forests of one or two species are rare, though small woods of oak, of alder and of birch are occasionally seen. There is nothing comparable to the redwood of the Pacific Coast of North America, which has been abundant high in the rain forest as well as on the mountain slopes. Pine forests occur at low levels, but are always small in extent.

The appearance of the vegetation is very different from that of the United States, which is comparable to China in situation and in extent. Though there are 60 species of oak in China, many with magnificent foliage and remarkable cupules, the red oaks, so characteristic of North America, with their bristle-pointed leaves, turning beautiful colours in autumn, are quite unknown. The great coniferous forest of the Rocky Mountains has no analogue in China, the gigantic and preponderant Douglas fir being absent, while the giant *Sequoia* are represented only on a small scale by *Cryptomeria*, which attains half the height of the American species.

Certain remnants of the Miocene flora which have disappeared from Europe are still conspicuous and similar in North America. In both regions there are several species of *Magnolia*; one in the United States, *M. liliiflora*, and another in the vicinity of the Gulf of Mexico, *M. shorteri*. The peculiar family of the *Gymnospermae* is represented by the genera *Gnetum* and *Gnethusia*; and by the curious species of the genus *Cycas*. The *Carya* is another genus of pecan, which occurs both in South America and China.

There are numerous genera of palms, some of which are indigenous to China, and others, as *Elaeis guineensis*, or *E. dives,* are known only from the Chinese gardening.
China

Social Life

The awakening of the East which has followed the Russo-Japanese War of 1904-5 has affected China also. It is too soon to say how far the influx of European ideas will be able to modify the immemorial customs and traditions of perhaps the most conservative people in the world; but the process has begun, and this fact makes it difficult to give a picture of Chinese habits and customs which shall be more than historical or provisional. Moreover, the difficulty of presenting a picture which shall be true of China as a whole is enhanced by the different characteristics observable in various regions of so vast a country. The Chinese themselves, until the material superiority of Western civilization forced them to a certain degree to conform to its standards, looked down from the height of their superior culture with contempt on the "Western barbarians." Nor was their attitude wholly without justification. Their civilization was already old at a time when Britain and Germany were peopled by half-naked barbarians, and the philosophical and ethical principles on which it was based remained, to all appearances, as firmly rooted as ever. That these principles have, on the whole, helped to create a national type of a very high order few Europeans who know the Chinese well will deny. The Chinese are naturally reserved, earnest and good-natured; for the occasional outbreaks of ferocious violence, notably against foreign settlements, are no index to the national character. There is a national proverb that "the men of the Four Seas are all brothers," and even strangers can travel through the country without meeting with rudeness, much less outrage. If the Chinese character is inferior to the European, this inferiority lies in the fact that the Chinaman's whole philosophy of life inclines him to change or to energetic action. He is industrious; but his industry is normally along the lines marked out by authority and tradition. He is brave; but his courage does not naturally seek an outlet in war. The jealously exclusive empire, into which in the 19th century the nations of the West forced an entrance, was organized for peace; the arts of war had been all but forgotten, and soldiers were of all classes the most despised.

The whole social and political organization of the Chinese is based, in a far more real sense than in the West, on the family. The supreme duty is that of the child to its parent; on this the whole Chinese moral system is built up. Filial piety, according to the teaching of Confucius, is the very foundation of society; the nation itself is but one great family, and the authority of the government itself is but an extension of the paternal authority, to which all its children are bound to yield implicit obedience. The western idea of the liberty and equality of the individual is alien to the Chinese, everything to which he belongs, is wholly alien to the Chinese mind. The political unit in China is not the individual but the family, and the father of the family is supposed to be responsible for the qualities and views of all his children. He is rewarded for their virtues, punished for their faults, and is the father and master of all his ancestors, and conversely his crimes disgrace them.

An outcome of this principle is the extraordinary importance in China of funeral rites, especially in the case of the father. The eldest son, now head of the family, or, failing him, his first-born or adopted son, fixes one of the three souls of the dead in the tablet commemorating his virtues, burns incense to his shade, and supplies him with paper money and paper representations of everything (clothes, servants, horses) that he may require in his journey to the next world. Mourning lasts for three years, during which the mourners wear white garments and abstain from meat, wine and public gatherings. Custom, too, dictates that wherever the Chinaman may live he should bring with him either a square or a circular burial mound. One of the objects of the friendly societies is to provide funds to charter ships to transport home the bodies of those who have died abroad. Annually, in May, the white-clad people stream to the graves and mournful ritual is performed. The only feeling that ever arises is a hatred of the death. Christian missionaries have found in this ancestor worship the most serious obstacle to the spread of a religion which teaches that the convert must, if need be, despise his father and his mother and slay his Christ.

The same elaborate ceremonial that characterizes the Chinese funeral customs is found also in their marriage rites and the rules of their social intercourse generally. Confucius is reported to have said that "the virtues (of the family) are inculcated in the home." The observance of the "ceremonial" (6) in the fulfilling of social duties is that which, in Chinese opinion, distinguishes civilized from barbarous peoples. The Board of Rites, one of the departments of the government, is in charge of regulations regarding marriage in matters of etiquette and ceremony. As to marriage, the rule that the individual counts for nothing obtains here in its fullest significance. The breeding of sons to carry on the ancestral cult is a matter of prime importance, and the marriage of a young man is arranged at the earliest possible age. The bride and bridegroom have little voice in the choice of their partners, marriage being arranged for them by their parents, and the ceremony of marriage is a formal, solemn one.
in the matter, the match being arranged by the parents of the parties; the lifting of the bride’s veil, so that the bridegroom may see her face, is the very last act of the long and complicated ceremony.

Traditional Chinese social system four classes are distinguished: the literatry, the agricultural, the artisan and the trading class. Hereditary nobility, in the European sense, scarcely exists, and the possession of an hereditary title gives in itself no special privileges. Official position is more highly esteemed than literatry and about four or five hundred years ago the Emperor himself, and thence his relatives, gave up official life and went to live in the wilds of the west. There are, nevertheless, besides personal decorations for merit, such as the yellow jacket, five hereditary rewards for merit; these last only for a fixed number of lives. A few Chinese families, however, have the right of granting, to their members, the title of Imperial consort, which is being the Holy Duke of Yen (the descendant of Confucius). The Imperial Clansmen consist of those who trace their descent direct from the founder of the Manchu dynasty, and are distinguished by having a red patch on the rear of their official clothes, which is the distinguishing mark of the imperial house a red girdle. Twelve degrees of nobility (in a descending scale as one generation succeeds another) are conferred on the descendants of every emperor; in the thirteenth generation the descendants of emperors are merged in the imperial population, save that they retain the yellow girdle. The heads of eight houses, the “Iron-capped” (or helmeted) princes, maintain their titles in perpetuity by rule of primogeniture in virtue of having held the rank of Duke in the conquest of China. Imperial princes apart, the highest class is that forming the civil service. (See also Government and Administration.) The peasantry class forms the bulk of the population. The majority of Chinese are small landowners; their standard of living is very low in comparison with European standards. Their occupation is what is called self-supporting. Even if he wished to do so, he could leave his land to one son. There must be substantially an equal division, the will of the father notwithstanding. As early marriages and large families are the rule, this problem of inheritance can be easily understood. The average family consists of about eight persons and there are many small families. The average number of persons, of which about one-third is due to the irreducible minimum in many places. Small patches of one-tenth or even one-twentieth of an acre are to be found as the estate of an individual landowner, and the vast majority of holdings run between one and three acres. With three acres a family is deemed very comfortable, and the possession of ten acres means luxury.

The only class which at all resembles the territorial magnates of other countries is the clan of which the chief is the official who is not infrequently invested in land, and consequently there are in most provinces several families with a country seat and the usual insignia of local rank and influence. On the decease of the head or founders of such families it is considered dignified for relatives to sit to live together, sharing the rents and profits in common. This is sometimes continued for several generations, until the country seat becomes an agglomeration of households and the family a sort of clan. A family of this kind, whatever its rank, consists of sons, husbands, and young men, is constantly sending its scions into the public service. These in turn bring their earnings to swell the common funds, while the rank and dignity which they may earn add to the importance and standing of the group as a whole. The members of this class are usually termed the literati or gentry.

The complex character of the Chinese is shown in various ways. Side by side with the reverence of ancestors the law recognizes the right of sons to founders of such families is it considered dignified for rich poor this is not an uncommon practice, though in comparison with the total population the number of slaves is few. The kidnapping of children for sale as slaves is carried on, but there is no slave building. This is a characteristic of the Javanese. The women of the upper classes are treated with much respect. The home of a Chinese man is often in reality ruled by his mother, or by his wife as she approaches old age, a state held in veneration. Chinese women frequently prove of excellent business capacity, and those of high rank in the more recent periods of Chinese history have uncommonly enjoyed exercise considerable influence on public affairs.

Deforming the feet of girls by binding and stopping the growth has been common for centuries. The toting walk of the Chinese lady resides in the deformation of the feet is the admiration of her husband and friends. Foot-binding is practised by rich and poor in all parts of the country, but is not universal. In southern and western China Hakka women and certain others never have their feet bound. It has been claimed that more than one-third the total population of China take for secondary wives natural-footed women, who are frequently

---

1 Evidences of the social changes taking place in China are to be found in the strong movement for the education of girls, and in the formation of societies, under official patronage, to prevent the binding of women’s feet.

2 It must be remembered that there is great variety in the costuming of women of different provinces. The particulars here given are of the most general styles of dress.
native wines are made. The Chinese are, however, abstemious with regard to alcoholic liquors. Water is drunk hot by the very poor, as a substitute for tea. Tea is drunk before and after meals in cups without handle or saucer; the cups are always provided with a cover. The main meals are taken during the day—in the morning, at noon, and at night; the last named at varying hours from four till seven o’clock. At dinner a rich man will offer his guest twenty-four or more dishes (always a multiple of 4), four to six dishes being served at a time. Food is customarily served cold, and Chinese meals (especially those in the garish and lively entrepot-lands) are apt to disgust the Western stomach at first—such things as raw fish, and fish with pickled green and red porcellain spoons. Men dine by themselves when any guests are present; dinner parties are sometimes given by ladies to ladies. Chinese cookery is excellent; in the culinary art the Chinese are remarkable, even second to the Tartars.

Ethnologically the Chinese are classed among the Mongolian races (in which division the Manchus are also included), although they present many marked contrasts to the Mongols. The Tartars, Tibetans, Burmese, Shan, Manchu and other races—including the Ainus—were by certain eminent ethnologists considered as genuine and unmixed semi-Mongolized Chinese, while other authorities held that it was indigenous in eastern China. Notwithstanding the marked differences between the inhabitants of different provinces and even between those living in the same province, certain features are common to all the races. The body is generally of moderate height; men do not exceed 5 ft. 4 in., except in the North. The head is normally brachycephalic or round horizontally, and the forehead low and narrow. The face is round, the mouth large, and the chin small and rounded. The eyes are pricks with prominent promontorium, oblique upwards and outwards, and the hair coarse, lank and invariably black. The beard appears late in life, and remains generally scanty. The eyebrows are straight and the iris of the eye black. The nose is prominent, often short and flat. The arms and legs are of moderate length, and the feet are disproportionately small, and the body early inclines to obesity. The complexion varies from an almost pale-yellow to a dark-brown, without any red or ruddy tinge. Yellow, however, predominates.

A few words may be added concerning the Manchus, who are the ruling race in China. Their tribal affinities are not precisely known, but they may be classed among the Ural-Altaic tribes, although the term Ural-Altaic (q.v.) denotes a linguistic rather than a racial group. By some authorities they are called Manchus. The Tartars, i.e. Eastern Tartars, i.e. Eastern Tatars, of the Tatars of to-day being of true Mongol descent. Manchus is the name adopted by certain tribes which led a nomadic life in Manchuria and were known collectively in the 11th and 12th centuries as Manchus. Some of the Tartars (whence the European form Cathay), who in the 9th and 10th centuries dwelt in the upper Liao region, as the ancestors of this race. It was not until the 16th century that the people became known generally as Manchus. They were then considered the dominant race of the country now bearing their name (see Manchuria). They had then a considerable mixture of Chinese and Korean blood, and had developed a distinct nationality and kept their ancient Ural-Altaic language. In 1615 the Manchus were conquered by the Ming dynasty, and the Manchus retained their tribal nationalities and certain military organization. It was not until the early years of the 20th century that steps were officially taken to obliterate the distinction between the two races. The Manchus are a more robust race than the Chinese and somewhat taller. The population of northern China save that their eyes are horizontally set. They are a lively and enterprising people, but have not in general the intellectual or business ability of the Chinese. They are courteous in their relations with strangers. Their number is very large, and perhaps it is the largest in the world.

The family is generally large. The women’s feet are unbound; they twist their hair round a silver bangle placed cross-wise on the top of the head. The Manchus have no literature of their own, but as the language of the court Manchu has been extensively studied in China.

**Religion.**

The earliest traces of religious thought and practice in China point to a simple monotheism. There was a Divine Ruler of the universe, abiding on high, beyond the ken of man. This Power was not regarded as the Creator of the human race, as a Supreme Being to whom wickedness was abhorrent and virtuous conduct a source of joy, and who dealt out rewards and punishments with unerring justice, claiming neither love nor reverence from mankind. If a man did his duty towards his neighbour, he might pass his whole time on earth oblivious of the fact that such a Power was in existence; unless perchance he wished to obtain some good or attain some end, in which case he might seek to propitiate Him by sacrifice and prayer. There was no Devil to tempt man astray, and to rejoice in his fall; neither was there any belief that righteous behaviour in this world would lead at death to absorption in the Deity. To God, understood in this sense, the people gave the name Ti'en, which in the colloquial language was used of the sky; and when, in the first stages of the written character, it became necessary to express the idea of Ti’en, they did not attempt any vague picture of the heavens, but set down the name of a man. Perhaps about this period the name Shang Ti, or Supreme Ruler, came to be given to Ti’en as synonymous with Ti’en. But although the two terms were synonymous, and both may be equally rendered by “God,” there is nevertheless an important distinction to be observed, much as though Ti’en and Shang Ti were two Persons in one substance. Ti’en is far more an abstract Being, while Shang Ti parts rather of the nature of a personal God, whose anthropomorphic nature is much more strongly accentuated. Shang Ti is described as walking and talking, as enjoying the flavour of sacrifices, as pleased with music and dancing in his honour, and even as taking sides in warfare; whereas Ti’en holds aloof, wrapped in an impenetrable majesty, an ignotum pro mirifico. So much for religion in primeval days, gathered scrap by scrap from many sources; for nothing like a history of religion is to be found in Chinese literature.

Gradually to this monothestic conception was added a worship of the sun, moon and constellations, of the five planets, and of some noticeable individual stars (e.g. Canopus, which is now looked upon as the eye of the God of Longevity). Earth, too—Mother Earth—came in. Man had to worship her, and this worship was followed, indicated especially by the God of the Soil, and further distribuated among rivers and hills. Wind, rain, heat, cold, thunder and lightning, as each became objects of desire or aversion, were invested with the attributes of deities. The various parts of the house-door, kitchen-stove, courtyard, &c.—were also conceived of as sheltering some spirit whose influence might be benign or the reverse. The spirits of the land and of grain came to mean one’s country, the commonwealth, the state; and the sacrifices of these spirits by the emperor formed a public announcement of his accession, or of his continued right to the throne. Side by side with such sacrificial rites was the worship of ancestors, stretching so far back that its origin is not discernible in such historical documents as we possess. In early times only the emperor, or the feudal nobles, or certain high officials, could sacrifice to the spirits of nature; the common people sacrificed to their own ancestors and to the spirits of their own homes. For three days before performing such sacrifices, a strict vigil with purification was observed; and by the expiration of that time, from sheer concentration, to the sacrifice itself. The emperor had the power to see the spirits of the departed, and at the sacrifice next day seemed to know their movements and even the murmurs of their sighs. Ancestral worship in China has always been, and still is, worship in the strict sense of the term. It is not a memorial service in simple honour of the dead; but sacrifices are offered, and the whole ceremonial is performed that the spirits of former ancestors may be induced to extend their protection to the living and secure to them as many as possible of the good things of this world.

For Confucianism, which cannot, strictly speaking, be classed as a religion, see Confucius.
Around the scantly utterances of Lao Tzu or Lao-tse (q.v.; see also § Chinese Literature, §§ Philosophy) an attempt was made by later writers to weave a scheme of thought which should serve to satisfy the cravings of mortals for some definite solution of the problems of life. The catechism of Buddhism, a criterion which he called Tao, or the Way, from which is derived the word Taoism; and in his usual paradoxical style he had asserted that the secret of this Way, which was at the beginning apparently nonsensical, only became intelligible when it was comprehended and imparted, even by those who understood it. His disciples, however, of later days proceeded to interpret the term in the sense of the Absolute, the First Cause, and finally as One, in whose obliterating unity all seemingly distinct entities eventually melted away, and the doctrine of a single supreme reality, the One, the Absolute. This One, the source of human life, was placed beyond limits of the visible universe; and for human life to return thither at death and to enjoy immortality, it was only necessary to adhere to the precepts of the doctrine, as expounded by Lao Tzu. By and by, this One was to be regarded as a fixed point in the dazzling immensity of remote ether, around which circled for ever and ever, in the supreme glory of motion, the souls of those who had left the slough of humanity behind them. These transcendental notions were entirely correlative at a very early age by the induction of belief in an elixir of life, and later still by the practice of alchemical experiments. Opposed by Buddhism, which next laid a claim for a share in the profits of popular patronage, Taoism rapidly under the influence of the Gōshū and other religions of the Sui dynasty, which made Buddhism the state religion, and the earliest appearance of Buddhism in China dates from 217 B.C., when certain Shamans who came to proselytize were seized and thrown into prison. They escaped through the miraculous intervention of a temple, which came under the protection of the rulers, and opened their prison doors. Hu Kuan, a writer of the Sung dynasty, quotes in his Tung Chi passages to support the view that Buddhism was known in China some centuries before the reign of Ming Ti; among others, the following from the Wu-shu Ching Chi Chia: "These Buddhist writings had long been circulated far and wide, but disappeared with the advent of the Ch'in dynasty," under which (see § Chinese Literature, §§ History) occurred the burning of books and images, and the destruction of 4,000,000 images of Buddha, and most of the books. However, on the return of Ming Ti, as it was only subsequent to that date that Buddhism became a recognized religion of the people. It is certain that in A.D. 65 a mission of eighteen members was despatched to Korea to bring the religion of the people, and on their return, bringing Buddhist writings and images, and accompanied by an Indian priest, Kasiapmadanga, who was shortly afterwards by another priest, Goherana. A temple was built for these transmissions, now known to the Chinese, being also called the White Buddha, reached Canton, bringing with him the sacred bowl of the Buddhist Patriarchate, of which he was the last representative in the west and the first to hold office in the east. Summoned to Nanking, he offended the emperor by asserting that real merit lay, not in works, but solely in purity and wisdom combined. He therefore retired to Lo-yang, crossing the swollen waters of the Yangtsze on a reed, a feat which has ever since had a great fascination for Chinese painters and poets. The Buddha, a man, was not to be learnt from books, but that man should seek and find the Buddha in his own heart. Thus Buddhism gradually made its way. It had to meet first all of the bitter hostility of the Taoists; and the second and more serious foe was Buddhism as a state religion. Several emperors and empresses were intimations of the faith; one even went so far as to take vows and lead the life of an ascetic further insisting that to render full obedience to the Buddha was the duty of the emperor. "This is the Ick," they said, "but he is made of dough. Other emperors, instigated by Confucian advisers, went to the opposite extreme of persecution, closed all religious houses, confiscated their property, and closed the priests and monks to the people on pain of death. Buddhism, which had enjoyed comparative immunity from attack or restriction, and it now covers the Chinese empire from end to end. The form under which it appears in China is to some extent of local growth; that is to say, that in the local admixture of Buddhism and Taoism has been observed, by a progressive spirit, but without contradicting the inner significance of the teachings of Buddha, broadened its scope and assimilated other religious and philosophical beliefs, whenever this was done to the advantage of those who came within its influence. Such is the form of this religion which prevails in China, of which, however, the Chinese lama understand nothing. He goes to a temple, worships the gods with prostrations, lighted candles, burning incense, etc.; he may even listen to a service chanted in a foreign tongue and just as incomprehensible to the priests as to himself. He pays his fees and departs, absolutely ignorant of the history or dogmas of the religion he has just venerated, almost as ignorant of the language he has just learned, and there is now not much of it, is confined to a few of the more cultured priests.

The 7th century seems to have been notable in the religious history of China. Early in that century, Mahayana, or the religion of Zoroaster, based upon the worship of fire, was introduced into China, and in 621 the first temple under that denomination was built at Ch'iang-an in Shensi, then the capital. But it was done to the advantage of those who came within its influence. Thus the form of this religion which prevails in China, of which, however, the Chinese lama understand nothing. He goes to a temple, worships the gods with prostrations, lighted candles, burning incense, etc.; he may even listen to a service chanted in a foreign tongue and just as incomprehensible to the priests as to himself. He pays his fees and departs, absolutely ignorant of the history or dogmas of the religion he has just venerated, almost as ignorant of the language he has just learned, and there is now not much of it, is confined to a few of the more cultured priests. The true stock of the present Chinese Mahomedans was a small army of 4000 Arab soldiers sent by the caliph Abu Giafar in 755 to aid in putting down a rebellion. These soldiers had permission to settle in China, where they married native wives; and four centuries later, with the conquests of Genghiz Khan, large numbers of Arabs penetrated into the empire and settled in the Mahommedan community. Their descendants are now indistinguishable from the Chinese; they are under no civic disabilities, and are free to open mosques wherever they please, so long as, in common with Buddhists and Taoists, they exhibit the tablet of the emperor's sovereignty in some conspicuous place.

In A.D. 631 the Nestorians sent a mission to China and introduced Christianity under the name of the Luminous Doctrine. In 836 they were allowed to settle at Ch'iang-an, and in 843 a Nestorian church was established. The Church of the Nestorians, which is the only name by which a Nestorianist who is casually mentioned as a Persian, had presented a form of religion which his Majesty had carefully examined and had found to be in every way satisfactory, and that he was prepared to adopt it. The Church has been the subject of much dispute. The Chinese received the Nestorian mission with great enthusiasm. The Nestorians were allowed to set up a monastery, to be served by twenty-one priests. For more than a century after this, Nestorian Christianity seems to have flourished in China. In 781 the famous Nestorian Tablet:

1 Otherwise Abi Ja'far Ibn Mahommed-al-Mansur (see CALIPHATE, C. § 2).
giving a rough outline of the object and scope of the faith, was set up at Ch'ang-an (the modern Si-gan Fu), disappearing soon afterwards in the political troubles which laced the city in ruins, to be brought to light again in 1625 by Father Semedo, S. J. The genuine-ness of this tablet for many years in dispute. Voltaire, who and others of lesser fame regarding it as a pious fraud; but all doubts on the subject have now been dispelled by the exhaustive monograph of Pére Havret, S. J., entitled La Stele de Si-gan. The date of the tablet remained a secret; but a restoration in 1901 of the date on which it began to decay. Marco Polo refers to it as existing in the 13th century; but then it fades out of sight, leaving scanty traces in Chinese literature of ever having existed.

The Manichaean, worshippers of the Chaldaean Mani or Manes, who died about a.d. 274, appear to have found their way to China in the year 694. In 719 an envoy from Tokharestan reached Ch'ang-an, bringing a letter to the emperor, in which the visit was announced by an ambassador who accompanied the mission might be permitted to establish places of worship for persons of the Manichaean faith. Subsequently, a number of such churches were opened at various centres; but little is known of the history of religion, which is often confused by Chinese writers with Mazdaism, the fate of which it seems to have shared, also disappearing about the middle of the 9th century.

By the sect of those who take out the sinew, the Chinese refer to the Jews and to their ancient appearance in China; to make it shorter. Wild stories have been told of their journey to China seven centuries before the Christian era, after one of the numerous upheavals mentioned in the Old Testament; for having some connection with Pentateuchal legislation, shortly after the Babylonish captivity, and having founded a colony in Ho-nan in a.d. 72. The Jews really reached China for the first time in the year a.d. 1165, and were permitted to open a synagogue at Ch'ang-an. The Jews of the 13th century, however, have lived peaceably, enjoying the protection of the authorities and making some slight efforts to spread their tenets. There their descendants were found, a dwindling community, by the Jesuits Fathers of 1765, of preserving their ancient ritual and to whom, in 1804 the S. J. La Stele christienne de Si-gan jou (1878) (H. A. G.).

Christian missions. Both Roman Catholic and Protestant, are established in every province in China. Freedom to embrace the Christian religion is constitutionally guaranteed by the Chinese government since 1860, and as a rule the missionaries have free scope in teaching and preaching, though local disturbances are not infrequent. The number of the Roman Catholic Church in China is estimated to be, in 1902, "about one million"; in the same year the Protestant societies reckoned in all 250,000 church members. By the Chinese, Roman Catholicism is called the "Religion of the Lord of Heaven"; Protestantism the "Religion of Jesus," by which it is generally denominated in China see §§ History, and Missions, §§ China, Ed.).

Education and the Press. The educational system of China till nearly the close of the 19th century was confined in its scope to the study of Chinese classics. Elementary instruction was not provided by the state. The well-to-do engaged private tutors for their sons; the poorer boys were taught in small schools on a voluntary basis. No curriculum was compulsory, but the books used and the programs pursued followed a traditional rule. The boys were no schools for preparing the classics for further study in Confucianism. Then followed letter-writing and easy composition. This completed the education of the vast majority of the boys not intended for the public service. The chief merit of the system was that it developed the memory and the imitative faculty. For secondary education somewhat better provision was made, practically the only method of attaining eminence in the state being through the schools (see §§ Civil Service). At prefectoral cities and provincial capitals colleges were maintained at the public expense, and at these institutions a more or less thorough knowledge of the classics might be obtained. At the public examinations held periodically the exercises proposed were original poems and literary essays. Three degrees were conferred, Siu-tai (budding talent), Cich-i (promoted scholar) and Chin-shih (venerable scholar). The last degree was won by those who passed the final examination at Peking, and the successful candidates were also called metropolitan graduates.

The first education on western lines was given by the Roman Catholic missionaries. In 1852 they found a college for the education of native priests; they also founded and maintained many primary and some higher schools—mainly if not exclusively for the benefit of their own community. This educational enterprise was an example of the Roman Catholics, but a new departure, which has had a wide success, was initiated by the American Protestant missionary societies in founding schools—primary and higher—and colleges in which the teaching was provided free of charge, to either Chinese or non-Christian. Universities and medical schools have also been established by the missionary societies. They also initiated a movement for the education of girls and opened special schools for their instruction.

Missionary effort apart, the first step towards western education was the establishment of two colleges in 1861, one at Peking, the other at Canton in connexion with the imperial maritime customs. These gained enormously in strength as the result of the Russo-Japanese War, and in 1906 a new system, theoretically almost perfect, was established. The new system comprises the study of the Chinese language, literature and composition, modern science and mathematics, geography, history, gymnastics, drill, and, in the higher grades, political economy, and civil law.

By 1910 primary and secondary government schools for boys and girls began to be established in considerable numbers. In every province an Imperial University was also established. The Imperial University at Peking now reaches not only languages and Chinese subjects but also law, science, and mathematics. A medical school was founded at Peking in 1906 through the energy of British Protestant missionaries, and is called the Union Medical College. When in 1908, the United States, finding that the indemnity for the Boxer outrages awarded her was excessive, agreed to forgo the payment of £2,000,000, China undertook to spend an equal amount in support of students to America.

The general verdict of foreign observers on the working of the new system up to 1910 was that in many instances the teaching was ineffective, but there were notable exceptions. The best teachers, nearly always men of mean income, had been forced to migrate to Japan, employed as teachers who were often ignorant of Chinese and not as a rule very successful. (See further § History.) A remarkable indication of the thirst for western learning among the young people of China is the Peking Gazette, sometimes called the oldest newspaper in the world. It is not a daily newspaper, but a court gazette for publishing imperial decrees and such public documents as the government may wish to give out. It never contains original articles nor any discussion of public affairs. The first issue appeared in 1729 under the name of "China," and was published in both Chinese and English. It was not published during the Boxer period, having been suspended in 1900.

1 For a summary of Chang Chih-tung's treatise, see Changing China (1910 edition), chap. xxii.
2 It was announced in June 1910 that the throne had approved a recommendation of the Board of Education that English should be the official language for scientific and technical education, and that the study of English should be compulsory in all provincial scientific and technical schools.
AGRICULTURE

CHINA

Genuine native newspaper was published at Shanghai about 1870. It was the Shen Poo or Shanghai News, and was a Chinese speculation under foreign protection, the first editor being an Englishman. It was some years before it made much impression on the Chinese public, and it was for some years imitated, some published at Shanghai, some at other treaty ports and at Hong-Kong. In 1910 there were over 200 daily, weekly, or monthly journals in China. The effect of this mass of literature on the public is of first-rate importance.

The attitude of the central government towards the native press is somewhat undefined. Official registration of a newspaper is required before postal facilities are given. There are no press laws, but as each officer is a newspaper and as its output is often to the government and to the public, anything nothing to prevent him from summarily suppressing an obnoxious newspaper and putting the editor in prison. The emperor, under other reform edicts which provoked the coup d'état of 1898, declared the press free provided it was not directed to the overthrow of the government and that it was not to be used for obnoxious purposes. The empress-dowager revoked this decree, and declared that the public discussion of affairs of state in the newspapers was an impertinence, and ought to be suppressed. Nevertheless, the newspapers continued to flourish, and their outspoken criticism had a salutary effect on the public and on the government. The official classes seem to have become alarmed at the independent attitude of the newspapers, but instead of a campaign of suppression the method was adopted, about 1908, of bringing the vernacular newspapers under official control. This was a first-rate blow to the independent development of the press. The official newspapers have been purchased by the mandarins, with the result that at the beginning of 1910 there was said to be hardly an independent daily newspaper left in China. The use of government funds to support a newspaper that is not directed to the overthrow of the government is in itself a strong cause for alarm. Public opinion provoked strong protests from members of the Nanking provincial council at its first sitting in the autumn of 1909. The appropriation by the Shanghai Ta'oz' of moneys belonging to the Imperial Chinese government for subsidizing newspapers led to his impeachment by a censor and to the return of the moneys.

III. ECONOMICS

AGRICULTURE AND INDUSTRY

China is pre-eminently an agricultural country. The great majority of its inhabitants are cultivators of the soil. The holdings are in general very small, and the methods of farming primitive. Water is abundant and irrigation common over large areas. Stock-raising, except in Sze-ch'uen and Kiang-si, is of small importance. It is only practised to a small extent; there are few large herds of cattle or flocks of sheep, nor are there any large meadows, natural or cultivated. In Sze-ch'uen yaks, sheep and goats are reared in the mountains, and buffaloes and a fine breed of ponies on the plateaux. Cattle are extensively reared in the mountainous districts of Kiang-su and Kiang-nan. The camel, horse and donkey are reared in Chih-li. Forestry is likewise neglected. While the existing forests, found mainly in high regions in the provinces of Hu-nan, Fu-kien and Kwei-chow, are disappearing and timber has to be imported from the south, many large trees, both native and introduced, are planted. These are in the main for fruit, trees, which are grown in great variety, while hirculture is also a favourite pursuit.

The Chinese farmer, if his methods be primitive, is diligent and persevering. In the richer and more thickly populated districts terraces are raised on the mountain sides, and even the tops of lofty hills are cultivated. The nature of the soil and means of irrigation as well as climate are determining factors in the nature of the crops grown; rice and cotton, for example, are grown in the northernmost as well as in the most southern districts of China. This is, however, exceptional and each climatic region has its characteristic cultures.

The loess soil (see § Geology) is the chief element in determining the agricultural products of north China. Loess soil bears excellent crops, not only on the lower grounds, but on hills of altitudes of 6000 and 8000 ft. Wherever loess is found the peasant can live and thrive. Only one thing is essential, that is the annual rainfall. As, owing to the porous nature of loess, no artificial irrigation is possible, if the rain fails the crop must necessarily fail. The loess affords shelter such crops as the wheat, but the loess probably also accounts for the length of time it will go on bearing crops without becoming exhausted. The rainfall, penetrating deeply into the soil in the absence of stratification, comes into contact with the moisture retained below, which holds in solution whatever inorganic salts the soil may contain, and thus the loess has an indefinite store to draw upon.

There is no one dominant deposit in south China, where red sandstone and limestone formations are frequent. Cultivation here is generally carried on by small proprietors, and the soil is well suited for rice, but in the plains and river valleys the soil is excellently fertile, while the higher slopes of the mountains are also cultivated. In the north, however, but one crop, in general, can be raised in the year. In the central two-thirds of the empire three crops are raised yearly, and in the south, especially in the lower Huai basin, the crops are usually even more rapidly gathered. In the north, too, the farmer has frequently to contend with drought or with rain or floods; in the central and southern regions the weather is much milder. In the north region there are more setlements.

In the north of China wheat, barley, millet, buckwheat and maize are the staple crops. Beans and peas are also cultivated. Rice thrives in north-east Kiang-su, in some districts of Shan-si, the extreme south of Shan-tung and in parts of the Wu-hai plain. Tobacco is grown extensively in Kiang-su, Shantung and Kiang-nan. In Kiang-su and Shans-hui two crops are raised in favoured localities, cereals in spring and cotton or rice in summer. Tobacco and the poppy are also grown in several of the northern provinces, and the poppies, the tea, tobacco and rice are the chief crops. Wheat, maize and barley are also largely raised.

While rice does not, unlike tea and cotton, form the principal crop, yet in one province, the province of Yunnan, it is the staple product and forms an important item in the products of all the central and southern provinces. Regarding tea as a whole it forms the staple product and food of the country. Two chief crops, rice and tea, are specially grown in the uplands receiving ample water and the red rice cultivated in the uplands. Next to rice the most extensively cultivated plants are tea and cotton, the sugar-cane, poppy and bamboo. Besides the infinite variety of uses to which the wood of the bamboo is applied, its tender shoots and its fruit are articles of diet.

Fruit is extensively cultivated throughout China. In the northern provinces the chief fruits grown are pears, plums, apples, apricots, peaches, medlar, walnuts and chestnuts, and in Kan-suh and Kan-yang the peach is the most important crop. In Nan-si, S.W. Chih-li and Shantung the plum is the vine is cultivated; the grapes of Shan-si are reputed to produce the best wine in China. Oranges are also grown in the southern provinces of the north. The types of Chinese oranges are the oranges, litchi, mango, persimmon, banana, vine and pineapple, but the fruits of the northern regions are also grown. The coco-nut and other palms flourish on the southern coast.

As shown above, the poppy has been grown in almost every district of China. In 1906 it was chiefly cultivated in the following provinces: Yu-nan, Kwei-chow, Sze-ch'uen, Kan-suh, Shen-shan, Shan-si, Shan-tung, Ho-nan, Kiang-su (northern part) and Kweh-kien (southern part). Chinese literature in a book written in the first half of the 8th century A.D., and its medicinal qualities are referred to in the Herballis of the 9th century. It was not then nor for centuries later cultivated for its medicinal qualities in China. From this it appears that the Chinese did not use opium for its medicinal qualities but as a drug. Thus, it appears that the Chinese did not cultivate opium for its medicinal qualities but as a drug. Thus, it appears that the Chinese did not use opium for its medicinal qualities but as a drug. Thus, it appears that the Chinese did not use opium for its medicinal qualities but as a drug.
to work mines, and the mineral wealth has been very inadequately exploited. Mining operations are controlled by the Board of Commerce. In the board are rules and regulations respecting the constitution of mining and other companies. They contain many features against which foreign powers protested.

Coal, iron, copper and tin are the principal minerals found in China; these are worked in the provinces of Li-tsu-fu, Sinkiang, Hu-nan, Kwei-chow and Sze-chuen. Seven other provinces have also coal measures of more or less value. The lack of transport facilities as well as the aversion from the employment of foreign capital has greatly hindered the development of mining. Numerous small mines have been worked for a long period and have been abandoned when the prices were low. This is the case with principal local fields in this province, one lying in the basin of the Le River and yielding anthracite, and the other in the basin of the Wun River yielding bituminous coal. Both rivers drain into the Yellow River, and there is thus an easy outlet by water. The quality of the coal, however, is inferior, as the stratification has been much disturbed, and the coal-seams have been in consequence crushed and broken. The largest coalfield in China lies in the province of Hu-nan, and has been worked for a long time. The coal has been exported from time immemorial, but owing to the difficulty of transport they have attained only a limited local circulation. The whole of southern Shansi, extending over 30,000 sq. m., is one vast coalfield, and contains some of the largest and cleanest bituminous coal to last the world at the present rate of consumption for several thousand years. The coal-seams, which are from 20 to 36 ft. in thickness, rest conformably on a substratum of limestone. The strata dip in all directions, and are divided into easily accessible veins, built up by a mountain range of ancient granite formation running north-east and south-west, termed the Ho-shan. It is of anterior date to the lime- stone and coal formations, and has not affected the uniformity of the beds. But it is to be regretted that the deposit on the east side is anthracite, and that on the west side is bituminous. A concession to work coal and iron in certain specified districts in this area was granted to a British company, the Peking Syndicate, to work the coal in 1872, and the iron in 1872 and 1873. The syndicate built a railway in Shan-si from P'ing-yang to Tai-chow-fu, the centre of a vast coalfield, and connected with the main Peking-Hankow line; lines to serve coal mines have also been built in Hu-nan and other provinces. The earliest fact is that to the K'ai-p'ing collieries in the east of the province of Chih-li, the railway connecting the mines with the seaport of Taku. The coal at K'ai-p'ing is a soft bituminous coal with a large proportion of coke, and is generally worked in thin seams. A new coal seam has also been opened in the province of Hu-peh, about 50 m. below Hankow, and near the Yang-tze, in connection with iron ore. The ore of various qualities is found almost as widely diffused as coal. The districts where it is most worked lie within the coalfield of Shan-si, viz., at Tai-chow-fu and Ping- tung-chow. The ore is a mixture of clay iron ore and spathic ore, and is found in irregular deposits in the Coal Measures, and is easily smelted by the natives in crucibles laid in open furnaces. This region supplies nearly the whole of northern China, with the iron required for agricultural and domestic use. The output must be very considerable, but it is not forming any large estimate. The province of Sze-ch'uen also yields an abundance of iron ores of various kinds. They are worked by the natives in numerous places, but always on a small scale and for local consumption. The iron is smelted in small furnaces, and the iron ore is among them being a clay iron ore. Hu-nan, Fu-kien, Ch'eng-kiang and Shan-tung all furnish iron ores. Iron (found in conjunction with coal) is worked in Manchuria.

The industries of the provinces of Kwei-chow and Yunnan, where a rich belt of copper-bearing ores runs east and west across both provinces, and including south Sze-ch'uen. The chief centre of production is at the cities of Tung- fung, Kwei-chow, and Yunnan. Copper is worked as a government monopoly, private mining being nominally prohibited. The output is considerable, but no statistics are published by government. Rich veins of copper ore are also worked near the city of Tung-fung, which is the head-quarters of the industry being the city of Meng-tsze, which since 1905 has been connected with Hankow by railway. This is an important industry, the value of tin imported in 1905 being 562,000. Tin is also mined in Hai-nan and in Yunnan. Copper ore is exported from Hu-nan; petroleum is found in the upper Yang-tze region. Quick silver is obtained in Kwei-chow. Salt is obtained from brine wells in Shan-si and Sze-ch'uen, and by evaporation from sea water.

CHINA

Excellent kaolin abounds in the north-eastern part of Kiang-si, and is largely used in the manufacture of porcelain.

The Chinese government has opened small gold mines at Hai-nan, in which island silver is also found. A little gold-washing is done in the Li River and the upper Yang-tze, above Su-chow (Sui-fu), which here goes by the name of the "Goldsand" river. The amount so extracted is extremely small and hardly pays the labor involved in the resistances of the river. At least 300,000 tons have been found in quartz veins at Ping-tu, in Shang-tung, but hardly in paying quantities. There are silver mines in Yen-nan.

Manufactures.—The principal native manufactures before the competition of western nations made itself felt were—and apart from the growth of commerce and the introduction of new methods of production—those of porcelain and silk. The silks and gauzes of T'ai-chow and Nanking in the province of Kiang-su, and those of Hang-chow in Cheh-chiang, are highly esteemed throughout China. Silk-weaving is still carried on solely in native looms and chiefly in the cities named. The greater part of the silk spun is used in China, but a considerable export trade has grown up and 27% of the world's supply of raw silk is from China. The reeling of silks cocoons by European firms is supplied by the native methods. There are figures for winding silk at Shanghai, Canton, Chifu and other cities.

The most famous porcelain came from the province of Kiang-nan, the seat of the industry being the city of King-te-chen. Imperial works, and the more numerous and better known manufactories, have a constant demand for the best porcelain, and one factory is said to have produced as many porcelain vases and dishes as would form a wall 30 ft. high. The porcelain from this factory still possesses a high reputation, but the porcelain turned out is far from equaling in colour and finish that of former times. At the present day King-te-chen has but 16 furnaces and employs 160,000 workmen. The common rice bowls sold retail in the city of King-te-chen are worth about 17 cents. The value of the export sales is said to be about £5,000 yearly.

The spinning and weaving of cotton on hand-looms is carried on almost universally. Besides that locally manufactured, the whole of the large cotton-spun goods now consumed by the women of the household. Four-fifths of the clothing of the lower classes is supplied by this domestic industry. Of minor industries Indian ink is manufactured in Nung-hui and Sze-ch'uen, and certain kinds of porcelain, the manufacture of which is limited to a few factories or workshops. The production of Chinese porcelain equals that of the fine kinds of porcelains manufactured in France and Portugal, and perhaps of a few others. The manufactures of the Japanese, the Chinese in the interest of the Portuguese, and the Chinese in the interest of the Japanese, in Nanking, are known as Chinese or Japanese porcelain. A large variety of porcelain is also manufactured for the Chinese market, and is of the finest quality. The Chinese government is interested in the porcelain industry, and has erected porcelain manufactories on a large scale. The Chinese porcelain of the better grade is exported in vessels, and the price varies from £3 to £5 per hundred. The Chinese porcelain of the inferior grade is exported in cases, and the price varies from £1 to £2 per hundred.

Cotton, &c.

The manufacture of cotton in China has been carried on for centuries, and the market is estimated at 5,000,000,000 yuans of staple cotton. The Chinese have been engaged in the manufacture of yarn for the Chinese market, very little going being done. Chinese-grown cotton is used, the staple of which is short; only the coarser counts can be spun.

Agricultural and manufacturing industries in the provinces of Kiang-nan, Kien-nan, and Kiang-si, mills have been erected and are superseding native methods of weaving and spinning, and are engaged in the manufacture of yarn for the Chinese market, very little going being done. Chinese-grown cotton is used, the staple of which is short; only the coarser counts can be spun.

The foreign trade of China is conducted through the "treaty ports," i.e. sea and river ports and a few inland cities which by the "open ports" the treaties (1840) and subsequent treaties have been thrown open to foreign trade. The foreign trade is very small. The Nanking treaty recognized five ports only as open to foreigners—Canton, Amoy, Fu-chow, Ning-po and Shanghai. These places are the chief treaty ports in Manchuria being included: Amoy, Canton, Antung, Chao-nan, Chi'shan, Chungking, Ch'ang-yun, Ch'un-ch'ing, Fuchow, Funing (Santuau), Hang-chow, Hankow, I-ch'ang, Kang-moon, Kiao-k'ang, Kiu-k'ang, K'ing-chow, Kow-lou, Lappa, Lung-chow, Mengers, Mudien, Nanking, Nan-nan, Ning-ning, Peking, P'ing-tu, Shanghai, Shensi, Shiao, Shu-chow, Swatow, Szemao, Tungkow, Tientsin, Teng-yeueh, Wen-chow, Wu-chow, Wu-hu, Yen-chow.

2. In the 19th century, the Dutch traded to Formosa and the English to Amoy also. The Portuguese traded with Canton as early as 1517. For the early intercourse between Portugal and China see the introductory chapter of Donald Ferguson's Letters from Portuguese Captains in Canton (Bombay, 1882).
The progress of the foreign trade of China is set out in the following table. The values are given both in currency and sterling, but it is to be remarked that during the period when silver was falling, that is, from 1875 to 1892, the silver valuation represents much more accurately the variations in the volume of trade than the gold valuation. Gold prices fell continuously during this period, while silver prices have tended to rise, and the gold valuation is then more accurate. The conversion from silver to gold is made at the rate of exchange of the day, and therefore varies from year to year.

*This marked increase is partly owing to a more complete presentation of statistics; in 1903 an additional number of vessels were placed under the control of the imperial maritime customs.*

In 1897 the net imports were valued at £65,664,222 and the exports at £458,000. In 1898 China suffered from the general depression, and the export trade declined. In that year the imports were valued at £56,000,730, the exports at £58,889,020. The distribution of the trade among the various countries of the world is shown in the table which is given below. Hong-Kong is a port of transit. Of some years into China from it come originally from Great Britain, India, China.

In the miscellaneous class the chief items of exports in 1898 were beans, rice, and scows, £1,342,000; raw cotton, £9,379,000; hides, £1,000,000; straw, £1,000,000; furs and skin, £2,000,000; paper, £250,000; and clothing, £500,000. Sugar, tobacco, mats, and hemp, for export. The export of grain is extremely variable, and the pulse of commerce is not much for export. Of the tea exported in 1908 the greater portion went to Russia and Siberia, the United States, and Great Britain. There is a regular export of gold amounting on an average to about a million sterling per annum. A part of it would seem to be the hoardings of the nation brought out by the high price of gold in terms of silver, but a part is virgin gold derived from gold workings in Manchuria and the upper waters of the Amur river.

Customs duty is levied on exports, as well as imports, being assessed at rates based on a nominal 5% ad val. airport. Navigations.

Besides the over-sea trade China has a large coasting and river trade which is largely carried on by British and other foreign vessels. During the year 1908, 207,405 vessels, of 83,091,280 tons (68,000 being steamers of 79,005,525 tons), entered and cleared Chinese ports. Of these 28,445 vessels of 34,955,800 tons were British; 33,538 of 11,995,588 tons, Chinese vessels of foreign type; 103,124 of 4,947,272 tons, German; 3,121 of 546,515 tons, American; 1,946 of 3,810,571 tons, Russian; 938 of 3,916,289 tons, French; 245 of 1,950,635 tons, Norwegian.

**Communications.**

External communication is carried on by new railway lines crossing Central Asia, by the trans-Siberian railway, which is

---

increasingly used for passenger traffic, but chiefly by steamer, the
steamers being almost entirely owned by foreign companies. There is
regular and rapid communication with Europe (via the Suez canal
route) and with Japan and the Pacific coast of America. Other lines
in the case of the French and British railways, the Chinese-owned
steamers are those of the Chinese Merchants' Steam
Navigation Company, which has its headquarters at Shanghai.

Internal communications are by river, canal, road and railway, the
railways having undoubtedly assumed the most important function.
In 1856 the Chinese government agreed that all internal
waterways should be open to foreign and native steamers, and
in 1907 there were on the registers of the river ports for inland
waterways 609 steamers under the Chinese flag and 255 under
foreign flags.

Railways.—A short line of railway between Shanghai and Wusung
was opened in 1875. The fate of this pioneer railway may be
accounted for by the fact that it was the first line to be constructed
in China, but it had been completed without any regular permission from the Chinese
government, but it was hoped that, once finished and working, the
irregularity would be overlooked in view of the manifest
benefit to the people. This might have been accomplished
but for an unfortunate accident which happened on the
line a few months after it was opened. A Chinaman
was run over and killed, and this event, of course, intensified
the official opposition, and indeed threatened to bring about a
riot. The working of the line was stopped by order of the British
minister, and thereupon negotiations were entered into with a view
to selling the line to the Chinese government. A bargain was struck
sufficiently advantageous to the Western capitalists who had
the line; it was further agreed that, pending payment of the instalments which
were spread over a year, the line should continue to be worked by
the company. The expectation was that when the officials once got the
line in their hands, they would work it for the benefit of the Chinese
themselves, and on the initiative of Li Hung-chang. In 1886 a company was formed under official
patronage, and it built a short line, to connect the coal
mines of K'ing-chih with the mouth of the
Peiho river at Taku. The government next authorized the formation
of a Native Merchants' Company, under official control, to build a
line from Taku to Tientsin, which was opened to traffic in 1888. It
was completed as far as Peking. A British engineer, Mr Kinder,
was responsible for the construction of the railway. Meantime,
however, the extension had been continued north-east along the
coast to Nanking, and all connections were made, and the line
was opened to traffic in 1891.

The pioneer line from Taku was completed in 1890, and
Chinese officials had control of the railway. The line runs through Peking and is
considered a model of modern construction.

The first efforts of the Chinese government to improve
railway communication were directed to the
construction of a line from Tientsin to Peking, which was opened in 1892.

The era of co-operations.—The Chinese government, with authority to proceed forthwith with his railway,

True to his purpose, he at once set to work to construct iron-works at Hankow. Smelting furnaces, rolling mills, and all the machinery necessary for the production of steel were erected, and
the works were in full operation in 1895.

Several years were wasted over this preliminary work, and over
£1,000,000 sterling was spent, only to find that the works after all
were a failure. Steel rails could be made, but at a cost
twice that of American or European steel, and the
Chinese government was not able to afford the sum. After the Japanese War the hope of building railways with Chinese
capital was abandoned. A prominent official named Sheng Hsuan-tung was appointed director-general of railways, and empowered to enter into negotiations with foreign capitalists for
building railways. It was still hoped that at least the main
control would remain in Chinese hands, but the diplomatic pressure of
France and Russia caused even that to be given up, and Great
Britain and the United States were left with control of the foreign
railways in China remained in the hands of the various concessionaires.

But after the defeat of Russia by Japan (1904-1905) the
theory of the undivided Chinese control of railways was resuscitated.
The new spirit was exemplified in the contracts for the financing
and construction of three railways—the Canton-Kowloon line of
1907, and the Tientsin-Yangtsze and the Shanghai-Hankow-
Ningpo lines in 1908. In the first of these instances the railway
was mortgaged as security for the loan raised for its construction,
and its finance and working were to be modelled on the arrangements
made in the case of the Japanese Railway. While the
administration, vested in the Chinese government, was
supervised by a British agent and chief engineer. In the other
instances, however, no such security was offered; the Chinese
government simply invested in the lines, and the Europeans connected with
these works became simply Chinese employees. Moreover, in 1908 the Peking-Hankow line was redeemed from Belgian concessionaires,
for the loan of £5,000,000 being raised from Belgian bankers,
and transferred to the Rumanian and French banks. In that year there was much popular outcry against foreign
concessionaires being allowed to carry out the terms of their contracts, and the British and Chinese corporation in consequence
announced that they would make no further loans by railway
construction; in some instances the provinces proved more powerful than the central government, as in the case of the
Su-chow-Ning-po line, and notably in the matter of the Tientsin-
Peking-Hankow line. The capitalist Chinese government
overrode the central government, with the result that "for
wholesale jobbery, waste and mismanagement the enterprise acquired
unenviable notoriety in a land where these things are generally
avoided, and the management of the railways under Chinese control had, by
1910, become inefficient and corrupt. Nevertheless, so great was the
economic development following the opening of the line, that in China
railways were termed the "Vita of a nation",
and the construction of railways was considered an important centre of
national growth.

The main scheme of the railway systems of China is simple. It consists of lines, more or less parallel, running roughly north and
south, linked by cross lines with coast ports, or abutting on
some large navigable water system. The most important is the
railway line which runs through central China, from Hankow to Szechuan.

The railway system is as follows:

1. The line from Peking to Niu-chwang,
2. The line from Peking to An-tung (completed in 1905),
3. The line from Peking to Nanking,
4. The line from Peking to the Yangtse delta,
5. The line from Peking to the border of Manchuria.

One line goes south to Port Arthur; another south-east to An-tung (on the Yalu and Korea); a third south and west to Tientsin and
Nanking, and a fourth south and west to Canton and
Shanghai, and across the Peking-Hankow line, which will
serve as a nucleus for the development of the railways in the
south and west. The line from Peking to Shensi has been
completed, and the line to Szechuan is in progress.

Another main north and south railway parallel to, but east of,
the La-foo line and following more or less the route of the Grand
Canal, is designed to connect Tientsin, Su-chow (in Kiangsu),
Chin-kiang, Hankow, Nanking, and Shanghai. The southern section (Nanking, Shanghai, &c.) was opened in 1908.

The Tientsin-Ningpo railway connects at Chian Fu with the
Shantung lines.

Another main south and north line starts from Kiu-Kiang on the Yangtse
gulf and crosses the centre of Kiang-si province. It continues to Hankow, and
the line to Shao-Chow in Kwangtung province.

In the construction of the first section, Kiu-Kiang to Nanchang (1904-1905), $17,500,000 was raised, with a loan of
$12,500,000 from American and British banks.

In southern China the main line from Canton and Hankow (under construction) a line (120 m. long) runs from Canton to
Kowloon (opposite Hong-Kong), and there are local lines running through the interior of the province from Canton to
Fukien, and a line (50 m. long) from Haiphong in Tonking to Yunnan, the
capital of Yunnan, about 200 m. being in Chinese territory.

The French hold concessions for railways in Kwang-tung and
Kwangtung.
The British government has the right to extend the Burma railway system through Yunnan and north to the Yangtze. There are local lines in Hu-nan and Ho-nan which connect with the trunk line from Canton to Peking. The Peking-Kalgan line (122 m. long) is a distinct undertaking, but it is connected south-westward to Urga in Mongolia, and an eventual junction with the trans-Siberian railway in the neighbourhood of Lake Baikal is contemplated. This line would greatly shorten the distance between Moscow and Peking.

China is traversed in all directions by roads. Very few are paved of metalled surfaces; but many are broad enough to be travelled by government wheeled vehicles. The government spends nothing in keeping either the roads or canals in repair. The roads in several instances are subsidiary to the canals and navigable rivers as a means of communication. The ancient trade routes were twelve in number, viz.:—

1. The West river route (W. from Canton).
2. The Cheling Pass route (N.W. from Canton).
3. The Meiling route (N. from Canton).
4. The Min river route (N.W. from Fu-chou).
5. The Lower Yangtsze route (as far W. as Hu-peh and Hu-nan).
6. The Upper Yangtsze route (from Ichang to Sze-ch‘u-en).
7. The Kwei-chow route.
8. The Han river route (Hankow to Shen-si).
9. The Grand Canal (already described).
10. The Shan-si route.
11. The Kia-khta route.
12. The Manchurian route.

Of the routes named, that by the West river commands the trade of Kwang-si and penetrates to Yunnan and Burma. There is also a line running north from the Chinese railway stations at Tientsin and Kalgan to the Russian and Japanese systems in Manchuria, q.v. over 3000 m. of railway, and 1500 m. of trunk lines were under construction.

Roads, rivers, and canals.

Of the routes named, that by the West river commands the trade of Kwang-si and penetrates to Yunnan and Burma. There is also a line running north from the Chinese railway stations at Tientsin and Kalgan to the Russian and Japanese systems in Manchuria, q.v. over 3000 m. of railway, and 1500 m. of trunk lines were under construction.

The Chinese government maintains the said system. They are followed by the present dynasty, and the system is not yet complete. It is divided into two parts: a main line, which can be reached by railway from the French railway system in China, and a subsidiary line, which can be reached by railway from the French railway system in China. The main line, which can be reached by railway from the French railway system in China, is now opened to the general public.

Post and Telegraphs.—Every important city is now connected with the capital, and the service is reasonably efficient. In 1896 there were 1,600 m. of telegraph lines established with the British lines in Burma and the Russian lines in Siberia. The Great Northern Telegraph Company (Danish) and the Eastern Extension Telegraph Company (British) connect Shanghai by cable with Europe. A system of telephones in China is now in course of establishment. A postal service was established in 1863 under the general control of the Maritime Customs, but the service was not extensively used until 1876. An organized service for the conveyance of government despatches has existed in China for many centuries, and the postal system of every province is now in course of establishment. A postal service was established in 1863 under the general control of the Maritime Customs, but the service was not extensively used until 1876. An organized service for the conveyance of government despatches has existed in China for many centuries, and the postal system of every province is now in course of establishment.

IV. Government and Administration

Changes in the traditional form of government in China—an autocracy based on parental rule—were initiated in 1901 when a commission was appointed to study the forms of government in other countries. On the 1st of September 1906 an imperial edict was issued in which the establishment of parliamentary institutions in China was foreshadowed. In 1907 an advisory council—as a sort of stepping-stone to representative government—was established by another edict. On the 27th of August 1908 an edict announced the convocation of a parliament in the form of a national assembly. This condition of affairs dates back to the 27th of August 1908, when the first and only assembly was convoked in the form of a national assembly. The second and only assembly was convoked in the form of a national assembly. The third and only assembly was convoked in the form of a national assembly. The fourth and only assembly was convoked in the form of a national assembly. The fifth and only assembly was convoked in the form of a national assembly. The sixth and only assembly was convoked in the form of a national assembly. The seventh and only assembly was convoked in the form of a national assembly. The eighth and only assembly was convoked in the form of a national assembly. The ninth and only assembly was convoked in the form of a national assembly. The tenth and only assembly was convoked in the form of a national assembly. The eleventh and only assembly was convoked in the form of a national assembly. The twelfth and only assembly was convoked in the form of a national assembly. The thirteenth and only assembly was convoked in the form of a national assembly. The fourteenth and only assembly was convoked in the form of a national assembly. The fifteenth and only assembly was convoked in the form of a national assembly. The sixteenth and only assembly was convoked in the form of a national assembly. The seventeenth and only assembly was convoked in the form of a national assembly. The eighteenth and only assembly was convoked in the form of a national assembly. The nineteenth and only assembly was convoked in the form of a national assembly. The twentieth and only assembly was convoked in the form of a national assembly. The twenty-first and only assembly was convoked in the form of a national assembly. The twenty-second and only assembly was convoked in the form of a national assembly. The twenty-third and only assembly was convoked in the form of a national assembly. The twenty-fourth and only assembly was convoked in the form of a national assembly. The twenty-fifth and only assembly was convoked in the form of a national assembly. The twenty-sixth and only assembly was convoked in the form of a national assembly. The twenty-seventh and only assembly was convoked in the form of a national assembly.
is a fact into the causes of which it is worth while to inquire. We find it pictured in the records which make up the Book of History, and we find it enforced in the writings of the great apostle of patriarchal institutions, Confucius, and in all the other works which go to make up the Chinese Canon. But the Chinese reverence for these scriptures was viewed as the principal means of perpetuating the primitive form of Chinese imperialism. The contents of their pages formed the study of every schoolboy, and supplied the themes at the close of the day’s work, on which the pupils who sought an official career. Thus the mind of the nation was constantly and almost exclusively turned towards them, and their dogmas became part and parcel of the national training. The whole theory of government is the embodiment of parental love and filial piety. As the people are the children of the emperor, so is his the "Son of Heaven." In practice the arbitrary power of the emperor is tempered in several ways. Firstly, although the constitution conferred this absolute and undivided power on the emperor, it was not for his gratification but that he might exercise it for the good of his people. He rules by divine authority, and as the viceroy of heaven upon earth. If he rules corruptly or unjustly, Heaven will send disasters and calamity on the people as a reproof; if the rule becomes tyrannical, heaven may withdraw its favour entirely, and then rebellion may be justified. The Manchu dynasty came to the throne as foreign conquerors, nevertheless they believe in the Chinese tradition that the emperor is the son of Heaven, leaving Buddhism, Taoism, and any other form of worship to his subjects. The emperor’s sacrifices and prayers to heaven are conducted with great parade and ceremony. The chief of these state observances is that at the Temple of Heaven, which is held before sunrise on the morning of the 21st of December at the Temple of Heaven. The form of the altar is peculiar.

It consists of a triple circular terrace, 210 ft. wide at the base, 193 ft. wide at the top, and 128 ft. wide at the middle. The emperor, with his immediate suite, kneels in front of the tablet of Shangti (The Supreme Being, or Heaven), and faces the north. The platform is laid with marble stones, forming nine concentric circles; the inner circle consists of nine stones, cut so as to fit with close edges round the central stone, which is a perfect circle. Here the emperor kneels, and is surrounded first by the circles of the terrace and their enclosing walls, and then by the circle of the horizon. He then turns himself and to his court to be in the center of the circle, the touchstone of the imperial dignity. As a subject, he acknowledges in prayer and by his position that he is inferior to heaven, and to heaven alone. Round him on the pavement are the nine circles of as many heavens, consisting of nine stones, then eighteen, thirty-six, eighty-one, 144, 225, and 324, the central and in the square of nine, the favourite number of Chinese philosophy, is reached in the outermost circle of eighty-one stones.

On this occasion, also, a bullock of two years old, and without blood, is burnt at the altar. The emperor, with his immediate suite, kneels in front of the tablet of Shangti (The Supreme Being, or Heaven), and faces the north. The platform is laid with marble stones, forming nine concentric circles; the inner circle consists of nine stones, cut so as to fit with close edges round the central stone, which is a perfect circle. Here the emperor kneels, and is surrounded first by the circles of the terrace and their enclosing walls, and then by the circle of the horizon. He then turns himself and to his court to be in the center of the circle, the touchstone of the imperial dignity. As a subject, he acknowledges in prayer and by his position that he is inferior to heaven, and to heaven alone. Round him on the pavement are the nine circles of as many heavens, consisting of nine stones, then eighteen, thirty-six, eighty-one, 144, 225, and 324, the central and in the square of nine, the favourite number of Chinese philosophy, is reached in the outermost circle of eighty-one stones.

For his knowledge of public affairs the emperor is thus largely dependent upon such information as courtiers and high officers of state permit to reach him.2 The palace eunuchs have often exercised greater influence than they are allowed to. The Chinese monarchs have been strangely free from the natural jealousy of the nobility, and, in many cases, the ministerial career of high functionaries, or to that clique which for the time being has

---

1 The empress-consort is chosen by the emperor from the choice of girls selected by his ministers from the families of Manchu nobles. From the same candidates the emperor also selects secondary-empresses (usually not more than four). Concubines, not limited in number, are chosen from the daughters of Manchu nobles and free men. All the children are equally legitimate.

2 Recent emperors have been children at accession and have been kept in seclusion.

3 See "Democratic China" in H. A. Giles, China and the Chinese.
conduct of public affairs. They were: (1) Li Pu, the Board of Civil Appointments, controlling all appointments in the civil service from the rank of district magistrate upwards. (2) Hu Pu, the Board of Revenue, dealing with all revenues which reached the central government. (3) Board of Works, were spoken of collectively, the Board of War. It controlled the provincial forces. The Manchu forces were an independent organization attached to the palace. (5) Usung Pu, the Board of Punishments. It dealt with the criminal and judicial matters of the Manchu and Chinese. (6) Kung Pu, the Board of Works. Its work was limited to the construction of the control and repair of official residences.

As rearranged and enlarged there are now the following boards, given order of precedence:

1. Wai-see Pu.—This was established in 1901 in succession to the Tsung-li Yamên, which was created in 1861 after the Anglo-Chinese War in 1856 as a board for foreign affairs. Previous to that war, which excluded the right of foreign powers to have their representatives in Peking, all business with Western nations was transacted by provincial authorities, chiefly the viceroy at Canton. The only department at Peking which dealt specially with foreign affairs was that of the Chinese Board of Revenue. After the war, the Yamên was vested in the prince and ministers. For a long time the board had no real power, and was looked on rather as a buffer between the foreign envoys and the central government. The importance of foreign affairs, however, increased in the 20th century. The Japanese invasion of Manchuria in 1931 made the Yamên a more active body, and there are several of the most prominent men being members of the board. At the same time the Tsung-li Yamên was created. Two important offices were established in the provinces for dealing with foreign affairs, the special agencies, to embrace the consular and consular agents of the various foreign countries, and the Board of Peking (Pu), to be styled the Wai-see Pu, or “board of foreign affairs.”

3. Board of Civil Appointments.
4. Board of Home Affairs.
5. Board of Finance and Paymaster General’s Department.
6. Board of Ceremonies.
7. Army Board or Ministry of War (instituted 1906).* 8. Board of Judicature.
9. Board of Communications (instituted 1906).

11. Board of Dependencies.
12. Board of Education (instituted 1903).

The Censorate (Tu Ch’a Yuen).—An institution peculiar to China. The constitution provides a paid body of men whose duty it is to form the empire of all facts affecting the welfare of the people and the conduct of government, and in particular to keep an eye on the manner in which those in high office are employed in the collection of taxes and the expenditure of money. The members of the Censorate, known as Ch’ing Ch’ing (Council of Censors), are taken from the middle and upper classes and are chosen by the emperor from among those who have succeeded in the imperial examinations. The emperor may suspend the office of censor for any time he sees fit, or he may dismiss the office of censor at his pleasure, and the remuneration of the office is limited only to the salary of a civil commissioner or provincial judge, and the commissioner of education (this last post being created in 1905). The treasurer controls the finances of the whole province, receiving the taxes and paying the salaries of the officials. The governor is the chief executive and the grain controller are the only other officials whose authority extends over the whole province. Each province is subdivided into prefectures ruled by prefects, and each prefecture into districts ruled by county magistrates. Each magistrate, or official through whom the people in general receive the orders of the governor, is called an fang-tsi, or circuit, the official at the head of which is called a Ta-t’ai. Each town and village has its small official governing body of magistracy. The officials appointed to hold office for three years, but they may be re-appointed once, and in the case of powerful viceroys they may hold office for a prolonged period. Another rule is that no official is ever appointed to a post in the province of his birth; a rule, however, did not apply to Peking. Peking is a special province because it is the residence of the emperor. The announcement of new appointments is made by the central government and given out to local and provincial papers, the number of members allotted to each province varying from 30 (Kirin province, Manchuria, and two others) to 140 in Chih-li. The franchise was restricted, but the returns for the first elections showed that only a few per cent were given even to the victorious candidates. The first meetings of the assembly were held in October 1909.

*Thus in 1910 Prince Ching, president of the grand council, was, for the third time, impeached by censors, being denounced as an “old treacherous minister,” who filled the public service with a crowd of men as unworthy as himself. The censor who made the charge was stripped of his office (see The Times of the 30th of March 1910).

1 Yamén is the name given to the residences of all high officials, Tsung-li Yamén = the bureau for managing eachindigenous affairs.

2 An edict of the 15th of July 1909 created a naval and military advisory board. Up to that time the navy was controlled by the viceroys at Canton, Nanking, Fuzhou, and Tientsin, the viceroys at Canton and Tientsin being ministers superintendent of the southern and northern ports respectively.
The Civil Service.—The bureaucratic element is a vital feature in the government of China, the holding of office being almost the only road to distinction. Officials are by the Chinese collectively Kwoon (rulers or magistrates) but known to foreigners as mandarins (q.e.). The mandarins are divided into nine degrees, distinguished by the buttons worn on the top of their caps. These are as follows:—first and highest, a plain red button; second, a flowered red button; third, a transparent blue button; fourth, an opaque blue button; fifth, an uncoloured glass button; sixth, an opaque white shell button; seventh, a plain gilt button; eighth, a gilt button with flowers in relief; ninth, a gilt button with engraved flowers. The buttons indicate simply rank, not office. The peacock feathers worn in their hats are an order granted as reward of merit, and indicate neither rank nor office. The Yellow Jacket similarly is a decoration, the most important in China.

The ranks of the civil service are recruited by means of examinations. Up to the beginning of 1906 the subjects in which candidates were examined were purely Chinese and literary with a smattering of history. In 1906 this system was modified and an official career was opened to candidates who had obtained honours in an examination in western subjects (see Education). The old system is so closely identified with the life of China that some space must be devoted to a description of it.

As a general rule students preparing for the public examination read with private tutors. There were a few high schools or universities, and some learning was obtained from provincial capitals, and at some other places, there were indeed institutions termed colleges, supported to some extent from public funds, where advanced students could prosecute their studies; but before the turn of the century the official education was in the hands of the prefects to which he belonged. This was termed the Siud'sai, or licentiate's, and was merely a qualification to enter for the higher examinations. The number of licentiate degrees to be given was, however, strictly limited; those who had failed in these were rarely tried again, which they might do as often as they pleased. There was no limit of age. Those selected next proceeded to the great examination held at the capital of each province, once in three years, before examiners sent from Peking for the purpose. Against the new, who passed with the least success, the number of those who could qualify for the public service was very limited. Out of 10,000 or 12,000 competitors only some 300 or 350 could obtain degrees. The others, as before, must go back and try again. This degree, termed Chi jen, or provincial graduate, was the first step in the way of the mandarin of and of itself qualified for the public service, though it did not immediately nor necessarily lead to active employment. The third and final examination took place at Peking, and was open to provincial graduates from all parts of China. Out of the many candidates for this final degree, which was held triennially, some 350 to 350 succeeded in obtaining the degree of Chin shih, or metropolitan graduate. These were the finally selected men who became the officials of the empire.

Several other doors were, however, open by which admission to the ranks of bureaucracy could be obtained. In the first place, to encourage scholars to persevere, a certain number of those who failed to reach the chi jen, or second degree, were allowed, as a reward of repeated efforts, to get into a special class from which selection was made for the higher examinations. Out of the same number of competitors, the three who obtained the most votes in the three examinations of the class were given the right to nominate the sons and grandchildren of distinguished deceased public servants without examination. And, lastly, by a system of recommendation, young men from favoured institutions or men who had received some sort of training were given the right to enter and compete for substantive appointment. The necessities of the Chinese government also from time to time compelled it to throw open a still wider door of entry into the civil service, namely, admission by purchase. During the period of Lin Piao, when the number who passed was cut down to 500 or 600, money was required to purchase admission, although the amount was much less than that charged for the civil service examination, and the purchase was usually made by the father of the candidate at his expense. As a result of this policy, the country has been saddled with thousands of titular officials far in excess of the number of appointments to be given. Deserving men were kept waiting for years, while inferior and less capable officials were enabled to live comfortably because they had money wherewith to bribe their way. Nevertheless the purchase system admitted into the service a number of men free from that bigoted adherence to Confucian doctrine which characterizes the literary classes, and more in touch with modern public life.

All candidates who succeed in entering the official ranks are eligible for active employment, but as the number of candidates is far in excess of the number of appointments a period of weary waiting ensues. A few of the best scholars get admitted at once into the Hanlin college or into one or other of the boards at Peking. The rest are drafted in batches to the various provinces to await their turn for appointment as vacancies occur. During this period of waiting they are termed "expectants" and draw no regular pay. Occasional service, however, falls in their way, as when they are commissioned as temporary police in fighting districts, which they perform as Wet yang or deputies of the prefect. Not infrequently it may be abridged by recommendation or purchase, and it is generally supposed that this last lever must invariably be resorted to secure any lucrative local appointment. A poor but promising official is often forced to cut his letters of introduction short and to go to look for himself the means to bribe his way to the top. Apointments to the junior provincial posts are usually left to the provincial government, but the central government reserves to itself the right to order and transfer to the post of any assistant who may be considered necessary. The lucrative posts of customs, taot'ai, at the treaty ports are usually made direct from Peking, and the official selected is neither necessarily nor usually from the provincial staff. It would perhaps be safe to say that this appointment has hitherto always been the result of a pecuniary arrangement of greater or less magnitude.

During the first five years (1906-1910) of the new method, by which candidates for the civil service were required, in addition to the classical examination, to be subject to a form of extra-territorial examination, great efforts were made in several provinces to train up a better class of public official. The old system of administration had many theoretical excellences, and there had been notable instances of upright administration. But the system which forbade Chinese courts to try Chinese cases for more than three years made it the selfish interest of every office-holder to get as much out of the people within his jurisdiction as he possibly could in that time. This corruption in high places had a thoroughly disreputable effect on the discipline of the lower classes. Chinese probity in business relations with foreigners is proverbial, the people generally set little or no value upon truth, and this has led to the use of torture in the courts of justice; for it is argued that where the truth can be obtained from the mouths of a man who has taken an oath it must be the result of torture.

Justice.—The Chih-Hsien or district magistrate directs ordinary police cases; he also coroner and sheriff, he hears suits for divorce and criminal cases, and can commit persons to gaol. The penalty for taking a case first to a higher court is fifty blows with the bamboo on the naked thigh. Appeal from the Hsien court lies to the Fu, or prefectural court, and thence cases may be taken to the higher courts in the empire. There is no appeal to the emperor. The penalty for bribery is death by beheading.

Justice is administered by the prefect, by the magistrate of the town or village, and by the jen shih or assistant in the office of the prefect. The highest court in the empire is the Peking court of the first instance, and appeals are made thence to the Chih-Hsien. There is no appeal from the Chih-Hsien to the Fu or higher courts, the penalty being death by beheading.

For capital offences the usual mode of inflicting the extreme penalty of the law are—in bad cases, such as parricides, "cutting to pieces," and for less aggravated crimes either strangulation or dismemberment. The culprit who is condemned to death is fastened to a cross, and while thus suspended cuts are made by the executioners on the fleshly parts of the body; and he is then beheaded. Strangulation is reserved for lesser degrees of guilt, it being considered less disgraceful. If it has not been granted to a criminal of rank thus to meet his end, a silken cord is sent to him at his own home. No explanatory message is considered necessary, and he is left to consume his own doom. Popular sentiment regards capital punishment as disgraceful, not of death. Consent generally makes the executioner a wonder-fully expert in the performance of his office. No block or resting-place for the head is used. The neck is simply outstretched to its full length by the aid of an assistant, and one blow invariably leaves the head unrestrained.

The laws are in accord with the principle which regards the family as a unit. Thus there is no bankruptcy law—if a debtor’s own estate will not suffice to pay his debts the deficiency must be made good from the general fund of the immediate family are imprisoned. By analogy if one member of a party commits an offence and the guilty person cannot be detected, the whole party must suffer. Foreigners residing in China are not subject to the jurisdiction of the law, to themselves. As a result extra-territorial rights were sought by European powers. They were secured by Russia as early as 1689.

2. See The Times of the 28th of February 1919.
but it was not until 1843 that any other nation acquired them. In
that year Great Britain obtained the right to try British subjects by
its own courts, a right secured in more explicit terms by the United
States and France in 1844. Now eighteen powers, including Japan, 
have secured such courts for the trial of their own subjects according to
the laws of their native lands. Mixed courts have also been estab-
lished, that is, a defendant is tried in the court of his own nationality, 
the court giving its decision under the supervision of a representa-
tive of the victorious power. China, however, refused equal terms
sent representatives to sit on the bench of consular courts, but, as
the Europeans lack confidence in the administration of Chinese justice, no
suit brought by a foreigner against a Chinese is decided without the
presence of an assessor of the plaintiff’s nationality.

Defence.—The Chinese constitution in the period before
the reform edicts of 1905-1906 provided for two independent sets of
military organizations—namely, the Manchu army and the provincial
militia. On the eve of the Manchu dynasty in 1644 the victorious troops, composed mainly of
Manchus, but including also Mongols and Chinese, were permanently
quartered in Peking, and constituted a hereditary national army. They
were nominally, however, a part of the Manchu, and all the descendants of the members of other
nationalities were enrolled. They form the bulk of the population of the
Tatar city of Peking. Each adult male was by birth enrolled to be an
officer, and had a right to draw rations—i.e., his allowance of the tribute rice,
whether on active service or not. Detachments from one or other of
the banners were stationed as garrisons in the chief provincial
centres, Fuchow, Hangchow, &c., and their descendants still occupy the same positions. As
the garrisons did not change, the Manchu garrisons both in the capital and in the provinces
had long become quite efficient. In the capital, however, the petite
of the Chinese army formed the special corps termed the
Peking Field Force. Its nominal strength was about 20,000 men,
armed and drilled after the European fashion, and fairly well paid.
There were other corps of picked Manchus better paid and better
armed, than the ordinary soldier, and it was computed that in 1901
the Manchu army in or near Peking could muster 40,000, all more
or less efficient.

The second organization was termed the army of the Green
Standard, being the Chinese provincial forces. The nominal strength
was about 130,000, over 90,000 for each province. The
actual strength was about one-third of this. They were enrolled to
keep the peace within their own province, and resembled a militia
or local constabulary rather than a national army. They were generally
under the direction of their local provincial authorities.

The only real fighting force which China possessed at the beginning of
the 20th century was made up of certain special corps which were
not provided for in the constitution, and consequently were not
used for foreign service. These were the Manchu army, composing
the actual strength was about one-third of this. They were enrolled to
keep the peace within their own province, and resembled a militia
or local constabulary rather than a national army. They were generally
under the direction of their local provincial authorities.

the actual strength was about one-third of this. They were enrolled to
keep the peace within their own province, and resembled a militia
or local constabulary rather than a national army. They were generally
under the direction of their local provincial authorities.

An imperial edict of the 15th of July 1909 created a
naval and military advisory board. Niumg Sound, centrally
situated on the coast of Chek-kiang, was chosen as naval base, and
various naval establishments were to be established; a navigation
school at Chiu, an engineering school at Whampoa, a school for
artificers at Fuchow, and a gunnery and musketry school at Niumg Sound. A superior naval college was founded at Peking,
and the training schools were thus better time organized, and a training
class was procured and put under the command of a British naval officer. Some twenty- 

five or thirty small vessels were built in the course of as many years,
but gradually the whole organization was allowed to fall into decay.

The fleet was in 1899 in a very dilapidated condition, and in
1909 valueless to the Chinese government. There were also naval
yards at Nanking, Wuchang, Canton and Chêngtu.

Forts.—A great number of forts and batteries have been erected
along the coast and at the entrance to the principal rivers. Chief
among these, now that the Taku forts formerly commanding the
entrance to Tientsin have been demolished, are the Kiangyin forts
in the mouths of the Peiho, the Min forts at the entrance of the
Fuchow rivers, and the Louen forts at the entrance to the Canton river.
These are supplied with heavy armament from the Krupp and Armstrong factories.

Finance.

In fiscal matters, as for many other purposes, the Chinese
empire is an agglomeration of a number of quasi-independent
units. Each province has a complete administrative staff,
collects its own revenue, pays its own civil service, and other
costs, and is placed upon it. Out of the surplus contributed
towards the expenses of the central government a sum which
varies with the imponderables of the moment to that latter and with
its own comparative wealth or poverty. The imperial
government does not collect directly any part of the revenues, unless
the imperial maritime customs be excepted, though these too,
may be passed through the books of the provincial authorities.

It has hitherto been extremely difficult to obtain anything
like trustworthy figures for the whole revenue of China, for the
reason that no complete statistics are published by the central
government at Peking. The only available data are, first, the
returns published by the imperial maritime customs for the duties
levied on foreign trade; and, secondly, the memorials sent to
Peking by the provincial authorities on revenue matters, certain
of which are selected from time to time in the Peking Gazette.

A few of the old native customs stations, which are deemed
perquisites of the imperial court, may also be excepted, as, for
instance, the native custom-house at Canton, the Kwan on the
Grand Canal, and various stations in the neighbourhood of Peking.

The production of a budget in 1915 was promised in one of
the reform edicts of 1908.
These are usually fragmentary, being merely reports which the governor has received from his subordinates, detailing, as the case may be, the yield of the land tax or the likin for his particular district, with a dissertation on the causes which have made it more or less than for the previous period. Or the return may be one detailing the expenditure of such and such a department, or reporting the transmission of a sum in reply to a requisition of the board of revenue, with a statement of the source from which it has been met. It is only by collating these returns over a long period that anything like a complete statement can be made up. And even then these returns do not represent anything like the total of taxation paid by the people, but, as far as they go, they may be taken to represent the volume of taxation on which the Peking government can draw revenue.

The following table, taken from a memorandum by Sir Robert Hart, dated the 25th of March 1901, shows the latest official estimate (up to 1910) of the revenue and expenditure of China:

<table>

A calculation of revenue from all sources published by the Shanghai Shen Pao in 1908, apparently derived from official sources, gives a total revenue of 105,000,000 taels, or about 15 million sterling. This sum is obviously less than the actual figures. In 1907 Mr H. B. Morse, commissioner of customs and statistical secretary in the inspectorate general of customs, drew up the following table based on the amounts presumed to be paid by the tax-payer:

<table>
<thead>
<tr>
<th></th>

</tbody>
</table>

Mr Morse adds that the grand total shown, taels 284,150,000, is an obviously insufficient sum on which to maintain the fabric of government in an empire like China, but it has been reached by calculations based on a few known facts and ... is offered as throwing some light on a subject veiled in obscurity."

1 In this article the word is used as a standard is the Haikwan (i.e. customs) tale, worth about 3s. It fluctuates with the value of silver.
2 Roughly £43,000,000.
3 Trade and Administration of the Chinese Empire (1910), p. 118.

The service of the foreign debt, together with the pressure of other needs—such as the cost of education and the army—made modulation felt that previously the chaos of the Chinese fiscal system. A scheme to reform the national finances was promulgated under an edict of the 11th of January 1909, but it did not appear to be of a practical character.

Sources of Revenue. 1. Land Tax.—In China, as in most oriental countries, the land has from time immemorial been the mainstay of the revenue. In the early years of the present dynasty there was levied a land tax called the "tael" as a basis of the assessment levied in 1712 the two were amalgamated, and the whole burden was thrown upon land, families not possessing land being therefor exempted from taxation. At the same time it was decreed that the amount of land tax paid as the leviable salt is silver, and interest for all time coming. It would appear from the reports that the proceeds have been kept as far as the central government has been concerned. In all its many financial difficulties it does not seem ever to have tried to increase the revenue by raising the land tax. The amount of tax leviable on each plot is entered on the title deed, and, once entered, it cannot be changed. The tax on all land is thus stated to be so much in silver and so much in rice, wheat or whatever the principal crop may be. Except in two provinces, however, the tax on land is levied in silver, with a fixed proportion paid in gold. The value of the grain forwarded (generally called tribute rice) is estimated at taels 6,500,000. The total collection in silver, as reported by the provincial officials in 1910, was to taels 25,000,000. The total yield of the land tax, therefore, is taels 31,500,000, or say £4,625,000. It will readily be granted that for such a large country as China this is a very insignificant one. In India the land tax yields about 20 million and China has undoubtedly a larger cultivated area, a larger population, and soil that is on the whole more fertile; but it is certain that this sum by no means represents the amounts actually paid by the cultivators. It is the sum which the various vendors and collectors have to account for and remit in hard cash. But as nothing is allowed them for the costs of collection, they add on a percentage beforehand to cover the cost. This they usually do by declaring the taxes leviable in silver, and charging in copper "cash," which is the only currency that cures in the markets, and by fixing the rate of exchange to suit themselves. Thus while the market rate is, say, 1500 cash to the tael, they declare by general proclamation that for tax-paying purposes cash will be received at the rate of 3500 or 4000 to the tael. Thus while the yield of land tax in silver remains the same it is in effect doubled or trebled, and, what is worse, no return is made or account required of the extra sums thus levied. Each magistrate or collector is in effect a farmer. The tax standing opposite the name of his district is the sum which he is bound to return under penalty of dismissal, but all sums which he can scrape together over and above the perquisites of office less his necessary expenses. Custom, no doubt, sets bounds to his capacity; if he were too far he would be taken; but he may safely say there never is any reduction, what change can be effected being in the upward direction. According to the best information obtainable a moderate estimate of the sums actually paid by the cultivators in China is an estimate of the area under cultivation should give for the eighteen provinces £19,000,000 as being actually levied, or more than four times what is returned. 2. The Salt Duty.—The trade in salt is a government monopoly. Only licensed merchants are allowed to deal in it, and the import of foreign salt is forbidden by the treaties. For the purpose of salt administration China is divided into seven or eight main circuits, each of which has its own sources of production. Each circuit has distinctly defined boundaries, and salt produced in one circuit is not allowed to be consigned into or sold in another. There are great differences in price between the several circuits, but the consumer is not allowed to buy in the cheapest market. He can only buy from the licensed merchant in the district, and if he were to transact his business outside the circuit he would be deprecated from procuring supplies except at the depot to which they are consigned. Conveyance from one circuit to another is deemed smuggling, and subjects the article to confiscation.

Thus is levied under the name of heads, the drug being a duty proper, payable on the issue of salt from the depot, and the second being the salt levied on transit or at the place of destination. The two together amount on an average to about taels 150 per picul of grain. The total collection amounts to taels 13,500,000 (£2,025,000) per annum. The total consumption of salt for all China is estimated at about 25 million piculs, or nearly 9 million tons, which is at the rate of about one and a half cattel of salt per head of the people. The tonnage of salt of 150 per picul in 1899 was uniformly levied and returned, and the revenue would be £237 million taels instead of 133. In this calculation, however, no allowance is made for the cost of collection. 3. Likin on General Merchandise.—By the term likin is meant the tax on all kind of merchandise, payable on importation and exportation. It is levied at 12 scho (2.5 per cent.) on the value of all goods under two heads, the drug being a duty proper, payable on the issue of salt from the depot, and the second being

4 Temporary reductions are granted in provinces affected by rebellion, drought or flood.
a tax on inland trade levied while in transit from one district to another. It was originally a war tax imposed as a temporary measure to meet the military expenditure required by the Taiping and Mahomedan rebellions of 1850–1870. It is now one of the most annoying items in the revenue list. It is also the only import duty, objectively considered, which can be levied without being very objectionable as a tax can be, and is equally obnoxious to the native and to the foreign merchant. Tolls or barriers are erected at frequent intervals along all the principal routes of trade, whether by land or water, and on every one of them there is a duty, levied not by the provincial government but by the collector of the district, to the profit of his own purse.

The individual levy is small, but over a long transit it may amount to 15 or 20%. The objectionable feature is the frequent stoppages with overhauling of cargo and consequent delay, which may amount to several days in some cases. The problem of how to levy a single payment of one-half the import duty, but this stipulation is but indifferently observed. It must also be remembered, per contra, that dishonest foreign merchants will take out passes to cover waterways, and thus evade the duty, levied in some cases on foreign vessels.

The treaty rights lie in the fact that the likin revenue is claimed by the provincial authorities, and the transit duties when commuted belong to the central government, so that the former are interested in opposing the commutation by every means in their power. As a further means of neutralizing the commutation they have devised a new form of impost, viz. a terminal tax which is levied on the goods after the termination of the transit. The amount and frequency of likin taxation are fixed by provincial legislation—that is, by a proclamation of the governor. The levy is authorized in general terms by an imperial decree, but all details are left to the local authorities.

The yield of this tax is estimated at taels 13,000,000 (£95,000), the superannuated duty actually paid by the merchants, the balance being costs of collection.

4. Imperial Maritime Customs.—The maritime customs is one department of finance in China which is managed with probity and energy. The government has an adequate body of trained officers. The duties are levied at the port of entry, a standard rate being fixed by the treaty for each article of commerce. The individual levy is small, but over a long transit it may amount to 15 or 20%.

By arrangement between the British and Chinese governments, the foreign customs are levied at the ports of entry, a standard rate being fixed for each article of commerce. The individual levy is small, but over a long transit it may amount to 15 or 20%

In 1865, the total revenue from the foreign customs continued to be similar to that prevailing in the maritime customs before the introduction of foreign supervision. Each collector is constituted a farmer, bound to account for a fixed minimum sum, but practically at liberty to retain all he may collect over and above. If he returns more he may claim certain honorable rewards for extra diligence, but he generally manages to make out his accounts so as to show a small surplus, and no more. Only imperfect and partial regulations of the operation of the so-called junk trade, the duties on which are still levied by the native customs officers. By arrangement between the British and Chinese governments, the foreign customs are levied at the ports of entry, a standard rate being fixed for each article of commerce.

6. Duty on Native Opium.—The collection of the duty on opium is in the hands of the provincial officials, but they are required to render separate account of duty and likin collected on the drug, and to hand the sum at the disposal of the board of revenue at Peking. The annual import into China of Indian opium used to amount to about 50,000 chests, the exact amount of opium imported in 1904 being 54,750 piculs, on which the Chinese government levied a duty of 10 taels per chest (£1,000), a rate fixed by the Chinese government in 1804. The number of chests that entered China was about 24 million. Compared with this sum, the amount actually levied, or at least returned by the local officials as levied, was insignificant. The returns gave a total levy for all the eight provinces of only 1,000,000 taels 2,066,000 in 1902 to 3,990,000 in 1906.

7. Miscellaneous.—Besides the main and regular sources of income, the provincial officials levy sums which must in the aggregate amount to a very large figure, but which hardly find a place in the returns of the provincial revenue. Special taxes, land revenues, land revenue, and the probable number of sales, that this item alone often yields a return of between one and two millions sterling. Practically the whole of this is absorbed in office expenses.

Under this heading should also be included certain items which though not deemed part of the regular revenue, have been so often resorted to that they cannot be left out of account. These are the indemnity demands, the war indemnity levies, and the general revenue from the government for the benefit of the central government and the provincial authorities to increase their annual remittances by a few thousand taels.
FRANCE—The Franco-Russian loan of 3,400,000,000 (15,830,000) was raised in Paris. Two Anglo-German loans, each of 15,000,000 (one in 1896, the other in 1898) were raised through the Hong Kong and Shanghai Bank. The Franco-Russian loan bears 4% interest, the first Anglo-German 5% the second 4%. The loan to China of 1896, secured on the revenue of the Imperial Northern railway, bore 3.5% interest.

Between 1899 and 1907 (both years inclusive) 12,200,000 was raised on loan for railway purposes. The charges on the first 5,000,000 were secured on the revenue of the Imperial Northern railway, the interest being 5%. The same interest was secured on the other loans, one for £1,000,000 in which the Hong Kong government was concerned, which bears 4% interest.

The notes issued by the cities or towns are called tael notes, and they are mainly restricted to the cities. They bear the same rate of interest as the tael. They are issued primarily to give the city or town a sort of independent character.

V. HISTORY

(A)—European Knowledge of China up to 1615.

China as known to the Ancients.—The spacious seat of ancient civilization which we call China has been distinguished by different appellations, according as it was reached by the southern sea-route or by the northern land-route traversing the longitude of Asia. In the former aspect the name has nearly always been some form of the name Sin, Chin, Sinoe, China. In the latter point of view the region in question was known to the ancients as the land of the Seres, to the middle ages as the empire of Cathay. The name of Chin has been supposed (doubtfully) to be derived from the dynasty of Tsin, which a little more than two centuries before the Christian era enjoyed a vigorous existence, uniting all the Chinese provinces under its authority, and extending its conquests far beyond those limits to the south and the west. The mention of the Chinas in ancient Sanskrit literature, both in the laws of Manu and in the Mahabharata, has often been supposed to prove the application of the name long before the predominance of the Tsin dynasty. But the coupling of that name with the Duradhas, still surviving as the inhabitants of China, has led to the belief that those Chinas were a kindred race of mountaineers, whose name as Shinas in fact likewise remains applied to a branch of the Dard races. Whether the Sinus of the prophet Isaiah should be interpreted of the Chinese is probably not susceptible of any decision; by the context it appears certainly to indicate a people of the extreme east or south. The name probably came to Europe through the Arabs, who made the China of the farther east into Sin, and perhaps sometimes into Thin.

The thin of the author of the Periplus of the Erythraean Sea, who appears to be the first writer to employ the name in this form (i.e. assuming Max Müller’s view that it belongs to the 1st century); hence also the Sinas and Thinas of Ptolemy.

It has often indeed been denied that the Sinae of Ptolemy really represented the name of the idea of Marcus of Heraclea (a mere condenser of Ptolemy), when he tells us that the ‘nations of the Sinae lie at the extremity of the habitable world, and adjoin the eastern Terrna Incognita’, with that of Cosmas, who speaks of the ‘two continents of Cathay and Sinae’. We may question the application to China, that ‘beyond this there is neither habitation nor navigation’;—we cannot doubt the same region to be meant by both. The fundamental error of Ptolemy’s conception is his idea of a large basin of the sea surrounding that part of the earth, but that sea should displace the Chinese empire. But considering that the term of Sin has come down among the Arabs from time immemorial as applied to the Chinese, considering that in the work of Ptolemy this name certainly represented the farthest known East, and considering how inaccurate are Ptolemy’s configurations and longitudines much nearer home, it seems almost as reasonable to deny the identity of his India with ours as to deny that his Sinae were Chinese.
The Seres is indeed familiar to the Latin poets of the Augustan age, but always in vague way, and usually with a regard to Central Asia and the farther East. We find, however, that the first endeavours to assign more accurately the position of this people, which are those of Mela and Pliny, gravitate distinctly towards China in its northern aspect as the true ideal insusceptible of any modification. Moreover, China was the remotest East as Asia was occupied by the races (proceeding from south to north). Indians, Seres and Scythians; just as in a general way we might still say that eastern Asia is occupied by the Indies, China and Tartary.

Puteaux, of the Chineses of the Seres, the former for the chief city, the latter for the country of the Seres, and as usual defines their position with a precision far beyond what his knowledge justified—the necessary result of his system. Yet even his definition of the Seres, though as correct as the situation of the people with this name indicated the Chinese empire in its northern aspect, for he carries it eastward to the 180th degree of longitude, which is also, according to his description, in a lower latitude the eastern boundary of the Sinae. Ammianus Marcellinus devotes some paragraphs to a description of the Seres and their country, one passage of which is startling at first sight in its seeming allusion to the Great Wall, and in this sense it has been rashly interpreted by Lassen and by Reinard. But Ammianus was merely converting Ptolemy’s dry tables into fine writing, and speaks only of an encircling rampart of mountains within which the spacious and happy valley of the Seres lies. It is true that Ptolemy makes his Serica extend westward to Imaus, i.e. to the point where the empire of the West seems to extend at that epoch, and we find Lieut. John Wood in 1838 speaking of “China” as lying immediately beyond Pamir, just as the Arabs of the 8th century spoke of the country beyond the Jaxartes as “Sin,” and as Ptolomy speaks of Serica as extending immediately beyond the Indus.

If we fuse into one the various notices of the Seres and their country, omitting anomalous statements and manifest fables, the result will be somewhat as follows: “The region of the Seres is a vast and populous country, touching on the east the ocean and the limit of fertile and habitable country, and extending west to Imaus and the confines of Bactria. The people are civilized, mild, just and frugal, eschewing collisions with their neighbours, and even shy of close intercourse, but not averse to dispose of their own products, of which their land is rich, but which they also destroy in large furs, and iron of remarkable quality.” That is manifestly a definition of the Chinese.

That Greek and Roman knowledge of the true position of so remarkable a nation had at best been somewhat hazy is nothing wonderful. And it is worthy of note that the view entertained by the ancient Chinese of the Roman empire and its inhabitants, under the name of Tso-hsin, had some striking points of analogy to those views since. It is merely converting Ptolemy’s dry tables into fine writing and speaking only of an encircling rampart of mountains within which the spacious and happy valley of the Seres lies. There can be no mistake the fact that in this case also the great object was within the horizon of vision, yet the details ascribed to it are often far from being true characteristics, being only the accidents of its outer borders.

The Medieval Cathay.—“Cathay” is the name by which the Chinese empire was known to medieval Europe, and it is in its original form (Kítai) that China is still known in Russia and to most of the nations of Central Asia. West of Russia this name has long ceased to be a geographical expression, but it is associated with a remarkable phase in the history of geography and commerce. The name first became known to Europe in the 13th century, when the vast conquests of Jenghiz Khan and his house drew a new and more attentive attention to the East. For centuries past the northern provinces of China had been detached from indigenous rule, and subject to northern conquerors. The first of these foreign dynasties was of a race called Khitás issuing from the basin of the Sungari river, and supposed (but doubtfully) to have been the blood of the modern Tunguses. The rule of this race endured for two centuries and originated the application of the name Khitát or Khitátí to northern China. The dynasty itself, known in Chinese history as Liao, or “Iron,” disappeared from China 1213, but the name remained attached to the territory which they had ruled.

The Khitán were displaced by the Nyúch (Nyúchák or Chirchák) race, akin to the modern Manchus. These reigned, under the title of Kin, or “Golden,” till Jenghiz and his Mongols invaded them in turn. In 1234 the conquest of the Kin empire was completed, and the dynasty extinguished under Ogúi (Ogutái), the son and successor of Jenghiz Khan. Forty years later, in the reign of Kublai, grandson and ablest successor of Jenghiz, the Mongol rule was extended over southern China (1270), which till then had remained under a native dynasty, the Sung, holding its royal residence in a vast and splendid city, now known as Hang-chow, but then as Ling-nan, or more commonly as King-tse, i.e. the court. The southern empire was usually called by the conquerors Montai (or as some of the old travellers write, Mongi), a name which western Asians seem to have identified with Mächén (from the Sanskrit Maháchén), one of the names by which China was known to the traders from Persian and Arabic ports.

The conquest of Jenghiz and his successors had spread not only over China and the adjoining East, but westward also over all northern Asia, Persia, Armenia, part of Asia Minor and Russia, threatening to deluge Christendom. Though the Mongol wave retired, as it seemed almost by an immediate act of Providence, when Europe lay at its feet, it had levelled or covered all political barriers from the frontier of Poland to the Yellow Sea, and when western Europe recovered from its alarm, Asia lay open, as never before or since, to the inspection of Christendom. Princes, envoys, priests—half-missionary, half-envoy—visited the court of the great khan in Mongolia; and besides these temporary visitors, there was a permanent immigration of a character which carried a vast number of persons from various classes of human life into the great depths of Asia. “..."Tis worthy of the grateful remembrance of all Christian people,” says an able missionary friar of the late age (Riccold of Monte Croce), “that just at the time when God sent forth into the Eastern parts of the world the Tatars to slay and to be slain, He also sent into the West his faithful and blessed servants, Dominic and Francis, to enlighten, instruct and build up in the faith.” Whatever on the whole may be thought of the world’s debt to Dominic, it is to the two mendicant orders, but especially to the Franciscans, that we owe a vast amount of information about medieval Asia, and, among other things, the first mention of Cathay. Among the many strangers who reached Mongolia were (1225-1247) John de plano Carpini and (1253) William of Rubruk (Rubraquis) in French Flanders, both Franciscan friars of high intelligence, who happily have left behind them reports of their observations.

Carpini, after mentioning the wars of Jenghiz against the Kítái, goes on to speak of that people as follows: “Now these Kítái are heathen men, and have a written character of their own... They seem, indeed, to be kindly and polished folks enough. They have no beard, and in character of countenance have a considerable resemblance to the French, on account of their complexion and the expression of their visages.” But they are not so broad in the face. They have a peculiar language. Their betters as craftsmen in every art practised by man are not to be found in the whole world. Their country is very rich in corn, rice, salt, and gold, and almost everything which enters into commerce or opportunity carried a vast number of persons from various classes of human life into the great depths of Asia. “..."Tis worthy of the grateful remembrance of all Christian people,” says an able missionary friar of the late age (Riccold of Monte Croce), “that just at the time when God sent forth into the Eastern parts of the world the Tatars to slay and to be slain, He also sent into the West his faithful and blessed servants, Dominic and Francis, to enlighten, instruct and build up in the faith.” Whatever on the whole may be thought of the world’s debt to Dominic, it is to the two mendicant orders, but especially to the Franciscans, that we owe a vast amount of information about medieval Asia, and, among other things, the first mention of Cathay. Among the many strangers who reached Mongolia were (1225-1247) John de plano Carpini and (1253) William of Rubruk (Rubraquis) in French Flanders, both Franciscan friars of high intelligence, who happily have left behind them reports of their observations.
We have no evidence that either in the 13th or 14th century Cathayans, i.e. Chinese, ever reached Europe, but it is possible that some did, at least in the former century. For, during the campaigns of Hulagu in Persia (1256-1265), and the reigns of his successors, Chinese engineers were employed on the banks of the Tigris, and Chinese astrologers and physicians could be consulted at Tabriz. Many diplomatic communications passed between the Hulaguid Ilkhans and the princes of Christendom. The former, as the great khan's liege men, still received from him their seals of state; and two of their letters which survive in the archives of France exhibit the vermillion impressions of those seals in Chinese characters—perhaps affording the earliest specimen of that character which reached western Europe.

Just as the Polos were reaching their native city (1295), after an absence of a quarter of a century, the forerunner of a new series of travellers was entering southern China by way of the Indian seas. This was John of Monte Corvino, another Franciscan who, already some fifty years of age, was plunging single-handed into that great sea of paganism to preach the Gospel according to his lights. After years of uphill and solitary toils converts began to multiply; coadjutors joined him. The Papal See became cognizant of the harvest that was being reaped in the Far East. It made Friar John archbishop in Cambaluc (or Peking), with patriarchal authority, and sent him batches of suffragan bishops and preachers of his own order. The Roman Church spread; churches and Minorite houses were established at Cambaluc, at Zayton or Tsun-chow in Fu-kien, at Yang-chow and elsewhere; and the missions flourished under the patronage of the great khan, as the Jesuit missions did for a time under the Manchu emperors three centuries and a half later.

Archbishop John was followed to the grave, about 1328, by mourning multitudes of pagans and Christians alike. Several of the bishops and friars who served under him have left letters or other memoranda of their experience, e.g. Andrew, bishop of Zayton, John of Otrar, and a history of the missions by a later Persian, a certain Florin, whose fame as a pious traveller, won from the theos populi at his funeral a beatification which the church was fain to seal. The only ecclesiastical narrative regarding Cathay, of which we are aware, subsequent to the time of Archbishop John, is that which has been gathered from the recollections of Giovanni de' Marignolli, a Florentine Franciscan, who was sent by Pope Benedict XIII. with a mission to the great khan, in return for one from that potentate which arrived at Avignon from Cathay in 1338, and who spent four years (1342-1346) at the court of Cambuluc as legate of the Holy See. These recollections are found dispersed incoherently over a chronicle of Bohemia which the traveller wrote by order of the emperor Charles IV., whose chaplain he was after his return.

But intercourse during the period in question was not confined to ecclesiastical channels. Commerce also grew up, and flourished for a time even along the vast line that stretches from China, for centuries, to the ports of Cheh-kiang and Fu-kien. The record is very fragmentary and imperfect, but many circumstances and incidental notices show how frequently the remote East was reached by European traders in the first half of the 14th century—a state of things which it is very difficult to realize when we see how all those regions, when reopened to knowledge two centuries later, seemed to be discoveries as new as the empires which, about the same time, Cortes and Fizarro were conquering in the West.

This commercial intercourse probably began about 1310-1320. John of Monte Corvino, writing in 1305, says it was twelve years since he had heard any news from Europe; the only Western stranger who had arrived in all that time being a certain Lombruck (probably one of the Pechots) who got hard and gold home; and yet this was one of the most incredible blasphemies about the Roman Curia and the order of St Francis. Yet even on his first entrance to Cathay Friar John had been accompanied by one Master Peter of Lucolongo, whom he describes as a faithful Christian man and a great merchant, and who seems to have remained many years at Peking. The letter of Andrew, bishop of Zayton (1326), quotes the opinion of Genoese merchants at that port regarding a question of exchange. Oddor, who was in Cathay about 1342-1347, refers to a fleet which had brought the goods of the great city of Cansay (i.e. King-sze, or Hang-chow) to the many persons whom he had met at Venice since his return, who had themselves been witnesses of these marvels. And Marignolli, some twenty years later, found attached to one of the convents at Zayton, in Fu-kien, a fondaco or factory for the accommodation of the Christian merchants. In the monkish annals of the time, the commerce of Cathay is mentioned in the highest importance and frequency of European trade with Cathay, of which silk and silk goods formed the staple, is to be found in the commercial hand-book (c. 1330) of Francesco Balducci Pegolotti, a clerk and merchant in the Great Father. That book has thrown to the ground about that time by its dealings with Edward III. of England. This book, called by its author Libri di divisinamenti di Paesi, is a sort of trade-guide, devoting successive chapters to the various ports and markets of his time, detailing the nature of imports and exports, the prices of goods, and the usual sums of weight, measures and money. The first two chapters of this work contain instructions for the merchant proceeding to Cathay; and its evidence, from the terms used, that the road thither was by far the most frequented. Pegolotti had derived his information. The route which he describes lay by Anzov, Astrakhan, Khiva, Otrar (on the Jaxartes), Almalk (Gulja in Illy), Kan-chow (in Kan-su), and so to Hang-chow and Peking. It is a long and arduous journey, for which he informs the visitor, and the Elbe money of Cathay. That the ventures on this trade were not insignificant is plain from the example taken by the author to illustrate the question of expenses on the road, it is a journey which both the merchant investing in goods there to the amount of some £12,000 (i.e. in actual gold value, not as calculated by any fanciful and fallacious equation of values).

Of the same remarkable phase of history that we are here consulting there were also many direct and immediate writers. The establishment of the Mongol dynasty in Persia, by which the great khan was acknowledged as lord paramount, led (as we have seen already in part) to a good deal of intercourse. And some of the most remarkable of these writers were contemporaries of the Mongol princes, have told us much about Cathay, especially Rashiduddin, the great minister and historian of the dynasty (died 1318). We have also in the book of the Moorish traveller Ibn Batuta, who visited China about in 1325, a very curious and in great part true notices, though it is not possible to give credence to the whole of this episode in his extensive travels.

About the time of the traveller first named the throne of the degenerate descendants of Jenghis began to totter to its fall, and we hear that the great khan would not listen to the wise advice of the later Persian writer, Fegolotti, who thought that the name and the titles by which the great khan was acknowledged would be more acceptable to the Chinese than to the Turks; missions and merchants alike disappear from the field. We hear, indeed, once and again of ecclesiastics despatched from Avignon, but they go forth into the darkness, and are heard of no more. The church in Cathay, which in 1341 had recovered its grasp over Central Asia; the Nestorian Christianity which once had so widely been vanishing, and the new rulers of China reverted to the old national policy, and held the foreigner in awe; until at length the Mongol dynasty was overthrown, and Cathay with those cities of which the old travellers had told such marvels, Cambaluc and Cansay, Zayton and Chinkalan. And when the veil rose before the Portuguese and Spanish explorers of the 16th century, we know that some of the old French names had more than faded out. The great khan, who ruled over China, Peking, Hangchow, Chinchin, Canton. Not only were the old names forgotten, but the fact that those places had ever been known before was forgotten also. Gradually new missions were sent forth from Avignon and other courts, and new emblems were made, and new vicarates constituted; but the old Franciscan churches, and the Nestorianism with which they had battled, had alike been swallowed up in the ocean of pagan indifference. In time the work of those early missions was forgotten; the principal work performed at that time was the translation of Catholic sculpture; and when the intelligent missionaries called Marco Polo to mind, and studied his story, one and another became convinced that Cathay and China were one.
CHINA

HISTORY

Cathay as a supposed separate entity may be considered to come to an end with the journey of Benedict Goës, the layjesuit. This admirable person was, in 1603, despatched through Central Asia by his superiors in India with the specific object of determining whether the Cathay of old European writers and of modern Manisseans was not a distinct region from that China of which parallel marvels had now for some time been recounted. Benedict, as one of his brethren pronounced his epitaph, "seeking Cathay found Heaven." He died at Suchow, the frontier city of China, but not before he had ascertained that China and Cathay were the same. After the publication of the narrative of his journey (in the Expeditions Christiana apud Sinas of Trigault, 1615) inexplicable ignorance alone could continue to distinguish between them, but such ignorance lingered many years longer.

(B)—Chinese Origins.

Chinese literature contains no record of any kind which might justly allow us in assuming that the nucleus of the nation may have immigrated from some other part of the world; and the several ingenious theories pointing to Babylon, Egypt, India, Khotan, and other seats of ancient civilization as the starting-points of ethnical wanderings must be dismissed as untenable. Whether the Chinese were seated in their later homes from times immemorial, as their own historians assume, or whether they arrived there from abroad, as some foreign scholars have pretended, cannot be proved to the satisfaction of historical critics. Indeed, anthropological arguments seem to contradict the idea of any connexion with Babylonians, Egyptians, Assyrians, or Indians. The earliest hieroglyphics of the Chinese, ascribed by them to the Shang dynasty (second millennium B.C.), betray the Mongol character of the nation that invented them by the decided obliquity of the human eye wherever it appears in an ideograph. In a pair of eyes shown in the most ancient pictorial or sculptural representations in the west, the four corners may be connected by a horizontal straight line; whereas lines drawn through the eyes of one of the oldest Chinese hieroglyphics cross each other at a sharp angle, as shown in the accompanying diagrams:

This does not seem to speak for racial consanguinity any more than the well-known curled heads and bearded faces of Assyrian sculptures as compared to the straight-haired and almost beardless Chinese. Similarities in the creation of cultural elements may, it is true, be shown to exist on either side, even at periods when mutual intercourse was probably out of the question; but this may be due to uniformity in the construction of the human brain, which leads man in different parts of the world to arrive at similar ideas under similar conditions, or to prehistoric connexions which it is as impossible for us to trace now as it is the origin of mankind itself. Our standpoint as regards the origin of the Chinese race is, therefore, that of the a.pgistic. All we can do is to reproduce the tradition as it is found in Chinese literature. This tradition, applying to the very earliest periods, may be more or less subject to invention, yet it has its historical importance. Supposing it were possible to prove that none of the persons mentioned in the Bible from Adam down to the Apostles ever lived, even the most sceptical critic would still have to admit that the history of a great portion of the human race has been materially affected by the belief in the examples of their alleged lives. Something similar may be said of the alleged earliest history of the Chinese with its model emperors and destatable tyrants, the accounts of which, whether based on reality or not, have exercised much influence on the development of the nation.

The Chinese have developed their theories of prehistoric life. Speculation as to the origin and gradual evolution of their civilization has resulted in the expression of views by authors who may have reconstructed their systems from remnants of ancestral life revealed by excavations, or from observation of neighbouring nations living in a state of barbarism. This may account for a good deal of the reception found in the Chinese mythological and legendary narratives, the personal and chronological part of which may have been invented merely as a framework for illustrating social and cultural progress. The scene of action of all the prehistoric figures from P’an-ku, the first human being, down to the beginning of real history has been laid in a part of the world which has never been anything but Chinese territory. P’an-ku’s epoch, millions of years ago, was followed by ten distinct periods of sovereigns, including the “Heavenly emperors,” the “Terrestrial emperors,” and the “Human emperors,” the Yu-châu or “Nest-builders,” and Sui-jôn, the “Fire Producer,” the Prometheus of the Chinese, who borrowed fire from the stars for the benefit of man. Several of the characteristic phases of cultural progress and social organization have been ascribed to this mythological period. Authors of less fertile imagination refer them to later times, when the heroes of their accounts appear in shapes somewhat resembling human beings rather than as gods and demi-gods.

The Chinese themselves look upon Fu-hi as their first historical emperor; and they place his lifetime in the years 2852–2738 B.C. Some moderns conceive of a series of eight emperors, and we see him depicted as a human figure with a fish tail something like a mermaid. He is credited with having established social order among his people, who, before him, had lived like animals in the wilds. The social chaos out of which Chinese society arose is described as being characterized by the absence of family life; for “children knew not only their mothers and not their fathers.” Fu-hi introduced marriage; and in so doing he placed man as the husband at the head of the family and abolished the original matriarchate. This quite corresponds with his views on the dualism in natural philosophy, of which he is supposed to have laid the germs by the invention of the so-called pa-kua, eight symbols, each consisting of three parallel lines, broken or continuous. The continuous lines represented the male element in nature; the broken ones, the female. It is characteristic that the same ruler who assigned to man his position as the head of the family is also credited with the invention of that natural philosophy of the “male and female principles,” according to which all good things and qualities were male, while their less held the the opposite, whereas females, such as heaven and earth, sun and moon, day and night, south and north. If these traditions really represent the oldest prehistoric creations of the popular mind, it would almost seem that the most ancient Chinese shared that naïve sentiment which caused our own forefathers to invent gender. The difference is that, with us, the conception survives merely in the language, where the article or suffixes mark gender, whereas with the Chinese, whose language does not express gender, it survives in their system of metaphysics. For all their attempts at fathoming the secrets of nature is based on the idea that male or female powers are inherent in all matter.

To the same Emperor Fu-hi are ascribed many of the elementary inventions which raise man from the life of the brute to that of a social being. He taught his people to hunt, to fish, and to keep flocks; he constructed musical instruments, and replaced a kind of knot-writing previously in use by a system of hieroglyphics. All this cannot of course be considered as history; but it shows that the authors of later centuries who credited Fu-hi with such inventions were not quite illogical in starting from the matriarchal chaos, after which he is said to have organized society with occupations corresponding to those of a period of hunting, fishing and herding. This period was bound to be followed by a further step towards the final development of the nation’s social condition; and we find it quite logically succeeded by a period of agricultural life, personified in the Emperor, Shôn-nung, supposed to have lived in the twenty-eighth century B.C. His name may be freely translated as “Divine Labourer”; and to him the Chinese ascribe the invention of agricultural implements, and the discovery of the medicinal properties of numerous plants.
The historical emperor was Huang-ti, the "Yellow emperor," according to the literal translation. Shih-ma T'sien, the Hereditary King, begins his history with him; Fu-hi and Shên-nung are referred to in texts much older than this historian, though many details relating to their alleged reigns have been added in later times. Huang-ti extended the boundaries of the empire, described as being originally confined to a limited territory near the banks of the Yellow river and the present city of Si-an-fu. Here were the sites of cities used as capitals of the empire under various names during long periods since remote antiquity. To Huang-ti, whose reign is said to have commenced in 2704 according to one source and in 2491 according to another, are ascribed most of the cultural innovations which historians were not able otherwise to locate within historical times. Under Huang-ti we find the first mention of a nation, the Han-yü, who occupied the north of his empire and with whom he is represented to have engaged in warfare. The Chinese identify this name with that of the Hsiung-nu, their old hereditary enemy and the ancestors of Attila's Huns. Even though the details of these legendary accounts may deserve little confidence, they must have been (At least in part) ascribed to the Hsiung-nu occupying the northern confines of China, were the ancestors of the Hsiung-nu tribes, well known in historical times, a scion of whose great khans settled in territory belonging to the king of Sogdiana during the first century B.C., levied tribute from his neighbours, the Alans, and with his small but warlike horde initiated that era of migrations which led to the overrun China by the Central-Asian Tartars.

Fu-hi, Shên-nung, and Huang-ti represent a group of rulers comprised by the Chinese under the name of San-huang, i.e. "The Three Emperors." Although we have no reason to deny their existence, the details recorded concerning them contain enough in the way of improbabilities to justify me in considering them as mythical creations. The chronology, too, is apparently quite fictitious; for the time allotted to their reigns is much too long as a term of government for a single human life, and, on the other hand, much too short, for it our measure it by the cultural progress said to have been brought about in it. Fu-hi's period of hunting life must have lasted many generations before it led to the agricultural period represented by the name Shên-nung; and this period in turn could not possibly have led within a little more than a hundred years to the enormous progress ascribed to Huang-ti. Under the later ruler a regular board of historians is said to have been organized with Ts'ang-k'ii, as president, who is known also as Shi-huang, i.e. "the Emperor of Historians," the reputed inventor of hieroglyphic writing placed by some authors into the Fu-hi period and worshipped as T'ao-shên, i.e. "God of writing," to the present day. Huang-ti is supposed to have been the first builder of temples, houses and cities; to have regulated the calendar, to which he added the intercalary month; and to have devised means of traffic by cars drawn by oxen and by boats to ply on the lakes and rivers of his empire. His wife, known as the "lady of Si-ling," is credited with the invention of the several manipulations in the rearing of silkworms and the manufacture of silk. The invention of certain flutes, combined to form a kind of reed organ, led to a definite study in music and in the arts of singing and dancing. During this period of the Reset, objects with the necessary accuracy a system of weights and measures had to be devised. Huang-ti's successors, Shau-hau, Chuan-hu, and Ti-k'ü, were less prominent, though each of them had their particular merits.

The Model Emperors.—Most of the stories regarding the "Three Emperors" are told in comparatively late records. The Shu-k'ing, sometimes described as the "Canon of History," our oldest source of pre-Confucian history, supposed to have been edited by Confucius himself, knows nothing of Fu-hi, Shên-nung, and Huang-ti; but it being a particularly historical of Ta-ku and his successors Shun. Yau and Shun are probably the most popular names in Chinese history as taught in China. Whatever good qualities may be imagined of the rulers of a great nation have been heaped upon their heads; and the example of their lives has at all times been held up by Confucianists as the height of perfection in a sovereign's character. Yau, whose reign has been placed by the fictitious standard chronology of the Chinese in the years 2357–2258, and about 200 years later by the less extravagant. "Annals of the Bamboo Books," is represented as the patron of certain astronomers who had to watch the heavenly bodies; and much has been written about the reputed astronomical knowledge of the Chinese in this remote period. Names like Deguineus, Gauhul, Biot and Schlegel are among those of the investigators. On the other side are the sceptics, who maintain that later editors interpolated statements which could have been made only with the astronomical knowledge possessed by their own contemporaries. According to the Four Wicked ones "to distant territory. One of the names T'ou-t'ie, i.e. "Glutton"; called also San-miau, T'ou-t'ie is also the name of an ornament, very common on the surface of the most ancient bronze vessels, showing the distorted face of some ravenous animal. The San-miau as a tribe are said to have been the forefathers of the Tangutans, the Tibetans and the Miao-tzu in the south-west of China. This legend may be interpreted as indicating that the non-Chinese races in the south-west have come to their present seats by migration from Central China in remote antiquity. During the reign of a certain king a catastrophe reminding one of the biblical deluge threatened the Chinese world. The emperor held his minister of works, Kun, responsible for this misfortune, probably an inundation of the Yellow river such as has been witnessed by the present generation. Its horrors are described with poetical exaggeration in the Shu-k'ing. When the efforts to stop the floods had proved futile for nine years, Yau wished to abdicate, and he selected a virtuous young man of the name of Shun as his successor. Shun, a hereditary claimant to the throne, had been esteemed by the people so much that he could not have been made to take his place. Since Kun had not succeeded in stopping the floods, he was dismissed and his son Yü was appointed in his stead. Probably the waters began to subside of their own accord, Yü has been praised as the national hero about whom more than human powers. He is supposed to have cut canals through the hills, in order to furnish outlets to the floods, and to have performed feats of engineering compared to which, according to Von Richthofen, the construction of the St Gotthard tunnel without blasting materials would be child's play, and all within a few years.

The Hia Dynasty.—As a reward for his services Yü was selected to succeed Shun as emperor. He divided the empire into nine provinces, the description of which in the Yü-k'ung chapter of the "Canon of History" bears a suspicious resemblance to later accounts. Yü's reign has been assigned to the years 2205-2190, and the Hia dynasty, which had been made to extend to the overthrow in 1766 B.C. of Kié, its eighteenth and last emperor, a cruel tyrant of the most vicious and contemptible character. Among the Hia emperors we find Ch'ung-k'ung (2159–2147), whose reign has attracted the attention of European scholars by the mention of an eclipse of the sun, which his court astronomers had failed to predict. European astronomers and sinologists have brought much acumen to bear on the problem involved in the Shu-k'ing account in trying to decide which of the several eclipses known to have occurred about that time was identical with the one observed in China under Ch'ung-k'ung.

The Shang, or Yin, Dynasty.—This period, which preceded the classical Chou dynasty, is made to extend from 1766 to 1122 B.C. We must now be prepared to see an energetic or virtuous ruler at the head of a dynasty and either a cruel tyrant or a contemptible weakling at the end of it. It seems natural that this should be so, but Chinese historians, like the writers of Roman history, have a tendency to exaggerate both good and bad qualities. Ch'êng-tang, its first sovereign, is represented as a model of goodness and of humane feeling towards his subjects. Even the animal world benefited by his kindness, inasmuch as he abolished all useless torture in the chase. His great minister I Yin, who had greatly assisted him in securing the throne, served two of his successors. P'an-k'ung (1401) and Wu-ting (1324) are described as good rulers among a somewhat indifferent set of monarchs. The Shang dynasty, like the Hia, came to an end through the reckless vice and cruelty of a tyrant (Chou-sin with his consort Ta-ki). China had even in those days to maintain her position as a civilized nation by keeping at bay the barbarous nations by which she was surrounded. Chief among these were the ancestors of the Hsiung-
HISTORY] CHINA 193

tribes, or Huns, on the northern and western boundaries. To fight them, to make pacts and compromises with them, and to befriend them with gifts so as to keep them out of the Imperial territories, had been the rôle of a palatine on the western frontier, the duchy of Chou, while the court of China with its vicious emperor gave itself up to effeminate luxury. Chou's evil practices had aroused the indignation of the palatine, subsequently known as Woen-wang, who in vain remonstrated with the emperor's criminal treatment of his subjects. The strength and integrity of Woen-wang's character had made him the corner-stone of that important epoch; and his name is one of the best known both in history and in literature. The courage with which he spoke his mind in rebuking his unworthy liege lord caused the emperor to imprison him, his great popularity alone saving his life. During his incarceration, extending over three years, he compiled the I-king; or "Canon of Changes," supposed to be the oldest book of Chinese literature, and certainly the most extensively studied by the nation. Woen-wang's son, known as Wu-wang, was destined to avenge his father and the many victims of Chou's cruelty. Under his leadership the people rose against the emperor and, with the assistance of his allies, "men of the west," possibly ancestors of the Huns, overthrew the Shang dynasty after a decisive battle, whereupon Chou's court committed suicide by setting fire to its palace.

Chou Dynasty.—Wu-wang, the first emperor of the new dynasty, named after his duchy of Chou on the western frontier, was greatly assisted in consolidating its empire by his brother, Chou-kung, i.e. "Duke of Chou." As the loyal prime-minister of Wu-wang and his successor the duchy of Chou laid the foundation of the government institutions of the dynasty, which became the prototype of most of the characteristic features in Chinese political and social life down to recent times. The brothers and adherents of the new sovereign were rewarded with fiefs which in the sequel grew into as many states. China thus developed into a confederation, resembling that of the German empire, inasmuch as a number of independent states, each having its own sovereign, were united under one liege lord, the emperor, styled "The Son of Heaven," who as high priest of the nation reigned in the name of Heaven. The emperor represented the nation in sacrificing and praying to God. His relations with his vassals and government officials, and those of the heads of the vassal states with their subjects as well as of the people among themselves were regulated by the most rigid ceremonial. The dress to be worn, the speeches to be made, and the postures to be assumed on all possible occasions, whether at court or in private life, were subject to regulations. The duke of Chou, or whoever may have been the creator of this system, showed deep wisdom in his speculations, if he based that immutability of government which in the sequel became a Chinese characteristic, on the physical and moral immutability of individuals by depriving them of all spontaneous action in public and private life. Originally and nominally the emperor's power as the ruler over his vassals, who again ruled in his name, was unquestionable; and the first few generations of the dynasty saw no decline of the original strength of central power. A certain loyalty based on the traditional ancestral worship counteracted the desire to revolt. The rightful heir to the throne was responsible to his ancestors as his subjects were to theirs. "We have to do as our ancestors did," the people argued; "and since they obeyed the ancestors of our present sovereign, we have to be loyal to him." Interference with this time-honoured belief would have amounted to a rupture, as it were, in the nation's religious relations, and as long as the people looked upon the emperor as the Son of Heaven, his moral power would outweigh strong armies sent against him in rebellion. The time came soon enough when central power depended merely on this spontaneous loyalty.

Not all the successors of Wu-wang profited by the lessons given them by past history. Incapacity, excessive severity and undue weakness had created discontent and loosened the relations between the emperor and his vassals. Increase in the extent of the empire greatly added to this decline of central power. For the emperor's own dominion was centrally situated and surrounded by the several confederate states; its geographical position prevented it from participating in the general aggrandisement of China, and increase in territory, population and prestige had become the privilege of boundary states. Tatar tribes in the north and west and the aboriginal Man barbarians in the south were forced by warfare to yield land, or enticed to exchange it for goods, or induced to mingle with their Chinese neighbours, thus producing a mixed population combining the superior intelligence of the Chinese race with the energetic and warlike spirit of barbarians. These may be the main reasons which gradually undermined the Imperial authority and brought some of the confederate states to the front, so as to overshadow the authority of the Son of Heaven himself, whose military and financial resources were inferior to those of several of his vassals. A few out of the thirty-five sovereigns of the Chou dynasty were distinguished by extraordinary qualities. Mu-wang of the 8th century performed journeys far beyond his western frontier of his empire, and was successful in warfare against the Dog Barbarians, described as the ancestors of the Hsiung-nu, or Huns. The reign of Siian-wang (787-782 B.C.) was filled with warfare against the Tungtans and the Huns, called Hiien-yuen in a contemporary poem of the "Book of Odes"; but the most noteworthy reign in this century is that of the luscious Yu-wang, the oppressiveness of whose government had caused a hard represented in the "Book of Odes" to complain about the emperor's evil ways. The writer of this poem refers to certain signs showing that Heaven itself is indignant at Yu-wang's crimes. One of these signs was an eclipse of the sun which had recently occurred, the date and month being clearly stated. This date corresponds exactly with August 29, 776 B.C.; and astronomers have calculated that on that precise date an eclipse of the sun was visible in North China. This, of course, cannot be a mere accident; and since the date falls into the sixth year of Yu-wang's reign, the coincidence is bound to increase our confidence in that part of Chinese history. Our knowledge of it, however, is due to mere chance; for the record of the eclipse would probably not have been preserved until our days had it not been interpreted as a kind of ttekul upharsin owing to the peculiarity of the political situation. It does not follow, therefore, as some foreign critics assume, that the historical period begins as late as Yu-wang's reign. China has no architectural witnesses to testify to its antiquity as Egypt has in its pyramids and temple ruins; but the sacrificial bronze vessels of the Shang and Chou dynasties, with their characteristic ornaments and hieroglyphic inscriptions, seem to support the historical tradition inasmuch as natural development may be traced by the analysis of their artistic and palaeographic phases. Counterfeits, say a thousand years later, could not have resisted the temptation to introduce patterns and hieroglyphic shapes of later periods; and whatever bronzes have been assigned to the Shang dynasty, i.e some time in the second millennium B.C., exhibit the Shang characteristics. The words occurring in their inscriptions, carefully collected, may be shown to be confined to ideas peculiar to primitive states of cultural life, not one of them pointing to an invention we may suspect to be of later origin. But, apart from this, it seems a matter of individual judgment how far back beyond that indisposable year 776 B.C. a student will date the beginning of real history.

In the 7th century central authority had declined to such an extent that the emperor was merely the nominal head of the confederation, the hegemony in the empire falling in turn to one of the five principal states, for which reason the Chinese speak of a period of the "Five Leaders." The state of Ts'i, corresponding to North Shan-tung, had begun to overshadow the other states by unprecedented success in economic enterprise, due to the prudent advice of its prime minister, the philosopher Kuan-tse. Other states attained leadership by success in warfare. Among these leaders we see duke Mu of T'sin (659 B.C.), a state on the western boundary which was so much influenced by amalgamation with its Hunic neighbours that the purely Chinese states regarded it as a barbarian country. The emperor was in those days a mere shadow; several of his vassals had
Having settled the internal affairs of his kingdom, he turned his attention to the enemies beyond his frontier. Chief among these were the Hiung-nu Tatars, whose attacks had for years disquieted the Chinese and neighbouring principalities. Against these foes he marched with an army of 300,000 men, exterminating those in the frontiers of China, and driving the rest into Mongolia. On his return from this campaign he was called upon to face a formidable rebellion in Ho-nan, which had been set on foot by the adherents of the feudal princes whom he had extinguished. He dispersed the rebel leaders of those provinces and subdued the tribes on the south of the Nan-shan ranges, i.e., the inhabitants of the modern provinces of Pu-kien, Kwang-tung and Kwang-si. The limits of his empire were thus as nearly as possible those of modern China proper, and with the military energy of the age he was able to effect this remarkable change. Finding that the northern states of T'ai, Chao and Yen were building lines of fortification along their northern frontier for protection against the Hiung-nu, he conceived the idea of building one gigantic wall, which would be a bar to the progress of the enemy. The idea of constructing a wall from the sea to the farthest western corner of the modern province of Kan-suh. This work was begun under his immediate supervision in 214 B.C. His reforming zeal made him a popular leader with the upper classes. Schoolmen and pedants held up to the admiration of the people the heroes of the feudal times and the advantages of the system they administered. Seeing in this propaganda danger to the state Shi Hwang-ti determined to break once and for all with the past. To this end he proceeded with the destruction of the books. Having finally decided in council to the past history of the empire, and many scholars were put to death for failing in obedience to it. (See infra § Chinese Literature, §§ History.) The measure was unpopular and on his death (210 B.C.) reformers and the rest were not spared. His son Tze-yung surrendered to Liu Pang, the prince of Han, one of the two generals who were the leaders of the rebellion. He afterwards fell into the hands of Hiung Yu, the other leader, who put him, and his family and associates to death. Hiung Yu aspiring to imperial honours, war broke out between him and Liu Pang. After five years’ conflict Hiung Yu was killed in a decisive battle before Wu-hiang. Liu Pang was then proclaimed emperor (206 B.C.) under the title of Kao-ti, and the new line was styled the Han dynasty.

Kao-ti established his capital at Lo-yang in Ho-nan, and afterwards removed it to Chang-an in Shen-si. Having found his right to rebel on the oppressive nature of the laws promulgated by Shi Hwang-ti, he abolished the ordinances of Tsin, except that referring to the destruction of the books—for, like his great predecessor, he dreaded the influence exercised by the literati—and he exchanged the worship of the gods of the soil of Tsin for that of those of Han, his native state. His successor Hwei-ti (194-184 B.C.), however, gave every encouragement to literature, and appointed a commission to restore as far as possible the texts which had been destroyed by Shi Hwang-ti. In this the commission was very successful. It was discovered that in many cases the law had been evaded, while in numerous instances scholars were found to write down from memory the text of books of which all copies had been destroyed, though in some cases the purity of the text is doubtful and in other cases there were undoubted forgeries. A period of repose was now enjoyed by the empire. There was peace within its borders, and its frontiers remained unchallenged, except by the Hiung-nu, who suffered many severe defeats. Thwarted in their attacks on China, these marauders attacked the kingdom of the Yueh-chi, which had grown up in the western extremity of Kan-suh, and after much fighting drove their victims along the T'ien-shan-nan-lu to the territory between Turkestan and the Caspian Sea. This position of affairs suggested to the emperor the idea of forming an offensive and defensive line from the Yueh-chi against the Hiung-nu. With this object the general Chang K’ien was sent as an ambassador to western Tartary. After having been twice imprisoned by the Hiung-nu he returned to China. Chang K’ien had actually reached the court of the Yueh-chi, or Indo-Scythians as they were called owing to their having become masters of India later on, and paid a visit to the kingdom of Bactria, recently conquered by the Yueh-chi. His report on the several kingdoms of western Asia opened up a new world to the Chinese, and numerous elements of culture, plants and animals were then imported for the first time from the west into China. While in Bactria Chang K’ien’s attention was first drawn to the existence of India, and attempts to send expeditions,
though at first fruitless, finally led to its discovery. Under Wu-ti (140-86 B.C.) the power of the Hiung-nu was broken and eastern Turkestan changed into a slave colony, through which caravans could safely pass to bring back merchandise and art treasures from Persia and the Roman market. By the Hans the feudal system was restored in a modified form; 105 feudal principalities were created, but they were more or less under the jurisdiction of civil governors appointed to administer the thirteen chows (provinces) into which the country was divided.

About the beginning of the Christian era Wang Mang rose in revolt against the infant successor of P'ing-ti (A.D. 1), and in A.D. 9 proclaimed himself emperor. He, however, only gained the suffrages of a portion of the nation, and before long his oppressive acts estranged his supporters. In A.D. 23 Liu Siu, one of the princes of Han, completely defeated him. His head was cut off, and his body was torn in pieces by his own soldiery.

Liu Siu, was proclaimed emperor under the title of Kwang-wu-ti, reigned from A.D. 58 to 76. Having fixed on Lo-yang in Ho-nan as his capital, the line of which he was the first emperor became known as the Eastern Han dynasty. He was the founder of a new dynasty, and it is, perhaps, a just comparison to say that he was the first emperor of that Dynasty.

During the reign of his successor Ming-ti, A.D. 65, Buddhism was introduced from India into China (see ante § Religion). About the same time the celebrated general Pan Ch’ao was sent on an embassy to the king of Shen-shen, a small state of Turkestan, near the modern Pidjan. Before long he added the states of Shen-shen, Khotan, Kucha and Kashgar as appanages to the Chinese crown, and for a considerable period the country enjoyed prosperity. The Han dynasty (in the term the Eastern Han dynasty) has been considered the first national dynasty and is one of the most famous in China; nor has any ruling family been more popular. The Chinese, especially the northern Chinese, still call themselves "the sons of Han." The wealth and trade as well as the culture of the country was greatly developed, and the competitive examinations for literary degrees instituted. The homogeneity of the nation was so firmly established that subsequent dissensions and conquests could not alter fundamentally the character of the nation.

Towards the end of the 2nd century the power of the Eastern Hans declined. In 173 a virulent pestilence, which continued for eleven years, broke out. A magical cure for this plague was said to have been discovered, and the first prince of the 20th century, Wang Chang, a single month won a sufficiently large following to enable him to gain possession of the northern provinces of the empire. He was, however, defeated by Ts*aou Ts’ou, another aspirant to imperial honours, who chose the name of Hieh-tung. Hieh-tung proclaimed himself emperor, adopting the title of Wei as the appellation of his dynasty. There were then, however, two other claimants to the throne, Liu Pei and Sun Ch’i-tan, and the three adventurers agreed to divide the empire among them. Ts’ou Pei, under the title of Wen-ti, ruled over the kingdom of Wei (220), which occupied the whole of the central and northern portion of China. Liu Pei established the Shuh Han dynasty in the modern province of Sze-ch’ien (221), and called himself Chiao-lo, and to Sun Ch’i-tan fell the southern provinces of the empire, from the Yangtsze-kiang southwards, including the modern Tongking, which he formed into the kingdom of Wu with Nan-king for his capital, adopting for himself the imperial style of Ta-ti (A.D. 222-266).

China during the period of the "Three Kingdoms" was a house divided against itself. Liu Pei, as a descendant of the house of Han, looked upon himself as the rightful sovereign of the empire, and was supported and recognized by the Ch’iu-kuo Liang to support his claims. This army was met by an opposing force under the Wei commander Sze-ma I, of whom Chinese historians say that 'he led armies like a god,' and that by action and ability he was everything that the name of Ch’in implied. But the close of this campaign brought no peace to the country. Wars became chronic, and the reins of power slipped out of the hands of emperors into those of their generals. Foremost among these was Sze-ma Chao, who, after the death of his own family, alone of the Wu princes I left a son, Sze-ma Chao, scarcely less distinguished than himself, and when Sze-ma Chao died his honours descended to Sze-ma Yen, who deposed the ruling sovereign of Wei, and proclaimed himself emperor (A.D. 265). His dynasty he styled the Western Tsin dynasty, and he adopted for himself the title of Wu-ti. The most notable event in this reign was the advent of the ambassadors of the emperor Diocletian in 284. For some years the neighbouring states appear to have transferred their allegiance from the house of Wei to that of Ts’in. Wu-ti's successors proving, however, weak and incapable, the country soon fell again into disorder. The Hiung-nu renewed incursions into the empire at the beginning of the 4th century, and in the confusion which followed, an adventurer named Ta-ti (or Tung) Yuen established himself, and was raised to the throne at Ping-yang in Shan-shi and afterwards in Lo-yang and Chang-an. The history of this period is very chaotic. Numerous states sprang into existence, some founded by the Hiung-nu, others by the same Ta-ti Yuen. The Hiung-nu was finally divided into two parts, the north and the south. In the north four families reigned successively, two of which were of Sien-fo origin, viz. the Wei and the How Chow, the other two, the Pi T’si and the How Liang, being Chinese. In the south five different houses supplied rulers, which were all of Chinese descent.

This period of disorder was brought to a close by the establishment of the Suy dynasty (590). Among the officials of the ephemeral dynasty of Chow was one Yang Kien, who, on his daughter becoming empress (579) was created duke of Lo-yang. Two years later Yang Kien proclaimed himself emperor. The country, weary of contention, was glad to acknowledge his undisputed authority; and during the sixteen years of his reign the internal affairs of China were comparatively peacefully administered. The emperor instituted an improved code of laws, and added 5,000 volumes to the 10,000 which composed the imperial library. Abroad, his policy was equally successful. He defeated the Tatars and chased them into the Korean Peninsula. In 578 the Chinese claimed the diocese of Sien-pi (Hiung-han) and put himself at the head of an expedition against the Uighurs, while one of his generals annexed the Lu-chu Islands to the imperial crown. During his reign the volumes in the imperial library were increased to 54,000, and in the next year he himself spent 10,000 catties in training as a soldier. He continued the construction of the walls, and in constructing unprofitable canals. These and other extravagances caused the emperor to use the utmost economy, as a result of which discontent began to develop. He failed to continue the emperor’s reform of the calendar. In 592 he made an expedition to the We-Tatars and decreed the conversion of the tribes to Buddhism; and giving a favourable reception to an embassy from Mahommed (see ante § Religion). On the accession of Kao-tung (650) his wife, Wu How, gained supreme influence, and on the death of her husband in 683 she set aside his lawful successor, Chung-tsung, and took possession of the throne. This was the first occasion the country was ruled by a dowager empress. She governed with discretion, and her armies defeated the Khitan in the north-east and also the Tibetans, who had latterly gained possession of Kucha, Khotan and Kashgar. On her death, in 705, Chung-tsung partially cleared the obstructions which he had lived during his mother’s reign. But his wife, desiring to play a similar role to that enjoyed by her mother-in-law, poisoned him and set his son, Ju-tung (710), on the throne. This monarch, who was weak and vicious, was succeeded by Yuen-tung (713), who introduced reform into the administration and encouraged literature and learning. The king of Khoikand applied for aid against the Tibetans and Arabs, and Yuen-tung
sent an army to his succour, but his general was completely defeated. During the disorder which arose in consequence of the invasion of the northern provinces by the Khitans, General An Lu-shan of the T’ang, who had himself placed himself at the head of a revolt, and having secured Tung-kwan on the Yellow river, advanced on Chang-an. Thereupon the emperor fled, and placed his son, Su-tsung (756-762), on the throne. This sovereign, with the help of the forces of Khotan, Khokand and Bokhara, of the Uighurs and of some 4000 Arabs sent by the caliph Mansur, completely defeated An Lu-shan. During the following reigns the Tibetans made constant incursions into the western provinces of the empire, and T’ai-tsung (763-80) purchased the assistance of the Turks against those intruders by giving a Chinese princess as wife to the khan.

At this epoch the eunuchs of the palace gained an unwonted degree of power, and several of the subsequent emperors fell victims to their plots. The T’ang dynasty, which for over a hundred years had governed firmly and for the good of the nation, began to decline. The history of the 8th and 9th centuries is for the most part a monotonous record of feeble governments, oppressions and rebellions. Almost the only event worth chronicling is the iconoclastic policy of the emperor Wu-tsun (841-847), which their religious zeal and the increase of monasteries and ecclesiastical establishments as an evil, he abolished all temples, closed the monasteries and nunneries, and sent the inmates back to their families. Foreign priests were subjected to the same repressive legislation. The Mohammedans were likewise driven from the empire, and whenever they came. Buddhism again revived during the reign of the emperor T’ai-tsun (860-874), who, having discovered a bone of Buddha, brought it to the capital in great state. By internal dissensions the dynasty had become so weakened that, when the presence of the Chinese was found no difficulty in gaining possession of the throne (907). He took the title of T’ai-tsun, being the first emperor of the Later T’ang dynasty. Thus ended the T’ang dynasty, which is regarded as being the last in Chinese literature.

Five dynasties, viz. the Later Liang, the Later T’ang, the Later T’ien, the Later Han and the Later Chow, followed each other between the years 907 and 960. Though the monarchs of these lines nominally held the throne, the country was so stricken by the wars that their power was confined to very narrow limits. The disorders which were rife during the time when the T’ang dynasty was tottering to its fall fostered the development of independent states, and so arose Liang in Ho-nan and Shan-tung, Ki in Shen-si, Ch’un-ch’i in Hansh’an, Chou in Shu-ch’un and parts of Kwei-yew, K’ai-feng in K’ai-feng, Ho-nan, and Shan-tung, and Ho-nan in Kwang-tung and the Uighurs in Tangut.

A partial end was made to this recognized disorder when, in 960, General Chao Kw’ang-yin was proclaimed by the army emperor in succession to the youthful Kung-ti, who was compelled to abdicate. The circumstances of the time justified the change. It required a strong hand to weld the empire together again, and to resist the attacks of the Khi’tan Tatars, whose rule at this period extended over the whole of Manchuria and Liao-tung. Against these aggressive neighbours T’ai-tsun (né Chao Kw’ang-yin) directed his efforts with varying success, and he died in 976, while the war was still being waged. His son T’ai-tsun (976-997) entered on the campaign with energy, but in the end was compelled to conclude a peace with the Khi’tan. His successor, Ch’en-tsun (997-1022), paid them tribute to abstain from further incursions. Probably this tribute was not sent regularly; at all events, under Jén-tsun (1023-1064), the Khi’tan again threatened to invade the empire, and were only bought off by the promise of an annual tribute of 200,000 horses besides a great number of silks and other goods. Neither was this arrangement long binding, and so formidable were the advances made by the Tatars in the following reigns, that Hwei-tsun (1101-1112) invited the Nüchi Tatars to expel the Khi’tan from Liao-tung. This they did, but having once possessed themselves of the country they declined to yield it to the Chinese, and the result was that a still more aggressive neighbour was established on the north-eastern frontier of China. The Nüchi or Khi’tan, as they now styled themselves, overran the provinces of Chi-hi, Shen-si, Shan-si and Ho-nan, and during the reign of Kao-tsun (1127-115) they advanced their conquests to the line of the Yangtze-k’iang. From this time the Sung ruled only over southern China; while the Khi’tan or “Golden” dynasty reigned in the north. The Khi’tan made Chüng-tu, which occupied in part the site of the modern Peking, their usual residence. The Sung fixed their capital at Nan-k’ang and afterwards at Hang-chou.

Between them and the Khi’tan there was almost constant war. During this period the Mongols began to acquire power in eastern Asia, and about the beginning of the 13th century the forces of Jenghiz Khan (q.v.) invaded the north-western frontier of China and the principality of Hia, which at that time consisted of the modern provinces of Shen-si and Kan-suh. To purchase the good-will of the Mongols the king of Hia agreed to pay them a tribute, and gave a princess in marriage to their ruler. In consequence of a dispute with the Khidetan war, Jenghiz Khan determined to invade Liao-tung. He was aided by the followers of the Khi’tan leader Yeh-li Tsu-tsa’i, and in alliance with this general he captured Liao-yang, the capital city.

55 After an unsuccessful invasion of China in 1212, Jenghiz Khan renewed the attack in 1213. He divided his armies into four divisions, and, as China was divided over Ho-nan, Chi-hi and Shan-tung, destroying upwards of ninety cities. It was their boast that a horseman might ride without stumbling over the sites where those cities had stood. Panicky they would not be driven over.

After the effect of this Khi’tan army, much against the advice of his ministers, who foresaw the disastrous effect this retreat would have on the fortunes of Khi’tan. The state of Sung, which up to this time had paid tribute, now described Jenghiz Khan the khan of the Khidetan. In 1214, Khi’tan and Sung established the border along the Great wall, which, however, they were unable to defend. In 1227 Khi’tan Khan died.

With the view to the complete conquest of China by the Khidetan, Jenghiz declined to nominate either of the eldest two sons who had Jenghiz Khan’s traditional name. His succession was determined by his son Ogedai, whose mother was a Tarar. On hearing the death of Jenghiz Khan the Khi’tan sent an embassy to his successor desiring peace, but Ogedai told them there would be no peace for them until their first emperor should be captured. The effect of this Khi’tan, and without any code of laws. But the consolidation of the nation by the conquests of Jenghiz Khan made it necessary to establish a recognized code of laws, and one of the first acts of Ogedai was to commission the code of laws. After the death of Ogedai, the various custom-houses in Chi-hi, Shan-tung, Shan-si and Liao-tung, and for this purpose divided these provinces into ten departments. Meanwhile the war with the Khi’tan was carried on with energy. In 1222 Ogedai was captured by the Khi’tan. Two years later, Tü-lü, brother of Ogedai, took Őng-si and Han-chung Fu, in the flight from which last-named place 100,000 persons are said to have perished. Following the course of the river in Nanchow, Khi’tan was captured in 1221, and was nominally subdued by the Mongols, and fortresses, and defeated the army of Khi’tan at Mount Shan-féng.

In 1232 the Mongols made an alliance with the state of Sun, by which, on condition of Sung helping to destroy Khi’tan, the Khi’tan was to have the property of Sun for ever. The effect of this the Mongols without any code of laws. But the consolidation of the nation by the conquests of Jenghiz Khan made it necessary to establish a recognized code of laws, and one of the first acts of Ogedai was to commission the code of laws. After the death of Ogedai, the various custom-houses in Chi-hi, Shan-tung, Shan-si and Liao-tung, and for this purpose divided these provinces into ten departments. Meanwhile the war with the Khi’tan was carried on with energy. In 1222 Ogedai was captured by the Khi’tan. Two years later, Tü-lü, brother of Ogedai, took Őng-si and Han-chung Fu, in the flight from which last-named place 100,000 persons are said to have perished. Following the course of the river in Nanchow, Khi’tan was captured in 1221, and was nominally subdued by the Mongols, and fortresses, and defeated the army of Khi’tan at Mount Shan-féng.

The Mongol invasion of China during the 12th century. After the death of Ogedai, the various custom-houses in Chi-hi, Shan-tung, Shan-si and Liao-tung, and for this purpose divided these provinces into ten departments. Meanwhile the war with the Khi’tan was carried on with energy. In 1222 Ogedai was captured by the Khi’tan. cut short, and the nobles, disregarding the claims of Chellemen, proclaimed as emperor Mangu, the eldest son of Tu-tu. Under this monarch the war against Sung was carried on with energy, and Kublai, outstripping the bounds of Sung territory, made his way into the province of Yen-nan, at that time divided into a number of independent states, and having attached them to his brother's crown he passed on into Tibet, Tongking and Cochinchina, and thence striking northwards entered the province of Kwang-si.

On the death of Mangu in 1259 Kublai (q.r.) ascended the throne. Never in the history of China was the nation more illustrious, nor its power more widely felt, than under his sovereignty. During the first twenty years of his reign Sung kept up a resistance against his authority. Their last emperor Ping-ti, seeing his cause lost, drowned himself in the sea. The Sung dynasty, which had ruled southern China 320 years, despite its misfortunes, is accounted one of the great dynasties of China. During its sway arts and literature were cultivated and many eminent writers flourished. His enemies subdued, Kublai Khan in 1280 assumed complete jurisdiction as emperor of China. He took the title of Shih-su and founded what is known as the Yuen dynasty. Kublai's name, which in the Chinese language became known as Kaanbaligh (city of the khan), in medieval European chronicles, Cambaluc, and later as Peking. At this time his authority was acknowledged "from the Frozen Sea, almost to the Straits of Malacca. With the exception of Hindustan, Arabia and the westernmost parts of Asia, all the Mongol princes as far as the Dnieper declared themselves his vassals, and brought regularly their tribute." It was during this reign that Marco Polo visited China, and he describes in glowing colours the virtues and glories of the "great khan." His rule was characterized by discretion and munificence. He undertook public works, he patronized literature, and relieved the distress of the poor, but the Chinese never forgot that he was an alien and regarded him as a barbarian. He died unregretted in 1294. His son had died during his lifetime, and after some contention his grandson Timur ascended the throne under the title of Yuen-cheng. This monarch died in 1328 after an uneventful reign, and, as he left no son, Wusung, a Mongol prince, became emperor. To him succeeded Jen-tsung in 1322, who made himself conspicuous by the honour he showed to the memory of Kublai and to that of the sound policy pursued during the memory of Chinghiz Khan. The relations between Mongols and Chinese than had hitherto been done. This act of justice gave great satisfaction to the Chinese, and his death ended a peaceful and prosperous reign in 1326. At this time there appears to have been a considerable commercial intercourse between Europe and China. But after Jen-tsung's death the dynasty fell on evil days. The Mongols in adopting Chinese civilization had lost much of their martial spirit. They were still regarded as alien by the Chinese and numerous secret societies were formed to achieve their overthrow. Jen-tsung's successors were weak and incapable rulers, and in the person of Shun-ti (1333-1368) were summed up the vices and faults of his predecessors. Revolts broke out, and finally this descendant of Jenghiz Khan was compelled to fly before Chu Yen-chang, the son of a Chinese labouring man. Deserted by his followers, he sought refuge in Yung-chang Fu, and there the last of the Yuen dynasty died. These Mongol emperors, whatever their faults, had shown tolerance to Christian missionaries and Papal legates (see ante & The Medieval Cathays).

Chinghiz Khan's position, more especially as his first care on becoming possessed of a district was to suppress lawlessness and to establish a settled government. In 1355 he captured Nanking, and proclaimed himself duke of Wu, but carefully avoided adopting any of the insignia of royalty. Even when master of the empire, thirteen years later, he still professed to dislike the idea of assuming the imperial title. His scruples were overcome, and he declared himself emperor in 1368. He carried his arms into Tartary, where he subdued the last semblance of Mongol power in that direction, and then bent his steps towards Liao-tung. Here the Mongols defended themselves with the bravery of despair, but unavailingly, and the conquest of this province left Hung-wu, as the founder of the new or Ming ("Bright") dynasty styled himself, without a foe in the empire.

All intercourse with Europe seems now to have ceased until the Portuguese arrived in the 16th century, but Hung-wu cultivated friendly relations with the Mandarins and even received the mission of the missionary Matteo Ricci (q.r.) arrived at the Chinese court; and though at first the emperor was inclined to send him out of the country, his abilities gradually won him the esteem of the sovereign and his wife. Hung-wu, who remained the scientific adviser of the court until his death in 1606.

About this time the Manchu Tatars, goaded into war by the injustice they were constantly receiving at the hands of the Chinese, led an army into China (1616) and completely defeated the force which was sent against them. Three years later they gained possession of the province of Liao-tung. These disasters overwhelmed the emperor, and he died of a broken heart in 1620.

In the same year Ti'en-ming, the Manchu sovereign, having declared himself independent, moved the court to San-k'u, to the east of Mukden, which, five years later, he made his capital. In 1627 Tsung-chêng, the last emperor of the Ming dynasty, ascended the Chinese throne. In his reign English merchants first made their appearance at Canton. The empire was now torn by internal dissensions.
Rebel bands, enriched by plunder, and grown bold by success, began to assume the proportion of armies. Two rebels, Li Tse-ch'ëng and Shang K'ô-hi, decided to divide the empire between them. Li besieged K'ai-fêng Fu, the capital of Ho-nan, and so long and closely did he beleaguer it that in the consequent famine human flesh was regularly sold in the markets. At length an imperial force came to raise the siege, but fearful of meeting Li's army, they cut through the dykes of the Yellow River, "China's Sorrow," and flooded the whole country, including the city. The rebels escaped to the mountains, but upwards of 200,000 inhabitants perished in the flood, and the city became a heap of ruins (1642). From K'ai-fêng Fu Li marched against the other strongholds of Ho-nan and Shen-si, and was so completely successful that he determined to attack Peking. A treacherous eunuch opened the gates to him, on being informed of which the emperor committed suicide. When the news of this disaster reached the general-commanding on the frontier of Manchu Tartary, he, in an unguarded moment, concluded a peace with the Manchus, and invited them to dispossess Li Tse-ch'ëng. The Manchus entered China, and after defeating a rebel army sent against them, they marched towards Peking. On hearing of the approach of the invaders, Li Tse-ch'ëng, after having set fire to the imperial palace, evacuated the city, but was overtaken, and his force was completely routed.

The Chinese now wished the Manchus to retire, but, having taken possession of Peking, they proclaimed the ninth son of the T'ien-ming emperor of China under the title of Shun-chi, and adopted the name of Ta-ts'ing, or "Great Pure," for the dynasty (1644). Meanwhile the mandarins at Nanking had chosen an imperial prince to ascend the throne. At this most inopportune moment "a claimant" to the throne, in the person of a pretended son of the last emperor, appeared at court. While this contention prevailed inside Nanking the Tartars had already appeared at the walls. There was no need for them to use force. The gates of the city were open, and they took possession of the city without bloodshed. Following the conciliatory policy they had everywhere pursued, they confirmed the mandarins in their offices and granted a general amnesty to all who would lay down their arms. As the Tatars entered the city the emperor left it, and after wandering about for some days in great misery, he drowned himself in the Yangtsze-kiang. Thus ended the Ming dynasty, and the empire passed again under a foreign yoke. By the Mings, who partly revived the feudal system by making large territorial grants to members of the reigning house, China was divided into fifteen provinces; the existing division into eighteen provinces was made by the Manchus.

All accounts agree in stating that the Manchu conquerors are descendants of a branch of the family which gave the Kin dynasty to the north of China about a hundred years before Christ, and that the Chinese, who at that time were called T'ao, were converted to Buddhism by their king and his court. The founder of the Manchu dynasty is said to have been the fourth king of the Khitai Tartar, who was at this time the ruler of the western provinces from the Amur to the Yenesei. His name was Dow-kow, and he died in 1636. His son was chosen as emperor at K'hotan in 1637, and was called Manchu. The Manchu dynasty, which was founded in 1644, was to last for two hundred and thirty years.

Trade with Europe.

The British trade was then a monopoly of the East India Company. The trade, largely in opium, tea, and silk, was subject to many exceptions and restrictions, and many acts of gross injustice were committed on the persons of Englishmen. To obtain some redress the British government at length sent an embassy to Peking (1759) and Lord Macartney was chosen to head it. This embassy was received with every courtesy, as showing that Great Britain was a state tributary to China, and Lord Macartney was received with every courtesy. But the concessions he sought were not accorded, and in this sense his mission was a failure.

Kia-k'ing's reign was disturbed and disastrous. In the northern and western provinces, rebellion after rebellion broke out, due in a great measure to the carelessness, incompetency and obstinacy of the emperor, and the coasts were infested with pirates, whose number and organization enabled them for a long time to hold the imperial fleet in check. Meanwhile the condition of the foreign merchants at Canton had not improved, and to set matters on a better footing the British government despatched a second ambassador in the person of Lord Amherst to Peking in 1816. As he declined to kowtow before the emperor, he was not admitted to the imperial presence and the mission proved See Morse's Trade and Administration of the Chinese Empire, chap. ix.
CHINA

The new emperor, though possessed in his early years of considerable energy, had no sooner ascended the throne than he gave himself up to the pursuit of pleasure. The reforms which his first manifestations forebode seriously occupied his attention. Insurrection occurred in Formosa, Kwang-si, Ho-nan and other parts of the empire, and the Triad Society, which had originated during the reign of K'ang-hi, again became formidable.

More important to the future of the country than the internal disturbances was the new attitude taken at this time towards China by the nations of Europe. Hitherto the European missionaries and traders in China had been dependent upon the goodwill of the Chinese. The Portuguese had been allowed to settle at Macao (q.v.) for some centuries; Roman Catholic missionaries since the time of Ricci had been alternately patronized and persecuted; and, after the Europeans allowed to trade at Canton continued to suffer under vexatious regulations—the Chinese in general regarded Europeans as barbarians, “foreign devils.” Of the armed strength of Europe they were ignorant. They were now to be undeceived. Great Britain being the first power to take action. The hardships inflicted on the British merchants at Canton became so unbearable that when, in 1834, the monopoly of the East India Company ceased, the British government sent Lord Napier as minister to superintend the foreign trade at that port. Lord Napier was inadequately supported, and the anxieties of his position brought on an attack of fever, from which he died at Macao after a few months’ residence in China. The chief cause of complaint adduced by the mandarins was the introduction of opium by the merchants, and for years they attempted by every means in their power to put a stop to its importation. At length Captain (afterwards Admiral Sir Charles) Elliot, the Superintendent of trade, in 1839 agreed that all the opium in the hands of the Englishmen should be given up to the native authorities, and he exacted a pledge from the merchants that they would no longer deal in the drug. On the 3rd of April 20,283 chests of opium were handed over to the mandarins and were by them destroyed. The surrender of the opium led to further demands by Lin Tze-su, the Chinese imperial commissioner, demands which were considered by the British government to amount to a casus belli, and in 1840 war was declared. In the same year the fleet captured Chusan, and in the following year the Bogue Forts fell, in consequence of which operations the Chinese agreed to cede Hong-Kong to the victors and to pay them an indemnity of 6,000,000 dollars. As soon as this news reached Peking, K’i Shen, who had succeeded Commissioner Lin, was dismissed from his post and degraded, and Yi Shen, an old Tatar, was appointed in his room. Before the new commissioner reached his post Canton had fallen into the hands of Sir Hugh Gough, who, shortly afterwards Amoy, Ning-po, Tsin-hai in Chusan, Chapa, Shanghai and Chin-kiang Fu shared the same fate. Nanking would also have been captured had not the imperial government, dreading the loss of the “Southern Capital,” proposed terms of peace. Sir Henry Pottinger, who had succeeded Captain Elliot, concluded, in 1842, a treaty with the imperial commissioners, by which the four additional ports of Amoy, Fu-chow, Ningpo and Shanghai were declared open to foreign trade, and an indemnity of 21,000,000 dollars was to be paid to the British.

On the accession of Hien-feng in 1850, a demand was raised for the reforms which had been hoped for under T’ai-kwang, but Hien-feng possessed in an exaggerated form the selfish and tyrannical nature of his father, together with a voluptuary’s craving for every kind of sensual pleasure. For some time Kwang-si had been in a very disturbed state, and when the people found that there was no hope of relief from the oppression they endured, they proclaimed a youth, who was said to be the representative of the last emperor of the Ming dynasty, as emperor, under the title of T’ien-tê or “Heavenly Virtue.” From Kwang-si the revolt spread into Hu-peh and Hu-nan, and then languished from lack of troops and want of organization. The political condition of the empire appeared to be a possibility that, by force of arms and the persuasive influence of money, the imperialists would re-establish their supremacy, a leader presented himself in Kwang-si, whose energy of organization and determination proved a success. He possessed the same greatness of soul, asceticism, and spirit of religiosity as his predecessors, and his success appeared to be a possibility that, by force of arms and the persuasive influence of money, the imperialists would re-establish their supremacy, a leader presented himself in Kwang-si, whose energy of organization and determination proved a success. CHINA

With the measure of peace which was then restored to the country trade rapidly revived, except in Yunn-nan, where the Mahommedan rebels, known as Panthays, under Suleiman, still kept the imperial forces at bay. Against these foes the government was careless to take active measures, until in 1872 Prince Kung, the eunuch of the new emperor, Bao-chi, set out to punish them. The expedition, however, was defeated and Prince Kung was temporarily deprived of his office.

The accession of Bao-chi, who had succeeded to the throne at the age of 18, was announced in 1873. In 1874 the two deputy empresses resigned their powers as regents. This long-expectation was seized upon by the foreign ministers, who forced the young emperor to choose his ministers. The ministers soon began to interfere with the administration, and the government was greatly embarrassed. The death of the empress consort in 1875 was followed by a similar ill fortune. The empress dowager had died in 1874, and the empress dowager Fu had been removed from office by her brother-in-law, Prince Kung, the regent, who was succeeded in 1875 by his son, the prince regent Bao-chi.

The two deputy empresses—"the Empress Tsz’e An, principal wife of the emperor T’ung-chi, Hien-feng, and the Empress Tsz’e Hsi, secondary wife of the same emperor, and mother of the emperor T’ung-chi. Yet there were circumstances connected with the accession of the emperor K’ang-hi, who had himself succumbed to an ominous brief and mysterious illness, left a young widow in an advanced state of pregnancy, and she had given birth to a male child her son would have been the rightful heir to the throne. But even before she sickened and died—of grief, it was officially stated, at the loss of her imperial spouse—the dowager-empresses had solved the question of the succession by placing K’ang-su on the throne, a measure which was not only in itself arbitrary, but also in direct conflict with one of the most sacred of Chinese traditions. The solemn rites of ancestor-worship, incumbent on every Chinaman, and, above all, upon the emperor, can only be properly performed by a member of a younger generation than those whom it is his duty to honour. The emperor K’ang-su, being a first cousin to the emperor T‘ung-chi, was not therefore qualified to offer up the customary sacrifices before the ancestral tablets of his predecessor. The accession of an infant in the place of T‘ung-chi achieved, however, for the time being what was doubtless the paramount object of the policy of the two empresses, namely, their undisturbed tenure of the regency, in which the junior empress Tsz’e Hsi, a woman of unquestionable ability and boundless ambition, had gradually become the predominant partner.

The first question that occupied the attention of the government under the new reign was one of the gravest importance, and nearly led to a war with Great Britain. The Indian government was in dispute about the old trade relations between Burma and the south-west provinces, which had been interrupted by the Yunn-nan rebellion, re-established, and for that purpose proposed to send a mission across the frontier into China. The Peking government assented and issued passports for the party, which was under the command of Colonel Browne. Mr A. R. Margary, a young and promising member of the Indian consular service, who was told off to accompany the expedition as interpreter, was treacherously murdered by Chinese at the small town of Manwyne and almost simultaneously an attack was made on the expedition by armed forces wearing Chinese uniform (January 1879). Colonel Browne with difficulty made his way back to Bhamo and the expedition was abandoned.

Tendentious negotiations followed, and, more than eighteen months after the outrage, an arrangement was come to on the basis of guarantees for the future, rather than vengeance for the past. The arrangement was embodied in the Chifu convention, dated 13th September 1876. The terms of the settlement comprised (1) a mission of apology from China to the British court; (2) the promulgation throughout the length and breadth of the empire of an imperial proclamation, setting out the right of foreigners to travel under passport, and the obligation of the authorities to protect them; and (3) the payment of indemnity. Additional articles were subsequently signed in London relative to the collection of ikkin on Indian opium and other matters.

Simultaneously with the outbreak of the Mahommedan rebellion in Yunn-nan, a similar disturbance had arisen in the north-west provinces of Shen-si and Kan-su. This was followed by a revolt of the whole of the Central Asian tribes, which for two thousand years had more or less acknowledged the imperial sway. In Kashgaria a nomad chief named Yakub Neg Khazad, having made himself amir, and seemed likely to establish a strong rule. The fertile province of Kulja or II, lying to the north of the "Tsanz" river, was taken possession of by Russia in 1876, and an arrangement was made with the prevailing anarchy, but with a promise that when China should have succeeded in re-establishing order in her Central Asian dominions it should be given back. The interest which was taken in the rebellion in Central Asia by the European powers, notably by the sultan of Turkey and the British government, aroused the Chung-chi to renewed efforts to recover their lost territories, and, as in the case of the similar crisis in Yunn-nan, they undertook the task with sturdy deliberation. They borrowed money for the expenses of the expedition, this being the first appearance of China as a borrower in the foreign markets, and appointed the viceroys, Tso Tsung-t’ang, commander-in-chief. By degrees the emperor’s authority was established from the confines of Kan-su to Kashgar and Yarkand, and Chinese garrisons were stationed in touch with the Russian outpost in the region of the Pamins. 

**Imperial family organisation and rank.**

The two deputy empresses—"the Empress Tsz’e An, principal wife of the emperor T‘ung-chi, Hien-feng, and the Empress Tsz’e Hsi, secondary wife of the same emperor, and mother of the emperor T‘ung-chi. Yet there were circumstances connected with the accession of the emperor K‘ang-hi, who had himself succumbed to an ominous brief and mysterious illness, left a young widow in an advanced state of pregnancy, and she had given birth to a male child her son would have been the rightful heir to the throne. But even before she sickened and died—of grief, it was officially stated, at the loss of her imperial spouse—the dowager-empresses had solved the question of the succession by placing K‘ang-su on the throne, a measure which was not only in itself arbitrary, but also in direct conflict with one of the most sacred of Chinese traditions. The solemn rites of ancestor-worship, incumbent on every Chinaman, and, above all, upon the emperor, can only be properly performed by a member of a younger generation than those whom it is his duty to honour. The emperor K‘ang-su, being a first cousin to the emperor T‘ung-chi, was not therefore qualified to offer up the customary sacrifices before the ancestral tablets of his predecessor. The accession of an infant in the place of T‘ung-chi achieved, however, for the time being what was doubtless the paramount object of the policy of the two empresses, namely, their undisturbed tenure of the regency, in which the junior empress Tsz’e Hsi, a woman of unquestionable ability and boundless ambition, had gradually become the predominant partner.

The first question that occupied the attention of the government under the new reign was one of the gravest importance, and nearly led to a war with Great Britain. The Indian government was in dispute about the old trade relations between Burma and the south-west provinces, which had been interrupted by the Yunn-nan rebellion, re-established, and for that purpose proposed to send a mission across the frontier into China. The Peking government assented and issued passports for the party, which was under the command of Colonel Browne. Mr A. R. Margary, a young and promising member of the Indian consular service, who was told off to accompany the expedition as interpreter, was treacherously murdered by Chinese at the small town of Manwyne and almost simultaneously an attack was made on the expedition by armed forces wearing Chinese uniform (January 1879). Colonel Browne with difficulty made his way back to Bhamo and the expedition was abandoned.

Tendentious negotiations followed, and, more than eighteen months after the outrage, an arrangement was come to on the basis of guarantees for the future, rather than vengeance for the past. The arrangement was embodied in the Chifu convention, dated 13th September 1876. The terms of the settlement comprised (1) a mission of apology from China to the British court; (2) the promulgation throughout the length and breadth of the empire of an imperial proclamation, setting out the right of foreigners to travel under passport, and the obligation of the authorities to protect them; and (3) the payment of indemnity. Additional articles were subsequently signed in London relative to the collection of ikkin on Indian opium and other matters.

Simultaneously with the outbreak of the Mahommedan rebellion in Yunn-nan, a similar disturbance had arisen in the north-west provinces of Shen-si and Kan-su. This was followed by a revolt of the whole of the Central Asian tribes, which for two thousand years had more or less acknowledged the imperial sway. In Kashgaria a nomad chief named Yakub Neg Khazad, having made himself amir, and seemed likely to establish a strong rule. The fertile province of Kulja or II, lying to the north of the "Tsanz" river, was taken possession of by Russia in 1876, and an arrangement was made with the prevailing anarchy, but with a promise that when China should have succeeded in re-establishing order in her Central Asian dominions it should be given back. The interest which was taken in the rebellion in Central Asia by the European powers, notably by the sultan of Turkey and the British government, aroused the Chung-chi to renewed efforts to recover their lost territories, and, as in the case of the similar crisis in Yunn-nan, they undertook the task with sturdy deliberation. They borrowed money—£1,600,000—for the expenses of the expedition, this being the first appearance of China as a borrower in the foreign markets, and appointed the viceroys, Tso Tsung-t’ang, commander-in-chief. By degrees the emperor’s authority was established from the confines of Kan-su to Kashgar and Yarkand, and Chinese garrisons were stationed in touch with the Russian outpost in the region of the Pamins.
CHINA

(December 1877). Russia was now called upon to restore Kulja, China being in a position to maintain order. China despatched Chung-hw, a Manchu of the highest rank, who had been notoriously concerned in the Tientsin massacre of 1870, to St Petersburg to negotiate a settlement. After some months of discussion a document was signed (September 1879), termed the treaty of Livadja, whereby China recovered, not indeed the whole, but a considerable portion of the disputed territory, on her paying to Russia five million roubles as the cost of occupation. The treaty was, however, received with a storm of indignation in China. Memorials poured in from all sides denouncing the treaty and its author. Foremost among these was one by Chang Chih-tung, who afterwards became the most distinguished of the viceroys, and governor-general of Hu-peh and Hu-nan provinces. Prince Chun, the emperor's father, came into prominence at this juncture as an advocate for war, and under these combined influences the unfortunate Chung-hw was tried and condemned to death (3rd of March 1880). For some months warlike preparations went on, and the outbreak of hostilities was imminent. In the end, however, calmer counsels prevailed. It was decided to send the Marquis Tseng, who in the meantime had become minister in London, to Russia to negotiate. A new treaty which still left Russia in possession of part of the Ili valley was ratified on the 19th of August 1880. The Chinese government, however, complained of the almost complete recovery of the whole extensive dominions which had at any time owed the imperial sway. The regions directly administered by the officers of the emperor extended from the borders of Siberia on the north to Annam and Burma on the south, and from the Pacific Ocean on the east to Kashgar and Yarkand on the west. There was also a fringe of tributary nations which still kept up the ancient forms of allegiance, and which more or less acknowledged the dominion of the central kingdom. The principal tributary nations then were Korea, Lu-chu, Annam, Burma and Nepal.

Korea was the first of the dependencies to come into notice. In 1866 some Roman Catholic missionaries were murdered, and about the same time an American vessel was burnt in one of the rivers and her crew murdered. China refused satisfaction, both to France and America, and suffered reprisals to be made on Korea without protest. America and Japan both desired to conclude commercial treaties for the opening up of Korea, and proposed to negotiate with China. China refused and referred them to the Korean government direct, saying she was unwilling to interfere in the affairs of independent states. As a result Japan concluded a treaty in 1876, in which the independence of Korea was expressly recognized. This was allowed to pass without protest, but as other nations proceeded to conclude treaties on the same terms China began to perceive her mistake, and endeavoured to tack on to each a declaration by the king that he was in fact a tributary—a declaration, however, which was quietly ignored. Japan, however, was the only power with which controversy immediately arose. In 1880 a faction fight, which had long been smouldering, broke out, headed by the king's father, the Tai Won Kun, in the course of which the Japanese legation was attacked and the whole Japanese colony had to flee for their lives. China sent troops, and by adroitly kidnapping the Tai Won Kun, order was for a time restored. The Japanese legation was replaced, but under the protection of a strong body of Japanese troops. Further revolutions and riots followed, in which the troops of the two countries took sides, and there was imminent danger of war. To obviate this risk, it was agreed in 1885 between Count Ito and Li Hung-Chang that both sides should withdraw their troops, the king being advised to engage officers of a third state to put his army on such a footing as would maintain order, and each undertook to give the other notice should it be found necessary to send troops again. In this way a modus vivendi was established which lasted till 1894.

We can only glance briefly at the domestic affairs of China during the period 1875-1882. The years 1877-1878 were marked by a famine in Shan-si and Shan-tung, which for duration and intensity has probably never been equaled. It was computed that 12 or 13 millions perished. It was vainly hoped that this loss of life due mainly to defective communications, would induce the Chinese government to listen to proposals for railway construction. The Russian scare had, however, taught the Chinese the value of telegraphs, and in 1881 the first line was laid from Tientsin to Shanghai. Further construction was continued without interruption from this date. A beginning also was made in naval affairs. The arsenal at Fuchow was turning out small composite gunboats, a training ship was bought and put under the command of a British officer. Several armoured cruisers were ordered from England, and some progress was made with the fortifications of Port Arthur and Wei-hai-wei. Forts were also built and guns mounted at Fuchow, Shanghai, Canton and other vulnerable points. Money for these purposes was abundantly supplied by the customs duties on foreign trade, and China had learnt that at need she could borrow from the foreign banks on the security of this revenue.

In 1881 the senior regent, the empress Tze'e An, was carried off by a sudden attack of heart disease, and the empress Tze'e Hsi remained in undivided possession of the supreme power during the remainder of the emperor Kung-su’s minority. Li Hung-Chang, firmly established at Tientsin, within easy reach of the capital, and as a result of his superintendant of northern trade, enjoyed a larger share of his imperial mistress's favour than was often granted by the ruling Manchus to officials of Chinese birth, and in all the graver questions of foreign policy his advice was generally decisive.

While the dispute with Japan was still going on regarding Korea, China found herself involved in a more serious quarrel in respect of another tributary state which lay on the southern frontier. By a treaty made between France and Annam in 1874, the Red river or Songkoi, which, rising in south-western China, flows through Tongking, was opened to trade, together with the cities of Haiphong and Hanoi situated on the delta. The object of the French was to find a trade route to Yun-nan and Sze-ch'uen from a base of their own, and it was hoped the Red river would furnish such a route. Tongking at this time, however, was infested with bands of pirates and cut-throats, many of whom were Chinese rebels or ex-rebels who had been driven across the frontier by the suppression of the Yun-nan and Taiping rebellions, conspicuous among them being an organization called the Black Flags. And in 1882 France sent troops to Tongking to restore order (the emperor Li Hung-Chang, to fulfill his promises in that respect) China began to protest, claiming that Annam was a vassal state and under her protection.

France took no notice of the protest, declaring that the claim had meant an archaeological interest, and that, in any case, China in military affairs was a quantité négligeable. France found, however, that she had undertaken a very serious task in trying to put down the forces of disorder (see Tongking). The Black Flags were, it was believed, being aided by Chinese troops shed armed from China, and as time went on more and more being confronted with regular Chinese soldiers. Several forts, well within the Tongking frontier, were known to be garrisoned by Chinese troops. Operations continued with more or less success to the end of 1885. In 1886, however, were desirous of an arrangement, and in May 1884 a convention was signed between Li Hung-Chang and a Captain Fournier, who had been commissioned ad hoc, whereby China agreed to withdraw her troops. Fournier, on his part, agreed to respect the fiction of Chinese suzerainty, and guarantee the frontier from attack by brigands. No date had been fixed in the convention for the evacuation of the Chinese garrisons, and Fournier was to supervise the departure of the Chinese forces. Li Hung-Chang, at the time announcing the fact to his government. In pursuance of this arrangement the French troops proceeded to occupy Langson on the date fixed (21st June 1884). The Chinese command refused to evacuate, alleging, in a despatch which has not been, in the French camp was competent to translate, that he had received no orders, and begged for a short delay to enable him to communicate with his superiors. The French command ordered an attack, which was repulsed with severe loss. Mutual recriminations ensued. From Paris there came a demand for a huge indemnity as reparation.
possessions—an ambition which was considered by British statesmen as not unreasonable. It did not, therefore, at all suit her purposes to see the rising power of Japan commanding the whole of the coast-line of Korea. Accordingly in the interval between the signature and the ratification of the treaty, invitations were addressed by Russia to the great powers to intervene with a view to its modification on the ground of the disturbance of the balance of power, and the menace to China which the occupation of Port Arthur by the Japanese would involve. France and Germany accepted the invitation, Great Britain declined. In the end the three powers brought such pressure to bear on Japan that she gave up the whole of her continental acquisitions, retaining only the island of Formosa. The indemnity was on the other hand increased by H. taels 30,000,000. For the time the integrity of China seemed to be preserved, and Russia, France and Germany could pose as her friends. Evidence was, however, soon forthcoming that Russia and France had not been disinterested in rescuing Chinese territory from the Japanese grasp. Russia now obtained the right to carry the Siberian railway across Chinese territory from Stryetensk to Vladivostok, thus avoiding a long detour, besides giving a grasp on northern Manchuria. France obtained, by a convention dated the 20th of June 1895, a rectification of frontier between the Mekong valley and certain railway and mining rights in Kiang-su; and the Yarens obtained concessions of land at Hankow for the purposes of settlement. Russia was also said to have negotiated a secret treaty, frequently described as the "Cassian Convention," but more probably signed by Li Hung-Chang at Moscow, giving her the right in certain contingencies to Port Arthur, which was to be refortified with Russian assistance. And by way of further securing her hold, Russia guaranteed a 4% loan of £15,000,000 issued in Paris to enable China to pay off the first installment of the Japanese indemnity.

The convention between France and China of the 20th of June 1895 brought China into sharp conflict with Great Britain. China, having by the Burma convention of 1886 agreed to recognize British sovereignty over Burma, her quondam feudatory, also agreed to a limitation of boundaries at the proper time. Effect was given to this last stipulation by a subsequent convention concluded in London (1st of March 1894), which traced the boundary line from the Shan states on the west as far as the Mekong river on the east. In the present dispute the rights of the semi-independent native territories over which suzerainty had been maintained, were disputed by both the kings of Ava and by the Chinese emperors. These territories were named Meng Lung and Kiang Hung—the latter lying partly on one side and partly on the other of the Mekong river, south of the point where it issues from Chinese territory. The boundary line was so drawn as to leave both these territories to China, but it was stipulated that China should not alienate any portion of these territories to any other power without the previous consent of Great Britain. Yielding to French pressure, and regardless of the undertaking she had entered into with Great Britain, China, in the convention with France in June 1895, so drew the boundary line as to cede to France that portion of the territory of Kiang Hung which lay on the left bank of the Mekong. Compensation was demanded by Great Britain from China for this breach of faith, and at the same time negotiations were entered into with France. These resulted in a joint declaration by the governments of France and Great Britain, dated the 13th of January 1896, by which it was agreed as regards boundary that the Mekong from the point of its source to the Aravul and Man Harum was to form the frontier, and that the Chinese frontier should be the dividing line between the possessions or spheres of influence of the two powers. It was also agreed that any commercial privileges obtained by either power in Yunnan or Sze-ch'uen should be open to the subjects of the other. The negotiations with China resulted in a further agreement, dated the 4th of February 1897, whereby considerable modifications in favour of Great Britain were made in the Burma boundary drawn by the 1894 convention.
While Russia and France were profiting by what they were pleased to call the generosity of China, Germany alone had so far received no reward for her share in the reoccupation of Liao-tung; but, in November 1897, she proceeded to help herself by seizing the Bay of Kiaochow in the province of Shan-tung. The act was done ostensibly in order to compel satisfaction for the murder of two German missionaries. A cessation was ultimately made by way of a lease for a term of ninety-nine years—Germany to have full territorial jurisdiction during the continuance of the lease, with liberty to erect fortifications, build docks, and exercise all the rights of sovereignty. In December the Russian fleet was sent to winter in Port Arthur, and though this was at first described as a temporary measure, its object was speedily disclosed by a request made, in January 1898, by the Russian ambassador in London that two British cruisers, then also anchored at Port Arthur, should be withdrawn "in order to avoid friction in the Russian sphere of influence." They left shortly afterwards, and their departure in the circumstances was regarded as a blow to Great Britain's prestige in the Far East. In March the Russian government perceptibly demanded a lease of Port Arthur and the adjoining anchorage of Talienwan—a demand which China could not resist without foreign support. After an acrimonious correspondence with the Russian government Great Britain acquiesced in the "fait accompli." The Russian occupation of Port Arthur was immediately followed by a concession to build a line of railway from that point northwards to connect with the Siberian trunk line in north Manchuria. As a counterpoise to the growth of Russian influence in the north, Great Britain obtained a lease of Wei-hai-wei, and formally took possession of it on its evacuation by the Japanese troops in May 1898.

After much hesitation the Chinese government had at last resolved to permit the construction of railways with foreign capital. An influential official named Sheng Hsuan-huai was appointed director-general of railways, and endeavoured to bring into negotiations with foreign capitalists for that purpose. A keen competition thereupon ensued between syndicates of different nationalities, and their claims being espoused by their various governments, an equally keen international rivalry was set up. Great Britain, though intimating her preference for the "open door" policy, meaning equal opportunity for all, yet found herself compelled to fall in with the general movement towards what became known as the "spheres of influence," and claimed the Yangtze valley as her particular sphere. This she did by the somewhat negative method of obtaining from the Chinese government a declaration that no part of the Yangtze valley should be alienated to any foreign power. A more formal recognition of the claim, as far as railway enterprise was concerned, was embodied in an agreement (28th of April 1899) between Great Britain and Russia, and communicated to the Chinese government, whereby the Russian government agreed not to seek for any concessions within the Yangtze valley, including all the provinces bordering on the great river, together with Cheh-kiang and Ho-nan, the British government entering into a similar undertaking in regard to the Chinese dominions north of the Great Wall.  

In 1899 Talienwan and Kiaochow were respectively thrown open by Russia and Germany to foreign trade, and, encouraged by these measures, the United States soon followed suit and in the same year a correspondence with the great European powers and Japan, with a view to securing their definite adhesion to the "open door" policy. The British government gave an unqualified approval to the American policy; and in May 1899, a memorandum which, though more guarded, were accepted at Washington as satisfactory. A further and more definite step towards securing the maintenance of the "open door" in China was the agreement concluded in October 1900 between the British and German governments. The signatories of the first two powers pledged themselves to endeavour to keep the ports open on the river, and to open international trade and economic activity, and to uphold this rule for all Chinese territory as far as (in the German counterpart) they could exercise influence; not to use the existing complications to obtain territorial advantages in Chinese dominions, and to seek to maintain undiminished the territorial condition of the Chinese empire. By a third article they reserved the right to discuss, if notified by the Chinese government in case of any such action on the part of their interests in China, should any other power use those complications to obtain such territorial advantages under any form whatever. On the submission of the agreement to the powers interested, Australia, Canada, France, Germany, Japan, Russia, and the United States immediately expressed reservations—Japan first obtaining assurances that she signed on the same footing as an original signatory. The United States accepted the first two articles, but expressed no opinion on the third. Russia construed the first as limited to ports actually open in regions where the two signatories exercise "their influence, and favourably entertained it in that sense, ignoring the reference to other forms of economic activity. She fully accepted the second, and observed that in the Navigation Treaty, as subsequently signed, the third, she would modify her attitude according to circumstances.

Meanwhile, negotiations carried on by the British minister at Peking during 1898 resulted in the grant of very important privileges to the British commerce. The payment of the second instalment of the Japanese indemnity was becoming due, and it was much discussed how and on what terms China would be able to raise the amount. The Russian government, as has been stated, had made China a loan of the sum required for the first portion of the indemnity, viz. $15,000,000, taking a charge on the customs revenue as security. The British government was urged to make a like loan of $16,000,000 both as a matter of friendship to China and as a counterpoise to the Russian influence. The Chinese government had been disposed to meet this loan with very favourable terms financially to the Chinese, but at the last moment they drew back, being overawed, as they said, by the threatening attitude of Russia. Taking advantage of the position which France and Germany had already found at the head of the Tsang-tse-Yam, besides the declaration as to the non-alienation of the Yangtsze valley above mentioned, an undertaking to throw the whole of the inland waterways open to steam traffic. The Chinese government, however, at the time, was in the hands of the "great-generals" of customs (then held by Sir Robert Hart) who should always be held by an Englishman so long as the trade of Great Britain was greater than that of any other nation. Minor concessions were also made, and the opening of the waterways by far the greatest advance that had been made since 1860.

Of still greater importance were the railway and mining concessions granted during the same year (1898). The Chinese government had been urged by the diplomatic department to dispose of railway and mining concessions to the great powers of the Japanese War, but hoped to be able to retain the control in their own hands. The masterful methods of Russia and Germany had obliged them to surrender this control so far as concerned Manchuria and Shan-tung. In the Yangtze valley, Sheng, the director-general of railways, had been negotiating with several competing syndicates. One of these was a Franco-Belgian syndicate, which was endeavouring to obtain the trunk line from Hankow to Peking under the Chinese government for the same work, and as the line lay mainly within the British sphere it was considered unreasonable to expect it should be given to the latter. At a critical moment, however, the French and Russian ministers interve ned and undertook to take over the affairs of the Franco-Belgian company. The Yamen had a few days before explicitly promised the British minister that the contract should not be ratified without his having an opportunity of seeing it. As a penalty for this breach of faith, and the consequent loss of the line, both the British minister prevailed on the immediate grant of all the railway concessions for which British syndicates were then negotiating, and on terms not inferior to those granted to the Belgian line. In this way all the lines in the lower Yangtsze, as also the Chinese Mining Companies' lines, were secured. A contract for a trunk line from Canton to Hankow was negotiated in the latter part of 1898 by an American company.

There is little doubt that the powers, engrossed in the diplomatic conflicts of which Peking was the centre, had entirely underrated the reactionary forces gradually muster ing for a struggle against the aggressive spirit of Western civilization. The lamentable consequences of administrative corruption and incompetence, and the superiority of foreign methods which had been amply illustrated by the Japanese War, had at first produced a considerable impression, not only upon the more enlightened commercial classes, but even upon many of the younger members of the national classes in China. The Dowager-empress, who, in spite of the emperor Kuang-su having nominally attained his majority, had retained practical control of the supreme power until the conflict with Japan, had been held, not unjustly, to blame for the disasters of the war, and even before its conclusion the young emperor was adjudged by some of the most responsible among his own subjects to shake himself free from the baneful restraint of "petticoat government."
and himself take the helm. In the following years a reform movement, undoubtedly genuine, though opinions differ as to the value of the popular support which it claimed, spread throughout the central and southern provinces of the empire. One of the most significant symptoms was the relatively large demand which suddenly arose for the translations of foreign works and similar publications in the Chinese language which philantropic societies, such as that for the Diffusion of Christian and General Knowledge amongst the Chinese, had been trying for some time past to popularize, though hitherto with scant success. Chinese newspapers published in the treaty ports spread the ferment of new ideas far into the interior. Fifteen hundred young men of good family applied to enter the foreign university at Peking, and in some of the provincial towns the Chinese themselves subscribed towards the opening of foreign schools. Reform societies, which not infrequently enjoyed official countenance, sprang up in many of the large towns, and found numerous adherents amongst the younger literati. Early in 1898 the emperor, who had gradually emancipated himself from the dowager-empress's control, summoned several of the reform leaders to Peking, and requested them to give advice with regard to the business which he felt should be introduced into the government of the empire. Chief amongst these reformers was Kang Yu-wei, a Cantoneze, whose scholarly attainments, combined with novel teachings, earned him from his followers the title of the "Modern Sage." Of his more or less active sympathizers who had subsequently to suffer with him in the cause of reform, the most prominent were Chang Yin-huan, a member of the grand council and of the Tsung-Li-Yamen, who had represented his sovereign at Queen Victoria's jubilee in 1897; Chin Pao-chen, governor of Hu-nan; Liang Chichao, the editor of the reformers' organ, Chinese Progress; Su Chiching, a reader of the Hanlin College, the educational stronghold of Chinese conservatism; and his son Su In-chi, also a Hanlin man, and provincial chancellor of public instruction in Hu-nan.

It soon became evident that there was no more enthusiastic advocate of the new ideas than the emperor himself. Within a few months the vermilion pencil gave the imperial sanction to a succession of edicts which, had they been carried into effect, would have amounted to a revolution as far-reaching as that which the ascension of the first of a new dynasty had accomplished. The feudal system of examinations for the public service was to be altogether superseded by a new schedule based on foreign learning, for the better promotion of which a number of temples were to be converted into schools for Western education; a state department was to be created for the translation and dissemination of the standard works of Western literature and science; even the scions of the ruling Manchu race were to be compelled to study foreign languages and travel abroad; and last, but not least, all useless offices both in Peking and in the provinces were to be abolished. A further edict was even reported to be in contemplation, doing away with the quee or pigtail, originally imposed upon the Chinese by their Manchu conquerors as a badge of subjection, had gradually become the most characteristic and most cherished feature of the national dress. But the bureaucracy of China, which had fattened for centuries on corruption and ignorance, had no taste for self-sacrifice. Other vested interests felt themselves equally threatened, and behind them stood the whole latent force of popular superstition and tradition, which, on the waning of the dowager-empress, saw her opportunity. The Summer Palace, to which she had retired, had been for some time the centre of resistance to the new movement, and in the middle of September 1898 a report became current that, in order to put an end to the obstruction which hampered his reform policy, the emperor intended to seize the person of the dowager-empress and have her deported into the interior. Some colour was given to this report by an official announcement that the emperor would hold a review of the foreign-drilled troops at Tientsin, and had summoned Yuan Shih-kai, their general, to Peking in order to confer with him on the necessary arrangements. But the reformers had neglected to secure the goodwill of the army, which was still entirely in the hands of the reactionaries. During the night of the 20th of September the palace of the empress was occupied by the soldiers, and on the following day Kwang-su, who was henceforth virtually a prisoner in the hands of the empress, was made to issue an edict restoring her regency. Kang Yu-wei, warned at the last moment by an urgent message from the emperor, succeeded in escaping, but many of the most prominent reformers were arrested, and six of them were promptly executed. The Peking Gazette announced a few days later that the emperor himself was dangerously ill, and his life might well have been despaired of had not the British minister represented in very emphatic terms the serious consequences which might ensue if anything happened to him. Drastic measures were, however, adopted to stamp out the reform movement in the provinces as well as in the capital. The reform edicts were cancelled, the reformers' associations were dissolved, their newspapers suppressed, and those who did not care to save themselves by a hasty recantation of their errors were imprisoned, proscribed or exiled. In October the reaction had already been accompanied by such a recrudescence of anti-Christian feeling that the foreign ministers at Peking had to bring up a formal note of protest and to demand the removal from the capital of the disorderly Kan-suh soldiery which subsequently played so sinister a part in the troubles of June 1900. But the unpleasant impression produced by these incidents was in a great measure removed by the demonstrative reception which the emperor Tsz'e Hsi gave on the 15th of October to the wives of the foreign representatives—an act of courtesy unprecedented in the annals of the Chinese court.

The reactionary tide continued to rise throughout the year 1899, but it did not appear materially to affect the foreign relations of China. Towards the end of the year the brutal murder of Mr Brooks, an English missionary, in Shan-tung, had compelled attention to a popular movement which had been spreading rapidly throughout that province and the adjoining one of Chih-li with the connivance of certain high officials, if not under their direct patronage. The origin of the "Boxer" movement is obscure. Its name is derived from a literal translation of the Chinese sign sz'hs'ai, which means "spear-societies." In the beginning the danger by defeciting what might have been a revolutionary movement into anti-Christian channels, or whether with Oriental heedlessness they had allowed it to grow until they were powerless to control it, they had unquestionably resolved to take it under their protection before the foreign representatives at Peking had realized its gravity. The outrages upon native Christians and the threats against foreigners generally went on increasing. The Boxers openly displayed on their banners the device: "Exterminate the foreigners and save the dynasty," yet the representatives of the powers were unable to obtain any effective measures against the so-called "rebels," or even a definite condemnation of their methods.1

Four months (January–April 1900) were spent in futile interviews with the Tsung-Li-Yamen. In May a number of Christian villages were destroyed and native converts massacred near the capital. On the 2nd of June two English missionaries, Mr Robinson and Mr Norman, were murdered at Yung Ching, 40 m. from Peking. The whole country was overrun with bands of Boxers, who tore up the railway and set fire to the stations at different points on the Peking-Tientsin line. Fortunately a

---

1 The religious aspect of the Boxer movement gave it strength. Its disciples believed that the spirits which defended China were incensed by the introduction of Western methods and ideals. Many of them believed themselves to be invulnerable to any Western weapon. (See Lord W. Cecil, Changing China, 1910, ch. 1.)
mixed body of marines and bluejackets of various nationalities, numbering 18 officers and 389 men, had reached Peking on the 1st of June for the protection of the legations. The whole city was in a state of turmoil. Murder and pillage were of daily occurrence. The pro-Germans Prince Tuan (grandson of the emperor Tao-Teh), and the Manchus generally, together with the Kan-su soldiers under the notorious Tung-fu-hsiang, openly sided with the Boxers. The European residents and a large number of native converts took refuge in the British legation, where preparations were hastily made in view of a threatened attack. On the 11th the chancellor of the Japanese legation, Mr Sugiyama, was murdered by Chinese soldiers. On the night of the 13th most of the foreign buildings, churches and mission houses in the eastern part of the Tatar city were pillaged and burnt, and hundreds of native Christians massacred.

On the 20th of June the German minister, Baron von Ketteler, was murdered whilst on his way to the Tsung-Li-Yamen. At 4 P.M. on the afternoon of the 20th the Chinese troops opened fire on the legations. The general direction of the defence was undertaken by Sir Claude Macdonald, the British minister. Meanwhile Peking had been completely cut off since the 14th from all communication with the outside world, and in view of the gravity of the situation, naval and military forces were being hurried up by all the powers to the Gulf of Chih-li. On the 10th of June Admiral Sir E. Seymour had already left Tientsin with a mixed force of 2000 British, Russian, French, Germans, Austrians, Italians, Americans and Japanese, to repair the railway and restore communications with Peking. But his expedition met with unexpectedly severe resistance, and it had great difficulty in making its retreat after suffering heavy losses. When it reached Tientsin again on the 26th of June, the British contingent of 915 men had alone lost 124 killed and wounded out of a total casualty list of 62 killed and 218 wounded. The Chinese had in the meantime made a determined attack upon the foreign settlements at Tientsin, and the communication between the city and the sea being also threatened, the Taku forts at the mouth of the Pei-ho were captured by the allied admirals on the 17th. The situation at Tientsin nevertheless continued precarious, and it was not till the arrival of considerable reinforcements that the troops of the allied powers were able to assume the offensive, taking the native city by storm on July 14th, at a cost, however, of over 700 killed and wounded. Even in this emergency international jealousy had grievously delayed the necessary concentration of forces. No power was so favourably situated to take immediate action as Japan, and the British government, who had strongly urged her to act speedily and energetically, undertook at her request to sound the other powers with regard to her intervention. No definite objection was raised, but the replies of Germany and Russia barely disguised their ill-humour.

Great Britain herself went so far as to offer Japan the assistance of the British treasury, in case financial difficulties stood in the way, but on the same day on which this proposal was telegraphed to Tokyo (6th of July), the Japanese government had decided to embark forthwith the two divisions which it had already mobilized. By the beginning of August one of the Indian brigades had also reached Tientsin together with smaller reinforcements sent by the other powers, and thanks chiefly to the energetic counsels of the British commander, General Sir Alfred Gaselle, a relief column, numbering 20,000 men, at last set out for Peking on the 4th of August, a British naval brigade having started up river the previous afternoon. After a series of small engagements and very trying marches it arrived within striking distance of Peking on the evening of the 13th. The Russians tried to steal a march upon the allies during the night, but were chased at the walls and suffered heavy losses. The Japanese attacked another point of the Chinese defences, and with the assistance of the British were able to take possession of the Russian line of advance. The British contingent was more fortunate, and skilfully guided to an unguarded water-gate, General Gaselle and a party of Sikhs were the first to force their way through to the British legation. About 2 p.m. on the afternoon of the 14th of August, the long siege was raised.

For nearly six weeks after the first interruption of communications, no news reached the outside world from Peking except a few shots from the German missionary's residence almost at an.Chinese lines by native runners, urging the imperative necessity of prompt relief. During the greater part of that period the foreign quarter was subjected to heavy rifle and artillery fire, and the continuous fighting at close quarters with the hordes of Chinese regulars, as well as Boxers, decimated the scanty ranks of the defenders. The supply of both ammunition and food was slender. But the heroism displayed by civilians and professional combatants alike was inexcusable. In their anxiety to burn out the British legation, the Chinese did not hesitate to set fire to the adjoining buildings of the Hanlin, the ancient seat of Chinese classical learning, and the storehouse of priceless literary treasures and state archives. The Fu, or palace, of Prince Su, separated only by a canal from the British legation, formed the centre of the international position, and was held with indomitable valour by a small Japanese force under Commodore Inukai, assisted by a few Chinese volunteers of other* nationalities and a number of Christian Chinese. The French legation on the extreme right, and the section of the city wall held chiefly by Germans and Americans, were also points of vital importance which had to bear the brunt of the Chinese attack.

Little is known as to what passed in the councils of the Chinese court during the siege.1 But there is reason to believe that throughout that period grave divergences of opinion existed amongst the highest officials. The attack upon the legations was immediately sanctioned by the dowager-empress, acting upon the advice of Prince Tuan and the extreme Manchu party, at a grand council held during the night of the 18th/19th June, upon receipt of the news of the capture of the Taku forts by the international forces. The emperor himself, as well as Prince Ching and a few other influential mandarins, strongly protested against the empress’s decision, but it was acclaimed by the vast majority of those present. Three members of the Tsung-Li-Yamen, commanded by Tsung-Li, the dowager-empress’s son, then issued the order of an imperial edict ordering the massacre of all foreigners throughout the provinces, and most of the Manchu nobles and high officials, and the eunuchs of the palace, who played an important part in Chinese politics throughout the dowager-empress’s tenure of power, were burnt and with the Boxers. But it was noted by the defenders of the legations that Prince Ching’s troops seldom took part, or only in a half-hearted way, in the fighting, which was chiefly conducted by Tsung-Li’s and the dowager-empress’s bodyguard. It was said that the Chinese possessed only spasmodically brought into play. Nor did any of the attacking parties ever show the fearlessness and determination which the Chinese had somewhat unexpectedly displayed during the fighting at and around Tientsin. Nevertheless, the position of the defenders at the end of the first four weeks of the siege had grown well-nigh desperate. Mining and incendiarism proved far greater dangers than shell and shot. Suddenly, just when things were looking blackest, on the 8th of July the Chinese ceased firing, and a sort of informal armistice secured a period of respite for the beleaguered Europeans. The capture of the native city of Tientsin by the allied forces had shaken the self-confidence of the Chinese authorities, who had hitherto not only countenanced, but themselves directed the hostilities.2 Desultory fighting, nevertheless, continued, and grave fears were entertained that the approach of the relief column would prove the signal for a desperate attempt to rush the legations. This attempt was made, but failed. The relief, however, came not a day too soon. Of the small band of defenders which, including civilian volunteers, had never mustered 500, 65 had been killed and 131 wounded. Among the French and Americans and all the allies, the situation was at the Pei-tang, the Roman Catholic northern cathedral and mission house, where, with the help of a small body of French and Italian marines, Mgr Favier had organized an indomitable garrison, and was himself to perish for his country's sakes.

1The diary of a Manchu noble printed in China under the Empress Dowager (1910) by J. O. Bland and E. Backhouse throws light on the subject. It was to Jung-Lu, father-in-law of Prince Ching, that the legations owed their escape from extermination.

2It was at this time (July 12th) that the first message of the civil authorities to the world was published, and that the besieged reached its culminating point. Circumstantial accounts of the fall of the legations and the massacre of their inmates were circulated in Shanghai and found general credence. It was not till near the end of the siege that an authentic message from the American minister proved these fears to be premature.
of August, a relief party was despatched to their assistance from the legations.

The ruin wrought in Peking during the two months' fighting was appalling. Apart from the wholesale destruction of foreign property in the Tatar city, and of Chinese as well as European buildings in the vicinity of the legations, the wealthiest part of the Chinese city had been laid in ashes. The flames from a foreign drug store fired by the Boxers had spread to the adjoining buildings, and finally consumed the whole of the business quarter with all its invaluable stores of silks, curiosities, furs, &c. The retribution which overtook Peking after its capture by the international forces was scarcely less terrible. Looting was for some days almost universal. Order was, however, gradually restored, first in the Japanese and then in the British and American quarters, though several months elapsed before there was any real revival of native confidence.

So unexpected had been the rapid and victorious advance of the allies, that the dowager-empress with the emperor and the rest of the court did not actually leave Peking until the day after the legations had been burned. But the northern and western portions of the Tatar city had not yet been occupied, and the fugitives made good their escape on the 15th. When the allies some days later marched through the Forbidden City, they only found a few eunuchs and subordinate officials in charge of the imperial apartments. At the end of September, Field Marshal Count von Waldersee, with a German expeditionary force of over 20,000 men, arrived to assume the supreme command conferred upon him with the more or less willing assent of the other powers.

The political task which confronted the powers after the occupation of Peking was far more arduous than the military one. The action of the Russians in Manchuria, even in a treaty port like Niu-chwang, the seizure of the railway line not only to the north of the Great Wall, but also from Shan-hai-kwan to Peking, by the Russian military authorities, and the appropriation of an extensive line of river frontage at Tientsin as a Russian "settlement," were difficult to reconcile with the pacific assurances of disinterestedness which Russia, like the rest of the powers, had officially given. Great anxiety prevailed as to the effect of the flight of the Chinese court in other parts of the empire. The anti-foreign movement had not spread much beyond the northern provinces, in which it had had the open support of the throne and of the highest provincial officials. But among British and Americans alone, over 200 defenseless foreigners, men, women and children, chiefly missionaries, had fallen victims to the treachery of high-placed mandarins like Yü Hsien, and hundreds of others had had to fly for their lives, many of them owing their escape to the courageous protection of petty officials and of the local gentry and peasantry. In the Yangtsze valley order had been maintained by the energy of the viceroy of Nanking and Wu-chang, who had acted throughout the critical period in loyal co-operation with the British consul and naval commanders, and had courageously disregarded the imperial edicts issued during the ascendancy of the Boxers. After some hesitation, an Italian brigade, followed by French, German and Japanese contingents, had been landed at Shanghai for the protection of the settlements, and though the viceroy, Liu Kun-yi, had welcomed British support, and even invited the joint occupation of the Yangtsze forts by British and Chinese troops, the appearance of other European forces in the Yangtsze valley was viewed with great suspicion. In the south there were serious symptoms of unrest, especially after Li Hung-Chang had left Canton for the north, in obedience, as he alleged at the time, to an imperial edict which, there is reason to believe, he invented for the occasion. The Chinese court, after one or two intermediate halts, had retired to Si-gan-fu, one of the ancient capitals of the empire, situated in the inaccessible province of Shen-si, over 600 m. S.W. of Peking. The influence of the ultra-reactionaries, headed by Prince Tuan and General Tung-fu-hsiang, still dominated its councils, although credentials were sent to Prince Ching and to Li Hung-Chang, who, after waiting upon events at Shanghai, had proceeded to Peking, authorizing them to treat with the powers for the re-establishment of friendly relations.

The harmony of the powers, which had been maintained with some difficulty up to the relief of the legations, was subjected to a severe strain as soon as the basis of negotiations with the Chinese government came to be discussed. While for various reasons Russia, Japan and the United States were inclined to treat China with great indulgence, Germany insisted upon the signal punishment of the guilty officials as a conditio sine qua non, and in this she had the support not only of the other members of the Triple Alliance, but also of Great Britain, and to some extent even of France, who, as protector of the Roman Catholic Church in Eastern countries, could not allow the authors of the atrocities committed upon its followers to escape effectual punishment. It was not until after months of laborious negotiations that the demands to be formally made upon the Chinese government were embodied in a joint note signed by all the foreign ministers on the 20th and 21st of December 1900. The demands were subsequently modified or withdrawn by the different countries.

Honourable reparation for the murder of von Ketteler and of Mr Sugiyama, to be made in a specified form, and expiatory monuments to be erected in cemeteries where foreign tombs had been desecrated. The most severe punishment befitting their crimes was to be inflicted upon those persons charged with the perpetration of the outrages of 18 and 19 October, and upon others to be designated later by the foreign ministers, and the official examinations were to be suspended in the cities where foreigners had been murdered or ill-treated. An equitable indemnity, guaranteed by financial measures available to the powers, was to be paid to states, societies and individuals, including Chinese who had suffered because of their employment by foreigners, but not including Chinese Christians who had suffered only on account of their faith. The importation of arms or matériel was to be forbidden; permanent legation guards were to be maintained at Peking, and the diplomatic quarter was to be fortified, while communication with the sea was to be secured by the evacuation of a number of military points on the outskirts of the Chinese forts, including the Taku forts, between the capital and the coast. Proclamations were to be posted throughout China for two years, threatening death to the members of anti-foreign societies, and recording the punishment of the ringleaders in the late outrages: and the viceroy, governors and provincial officials were to be declared by imperial edict responsible, on pain of immediate dismissal and perpetual disability to hold office, for anti-foreign outrages on Chinese, and even for the failure to prevent them. The payment of a part of the indemnity to be made to the occupation of Peking and of the provinces by foreign troops.

Under instructions from the court, the Chinese plenipotentiaries affixed their signatures on the 14th of January 1901 to a protocol, by which China pledged herself to accept these terms in principle, and the conference of ministers then proceeded to discuss the definite form in which compliance with them was to be exacted. This further stage of the negotiations proved even more laborious and protracted than the preliminary proceedings. No attempt was made to raise the question of the dowager-empress's responsibility for the anti-foreign movement, as Russia had from the first hesitated to go further. But it was, in an oblique way, technically termed "the dynastic question." But even with regard to the punishment of officials whose guilt was beyond dispute, grave divergences arose between the powers. The death penalty was ultimately avoided in the case even of such conspicuous offenders as Prince Tuan and Tung-fu-hsiang, but the notorious Yü Hsien and two others were decapitated by the Chinese, and three other metropolitan officials were ordered to commit suicide, whilst upon others sentences of banishment, imprisonment and degradation were passed, in accordance with a list drawn up by the foreign representatives. The question of the punishment of provincial officials responsible for the massacre of scores of defenceless men, women and children was unfortunately reserved for separate treatment, and when it came up for discussion it became impossible to preserve even the semblance of unanimity, the Russian minister at once taking issue with his colleagues, although he had originally pledged himself as formally as the others to the principle. Count
Landsdorff frankly told the British ambassador at St Petersburg that Russia took no interest in missionaries, and as the foreigners massacred in the provinces belonged mostly to that class, she declined to join in the action of the other powers.

The real explanation of Russia's cynical secession from the concert of powers on this important issue must be sought in her anxiety to conciliate the Chinese in view of the separate negotiations in which she was at the same time engaged with China in respect of Manchuria. When the Boxer movement was at its height at the end of June 1900, the Chinese authorities in Manchuria had wantonly "declared war" against Russia, and for a moment a great wave of panic seems to have swept over the Russian administration, civil and military, in the adjoining provinces. The reprisals exercised by the Russians were proportionately fierce. The massacre at Blagoveshchensk, where 5000 Chinese—men, women and children—were flung into the Amur by the Cossacks, was only one incident in the reign of terror by which the Russians sought to restore their power and their prestige. The resistance of the Chinese troops was soon overcome, and Russian forces overran the whole province, occupying every port (except Niu-chwang). The Russian government officially disclaimed all responsibility for the proclamations issued by General Gribsky and others, foreshadowing, if not actually proclaiming, the annexation of Chinese territory to the Russian empire. But Russia was clearly bent on seizing the opportunity for securing a permanent hold upon Manchuria. In December 1900 a preliminary agreement was made between M. Korostovetz, the Russian administrator-general, and Tseng, the Tatar general at Mukden, by which the civil and military administration of the whole province was virtually placed under Russian control. In February 1901 negotiations were opened between the Russian government and the Chinese minister at St Petersburg for the conclusion of a formal convention of a still more comprehensive character. In return for the restoration to China of a certain measure of civil authority in Manchuria, Russia was to be confirmed in the possession of exclusive military, civil and commercial rights, constituting in all but name a protectorate, and she was also to acquire preferential rights over all the outlying provinces of the Chinese empire bordering on the Russian dominions in Asia. The clauses relating to Chinese Turkestan, Kashgar, Yarkand, Khotan and Mongolia were subsequently stated to have been dropped, but the convention nevertheless provoked considerable opposition both in foreign countries and amongst the Chinese themselves. Most of the powers, including Germany, who, however, denied that the Anglo-German agreement of the 16th of October 1900 applied to Manchuria,1 advised the Chinese government not to pursue separate negotiations with one power whilst collective negotiations were in progress at Peking, and both Japan and Great Britain pressed for definite information at St Petersburg with regard to the precise tenor of the proposed convention. At the same time the two viceroys of the lower Yangtse memorialized the throne in the strongest terms against the convention, and these protests were endorsed not only by the great majority of Chinese officials of high rank throughout the provinces, but by popular meetings and influential guilds and associations. In the cities of Chih-tung and Liu Kun-yi,2 took the extreme step of warning the throne that they would be unable to recognize the convention, even if it were ratified, and notwithstanding the pressure exercised in favour of Russia by Li Hung-Chang, the court finally instructed the Chinese minister at St Petersburg to decline his signature. The attitude of Japan, where public feeling ran high, was equally significant, and on the 3rd of April the Russian government issued a circular note to the powers, stating that, as the generous intentions of Russia had been misconstrued, she withdrew the proposed convention.

The work of the conference at Peking, which had been temporarily disturbed by these complications, was then resumed. Friction between European troops of different nationalities and an Anglo-Russian dispute over the construction of certain roads and railway sidings at Tientsin showed that an international occupation was fraught with manifold dangers. The question of indemnities, however, gave rise to renewed friction. Each power drew up its own claim, and whilst Great Britain, the United States and Japan displayed great moderation, other powers, especially Germany and Italy, put in claims which were strangely out of proportion to the services rendered by their military and naval forces. It was at last settled that China should pay altogether an indemnity of 450 million taels, to be secured (1) on the unhypothecated customs of the Russian customs administered by the imperial maritime customs, the import duties being raised forthwith to an effective 5% basis; (2) on the revenues of the "native" customs; (3) on the extraordinary revenue of the salt gabelle. Finally the peace protocol was drawn up in a form which satisfied all the powers as well as the Chinese court. The formal signature was, however, delayed at the last moment by a fresh difficulty concerning Prince Chun's peninsular mission to Berlin. This prince, an amiable and enlightened youth,3 son of the Prince Chun who was the emperor Hien-feng's brother, and thus himself half-brother to the emperor Kwang-su, had reached Basel towards the end of August on his way to Germany, when he was suddenly informed that he and his suite would be expected to perform kowtow before the German emperor. The prince presented this unexpected demand, and referred home for instructions. The Chinese court appear to have remained obdurate, and the German government perceived the mistake that had been made in exacting from the Chinese prince a form of homage which Western diplomacy had for more than a century refused to yield to the Son of Heaven, on the ground that it was barbarous and degrading. The point was waived, and Prince Chun was received in solemn audience by the emperor William at Potsdam on the 4th of September. Three days later, on the 7th of September, the peace protocol was signed at Peking.

The articles recorded the steps to be taken to satisfy the demands of the powers as to commerce. Article 11 provided for the amendment of existing treaties of commerce and navigation, and for river conservancy measures at Tientsin and Shanghai. The British government appointed a special commission, with Sir J. Mackay, member of the council of India, as chief commissioner, to proceed to Shanghai to carry on the negotiations, and a commercial treaty was signed at Shanghai on the 6th of September 1902, by which existing obstacles to foreign trade, such as likin, &c., were removed, regulations were made for facilitating steamer navigation on inland waters, and several new ports were opened to foreign commerce.

In accordance with the terms of the protocol, all the foreign troops, except the legation guards, were withdrawn from Peking on the 17th of September, and from the rest of China, except the garrisons at the different points specified along the line of communications, by the 22nd of September. On the 7th of October it was announced that the Chinese court had left Si-kanfu on its way back to the northern capital. A month later (27th of November) the death of Li Hung-Chang at Peking removed, if not the greatest of Chinese statesmen, at any rate the one who had enjoyed the largest share of the empress-dowager's confidence.

(E)—From 1902 to 1910.

The events connected with the Boxer rising and its suppression demonstrated even more forcibly than had the war with Japan in 1894–1895 the necessity for the adoption of

---

1 In negotiating this agreement Lord Salisbury appears to have been greatly influenced by the aggressive features of Russia's action in North China, while Germany appears to have been actuated by a desire to forestall isolated action by Great Britain in the Yangtsze basin. In Germany the agreement was known as the Yangtsze Agreement. Great Britain held, however, that it applied equally to Manchuria.

2 Liu Kun-yi died in 1902. In the same year died Tso-mu, the viceroy of Canton. In these men China lost two of her most capable and enlightened officials.

3 Prince Chun was born in 1882. He was the first member of the imperial family to be sent on a foreign mission.
Western methods in many departments of life and administration if China was to maintain the position of a great power.

The necessity for a thorough reform of the administration was widely recognized in 1901, and among the progressive classes of the community much dissatisfaction was manifested because the powers had failed to insist, in the conditions of peace, on a reorganization of the machinery of government. The Yangtze viceroy, the viceroy at Canton, Yuan Shih-kai and other high mandarins repeatedly memorialized the throne to grant effective reforms. While at Si-gan-fu the court did in fact issue several reform decrees, but at the same time all authority remained in the hands of reactionaries. There had been an awakening in China, but another lesson—afforded a few years later by the Russo-Japanese War—was needed before the reform party was able to gain real power.

For three or four years following the signing of the peace protocol of 1901 it seemed indeed that there would be little change in the system of government, though in some directions a return to the old state of affairs was neither possible nor desired. On the 7th of January 1902 the court returned to Peking—a step which marked the restoration, more or less, of normal conditions. The failure of the Boxer movement, in which, as has been shown, she was deeply implicated, had impaired the prestige of the empire, and even in the terms with foreign powers, but the reform edicts issued from Si-gan-fu remained largely inoperative, though some steps were taken to promote education on Western lines, to readjust the land tax, and especially to reorganize the military forces (though on provincial rather than on a national basis). The building of railways was also pushed on, but the dowager empress was probably at heart as reactionary as she had proved in 1898. The emperor himself from his return to Peking until the day of his death appeared to have little influence on public affairs.

The most disquieting feature of the situation in the years immediately following the return of the court to Peking was the continued efforts of Russia to obtain full control of Manchuria and a predominant influence in north China. The Chinese government was powerless to stem the advance of Russia, and the dowager empress herself was credited with indifference to the fate of Manchuria. It was the menace to other powers, notably Japan, involved in Russia's action which precipitated an issue in which the destinies of China were involved. Considering the resulting of that struggle (the Russo-Japanese War) the chance China of 1902-1905 may be but another lesson.

The dowager empress from the day of her return from Si-gan-fu set herself to conciliate the foreign residents in Peking. Many foreign onlookers were gathered on the wall of the Tatar city to witness the return of the court, and to these the dowager empress made a deep bow twice, an apparently trivial incident which made a lasting impression. On the 1st of February following the dowager empress received the ladies of the various embassies, when she bewailed the attack on the legations, entertained her guests to tea and presented each with articles of jewelry, and from that time onward, as occasion offered, Ts'ze Hsi exchanged compliments and civilities with the foreign ladies in Peking. Moreover, Sir Robert Hart—aftet having been nearly forty years in China—was now presented at court, as well as Bishop Favier and others. Henceforth attacks on foreigners received no direct encouragement at court. Tung Fu-lisian, who had been banished to the remote province of Kam-sih, had at his command there his old Boxer troops, and his attitude caused anxiety at the end of 1902. He was said to have received support from Prince Tung, who had been pardoned, but the evidence adduced proved that the power or the intention of these reactionaries to create trouble had been miscalculated. There were indeed serious Boxer disturbances in Sze-chuen in 1902, but they were put down by a new viceroy sent from Peking. Notwithstanding the murder of fifteen missionaries during 1902-1905, there was in general a marked improvement in the relations between the missionaries, the official classes and the bulk of the people, and an eagerness was shown in several provinces to take advantage of their educational work. This was specially marked in Hu-nan, a province which had been for long hostile to missionary endeavours. Illustrative of the attitude of numbers of high officials was the attendance of the viceroy of Sze-ch’uen, with the whole of his staff, at the opening in 1905 at Cheng-tu of new buildings of the Canadian Missionist Mission. This friendly attitude towards the missions was due in part to the influence of Chinese educated abroad and also, to a large extent, to the desire to take advantage of Western culture. The spread of this new spirit was coincident with an agitation for independence of foreign control and the determination of the Chinese to use modern methods to attain their ends. Thus in 1905 there was an extensive boycott of American goods throughout China, as a retaliatory measure for the exclusion of Chinese from the United States. Regarding China as a whole the attitude of the people towards Europeans was held to indicate that the general view was, not that the Boxer teaching was false, but that the spirits behind Western religion were more powerful than those behind Boxerdom. The spiritual prestige of Christianity and respect for the Western nation were increased by the success of the Boxers. The British expedition to Tibet in 1904, the occupation of Lhasa in August of that year, the flight of the Dalai Lama to Mongolia, gave grave concern to the Chinese government—which showed much persistence in enforcing its suzerain rights in Tibet—but did not, apparently, cause any ill-feeling towards Great Britain among the Chinese people—who viewed with seeming equanimity the flight of the head of the Buddhist religion from the headquarters of that faith. The country generally was peaceful, a rebellion in Kwangsi—where a terrible famine occurred in 1903—being suppressed in 1904 by the forces of the viceroy at Canton.

The expiatory measures required of China in connexion with the Boxer rising were carried through. China during 1902 recovered possession of the Peking-Tientsin railway and of the city of Tientsin, which was evacuated by the foreign troops in August of that year. The foreign troops were also all withdrawn from Shanghai by January 1903. The conclusion of a new commercial treaty between Great Britain and China in September 1902 has already been recorded. The payment of indemnity instalments occasioned some dispute owing to the fall in silver in 1902, but the rise in the value of the tael in subsequent years led China to agree to the payment of the indemnity on a gold basis. The increase in revenue was a notable feature of the maritime customs in 1903—1905. This result was in part due to the new arrangements under the commercial treaty of 1902, and in part to the opening up of the country by railways. In especial the great trunk line from Peking to Hankow was pushed on. The line, including a bridge nearly 2 m. long over the Yellow river was completed and opened for traffic in 1905. The first section of the Shanghai-Nanking railway was opened in the same year. At this time the Chinese showed a strong desire to obtain the control of the various lines. During 1905, for instance, the Canton-Hankow railway concession was repurchased by the Chinese government from an American company, while the Pekin Syndicate, a British concern, also sold their railway in Foo-nan to the Chinese government. Russia's action regarding Manchuria overshadowed, however, all other concerns during this period. The withdrawal of the proprietors of the Russo-Chinese agreement of 1901 has been chronicled. The Russian government had, however, no intention of abandoning its hold on Manchuria. It aimed not only at effective military control but the reservation to Russian subjects of mining, railway and commercial rights. Both the sovereignty of China and the commercial interests of other nations were menaced. This led to action by various powers. The preamble of the Anglo-Japanese treaty of the 30th of January 1902 declared the main

1 Tung Fu-lisian died in 1908. A sum of some $80,000 belonging to him, and left in the provincial treasury, was appropriated for works of public utility (see The Times, April 9th, 1910).

motives of the contracting parties to be the maintenance of the independence and territorial integrity of China and Korea, and the securing of equal opportunities in those countries for the commerce and industry of all nations, i.e., the policy of the “open door.” Protests were lodged by Great Britain, Japan, and the United States against the grant of exclusive rights to Russian subjects in Manchuria. Russia asserted her intention to respect the commercial rights of other nations, and on the 8th of April 1902 an agreement was signed at Peking which appeared to show the good faith of the Russian government, as it provided for the withdrawal of the Russian troops in Manchuria within eighteen months from that date. In accordance with this agreement the Shan-hai-kwan-Niu-chwang railway was transferred to China in October 1902 and the district between Shan-hai-kwan and the Liao river evacuated by Russia. But it soon appeared that Russia’s hold on the country had not relaxed. Advantage was taken of the terms of concession granted in August 1896 to the Russo-Chinese Bank1 to erect towns for Russian colonists and to plant garrisons along the line of railway, and to exclude Chinese jurisdiction altogether from the railway zone. The so-called evacuation became in fact the concentration of the Russian forces along the line of railway. Moreover, the maritime customs at Niu-chwang were retained by the Russo-Chinese Bank despite protests from the Chinese imperial authorities, and a Russian civil administration was established at that port. The evacuation of southern Manchuria should have taken place in April 1903, but in that month, instead of fulfilling the conditions of the 1902 agreement, the Russian charged d’affaires in Peking made a series of further demands upon China, including the virtual reservation of the commerce of Manchuria for Russian subjects. Though Russia officially denied to the British and American governments that she had made these demands, it was demonstrated that they had been made. The United States and Japan thereupon insisted that China should conclude with them commercial treaties through opening Mukden and two ports on the Yalu river to foreign trade. The American treaty was signed on the 8th of October 1903—the day fixed for the complete evacuation of Manchuria by Russia—and the Japanese treaty on the day following. Both treaties provided that the ports should be opened after ratifications had been exchanged. From fear of Russia China, however, delayed the ratification of the treaties. Meantime, in August 1903, a regular through railway service between Moscow and Port Arthur was established. In the same month a Russian Viceroyalty of the Far East was created which in effect claimed Manchuria as a Russian province. In September Russia withdrew some of the demands she had made in April, but her concessions proved illusory. When the 8th of October passed and it was seen that the Russians had not withdrawn their troops2 there issued for a time threats of war from Peking. Yuan Shih-kai, the viceroy of Chih-li, who had at his command some 65,000 troops trained by Japanese officers, pressed on the government the necessity of action. At this point Japan intervened. Her interests were directly affected by Russia’s action not only in Manchuria, but in Korea, and seeing that China was powerless the Japanese government negotiated directly with St. Petersburg. In these negotiations Russia showed that she would not yield her position in either country except to force. Japan chose the issue of war and proved successful. The Russo-Japanese War did not very greatly alter China’s position in Manchuria. In the southern part of that country Japan succeeded to the special privileges Russia had wrung from China (including the lease of Port Arthur); in the north Russia remained in possession of the railway zone. For Japan’s position as at once a legatee of special privileges and the champion of China’s territorial integrity and “the open door” see JAPAN, § History. However, the attitude of Japan was more conciliatory than that of Russia had been; Mukden and other places were thrown open to foreign trade and Chinese civil administration was re-established. The important results of the war, so far as China was concerned, were not to be looked for in Manchuria, but in the new spirit generated in the Chinese. They had been deeply humiliated by the fact that in the struggle between Russia and Japan China had been treated as a negligible quantity, and that the war had been fought on Chinese territory. The lesson which the loot of Peking and the fall of the Boxers in 1900 had taught was now thoroughly mastered; the awakening of China was complete. The war had shown that when an Eastern race adopted Western methods it was capable of defeating a European nation.

It was fortunate that among the influential advisers of the throne at this time (1905-1908) were Prince Chun (the prince who had visited Germany in 1905), Yuan Shih-kai, the viceroy of Chih-li, and Chang Chih-tung, the viceroy of Hu-kwang (i.e., the provinces of Hu-peh and Hu-nan), all men of enlightened and strong character. In 1907 both the viceroys named were summoned to Peking and made members of the grand council, of which Prince Ching, a man of moderate views, was president. Yuan Shih-kai was an open advocate of a reform of the civil service, of the abolition of Manchu privileges, of education and other matters. He had specially advocated the reconstitution of the military forces of the empire, and in Chih-li in 1905 he demonstrated before a number of foreign military attaches the high efficiency attained by the forces of the metropolitan province. The success achieved by Yuan Shih-kai in this direction incited Chang Chih-tung to follow his example, while a decree from the throne called upon the princes and nobles of China to give their sons a military education. The formerly despised military profession was thus made honourable, and with salutary effects. The imperial princes sought high commands, officers were awarded ranks and dignities comparable with those of civil servants, and the pay of the troops was increased. The new foreign drilled northern army was called upon to furnish a large proportion of a force sent under Prince Su into Mongolia—a country which had been on the point of falling into the hands of Russia, but over which, as one result of the Russo-Japanese War, China recovered control. In 1906 a step was taken towards the formation of a national army by withdrawing portions of the troops from provincial control and placing them under officers responsible to the central government, which also took over the charge of the provincial arsenals. In the years which followed further evidence was given of the earnestness and success with which the military forces were being reorganized. Less attention was given to naval affairs, but in the autumn of 1905 a commission under Tsai Hsien, a brother of the emperor Kwang-hsu, was sent to Europe to report on the steps necessary for the re-establishment of a fleet. Previously (in 1907) societies had been started in several provinces to collect funds for naval purposes. The most striking evidence of the change which had occurred was, however, the appointment (in 1905) of an Imperial Commission, headed by Prince Tsai Tse, to study the administrative systems of foreign countries with a view to the possible establishment of a representative government in China. The revolutionary nature of this proposal excited indignation among the adherents to the old order, and a bomb was thrown among the commissioners as they were preparing to leave Peking. After visiting Japan, America and Europe the commission returned to

1 This institution was nominally a private concern which financed the Manchuria railway, but it acted as part of the Russian government machinery. The existence of the contract of the 27th of August 1896 was frequently denied until expressly admitted by the Russo-Chinese agreement of the 8th of April 1902.

2 The 8th of October the Russian troops had been withdrawn from Mukden, but they reoccupied the town on the 28th of the same month, Admiral Alexieff, the viceroy of the Far East, alleging that the inertia of the Chinese officials seriously hindered the work of extending civilization in Manchuria.

3 The form of outrage, probably the first of its kind in China, was itself a symptom of the changed times. The bomb injured Prince Tsai Tse and another commissioner, and the departure of the commission was consequently delayed some months.
Peking in July 1906. A committee over which Prince Ching presided was appointed to study the commission's report, and on the 1st of September following an edict was issued in which the establishment of a parliamentary form of government was announced, at a date not fixed.

To fit the country for this new form of government (the edict went on to declare) the administration must be reformed, the laws revised, education promoted and the finances regulated. This edict, moreover, was but one of many edicts issued in 1906 and following years which showed how great a break with the past was contemplated. In November 1906 two edicts were issued with the object of reorganizing the central administrative offices. Their effect was to simplify the conduct of business, many useless posts being abolished, while an audit board was created to examine the national accounts. In November 1907 another edict was promulgated stating that for the present the formation of Houses of Lords and of Commons to determine all public questions was not practicable, but that it was proposed, as a preliminary measure, to create an Imperial Assembly. At the same time a scheme of provincial councils was ordered to be prepared. A more definite step followed in 1908 when a decree (dated the 27th of August) announced the convocation of a parliament in the ninth year from that date.

One of the changes made in the public offices brought China into conflict with Great Britain. On the 9th of May 1906 a decree appointed Chinese commissioners to control the Imperial Maritime Customs. This was the only department of the government under European (British) control, and the only department also against which no charge of inefficiency or corruption could be brought. The change decreed by China was in accord with the new national sentiment, but by all the foreign powers interested it was felt that it would be a retrograde step if the customs were taken out of the control of Sir Robert Hart (q.v.), who had been since 1863 inspector-general of the customs. The British secretary of state for foreign affairs (Sir Edward Grey) at once protested against the decree of the 6th of May, pointing out that the continuation of the established system had been stipulated for in the loan agreements of 1866 and 1868. As a result of this and other representations the Board of Control of the Customs was late in 1906 made a department of the Board of Finance. The Chinese controllers-general remained in office, and despite the assurances made to Great Britain by China (in a note of the 30th of June 1906) that the appointment of the controllers-general was not intended to interfere with the established system of administration, the absolute authority of Sir Robert Hart was weakened. Sir Robert Hart returned to England in 1908 "on leave of absence," Sir Robert Bredon, the deputy inspector-general, being placed in charge of the service under the authority of the Board of Control, of which on the 5th of April 1910 it was announced that he had been appointed a member. This step was viewed with disfavour by the British government, for, unless Sir Robert Bredon's post was to be merely a sinecure, it imposed two masters on the maritime customs. On the 20th of April Sir Robert Bredon severed his connexion with the Board of Control. At the same time Mr F. A. Aglen (the Commissioner of Customs at Hankow) became acting Inspector General (Sir Robert Hart being still nominally head of the service). The attempt on the part of the Chinese to control the customs was evidence of the strength of the "young China" or Recovery of Rights party—the party which aspired to break all the chains, such as extra-territoriality, which stamped the country as not the equal of the other great nations.

In the steps taken to suppress opium smoking evidence was forthcoming of the earnestness with which the governing body in China sought to better the condition of the people. Opium smoking, followed, in China, the introduction of tobacco smoking, and is stated to have been introduced from Java and Formosa in the early part of the 17th century. The first edict against the habit was issued in 1729. At that time the only foreign opium introduced was by the Portuguese from Goa, who exported about 200 chests a year. In 1733 English merchants in India entered into the trade, which in 1781 was taken over by the East India Company—the import in 1790 being over 4000 chests. In 1796 the importation of foreign opium was declared contraband, and between 1839 and 1860 the central government attempted, without success, to suppress the trade. It was legalized in 1838 after the second "opium war" with Great Britain. At that time the poppy was extensively grown in China, and the bulk of the opium smoked was, and continues to be, manufactured in India. But since 1860 the importation of opium from India greatly increased. Opium was also imported from Persia (chiefly to Formosa, which in 1895 passed into the possession of Japan). The total foreign import in 1863 was some 70,000 piculs, in 1879 it was 102,000 piculs, but in 1905 had fallen to 56,000 piculs. The number of opium smokers in China in the early years of the 20th century was estimated at from 25 to 30 millions. The evil effects of opium smoking were fully recognized, and Chang Chih-tung, one of the most powerful of the opponents of the habit, was high in the councils of the dowager-empress. On the 20th of September 1906 an edict was issued directing that the growth, sale and consumption of opium should cease in China within ten years, and ordering the officials to take measures to execute the imperial will. The measures promulgated, in November following, made the following provisions—

1. The cultivation of the poppy to be strictly limited annually by the central government in all the provinces; 2. all persons using opium to be registered; 3. all shops selling opium to be gradually closed, and all places where opium is smoked to discontinue the practice within six months; 4. anti-opium societies to be officially encouraged; (5) all officials were requested to set an example to the people, and all officials under sixty were required to abandon opium smoking within six months or to withdraw from the service of the state.

It was estimated that the suppression of opium smoking would entail a yearly loss of revenue of over £1,600,000, a loss about equally divided between the central and provincial governments. The first step taken to enforce the edict was the closing of the opium dens in Peking on the last day of 1906.

During 1907 the opium dens in Shanghai, Canton, Fu-chow and many other large cities were closed, and restrictions on the issue of licences were introduced in the foreign settlements; even the eunuchs of the palace were prohibited from smoking opium under severe penalties. The central government continued its campaign to suppress the use of opium, and officials were whole-hearted in carrying out the imperial regulations in other provinces—notably in Kwei-chow and in the provinces of the lower Yangtze valley.—Great suppression was exhibited in dealing with the subject of opium smoking in the Chinese army. The Peking government—the correspondent of The Times in a journey to Turkestan in the early part of 1910, found that in Shensi province the people's desire to suppress the opium trade was in advance of the views of the government. Every day trains of opium carts were passing travelling under official protection. But in the adjoining province of Shansi there had been complete

suppression of poppy cultivation and in Kansu the officials were conducting a very vigorous campaign against the growth of the poppy.  
In their endeavours to suppress opium smoking the Chinese government appealed to the Indian government for help, and in 1907 received a promise that India would decrease the production of opium by 10 per cent annually for four years and substantially if China did likewise.  
The Indian government also asserted to India opium being taxed equally with Chinese opium, but China did not raise the duty on foreign opium. In 1908 the Indian government undertook to reduce the amount of opium consumed in India to 100 chests yearly. The opium stores in Hong-Kong were closed. In February 1909, on the initiative of the United States, an international conference was held at Shanghai to consider the opium trade and habit. At this conference the Chinese representative claimed that the production of opium in China had already been reduced by one-half—a claim not borne out by the ascertained facts. The conference was unable to suggest any heroic measures, but a number of proposals were agreed to including the closing of opium dens in the forego.  

The attempts to reform the educational system of China on a comprehensive scale date from the year of the return of the court to Peking after the Boxer troubles. In 1902 regulations were sanctioned by the emperor which aimed at remodelling the methods of public instruction. These regulations provided among other things for the establishment at Peking of a university giving instruction in Western learning, a technical college, and a special department for training officials and teachers. A much more revolutionary step was taken in September 1905 when a decree appeared announcing as from the beginning of 1906 theabolition of the existing method of examinations. The new system was to include the study of modern sciences, history, geography and foreign languages, and in the higher grades political economy and civil and international law. Thousands of temples were converted to educational purposes. In Canton, in 1907, the old examination hall was demolished to make way for a college with every appliance on Western lines. Equal zeal was noticeable in such conservative cities as Si-gan-fu, and in remote provinces like Kansu. By May 1906 fifteen so-called universities had been founded. Moreover, many young Chinese went abroad to acquire education—in Japan alone in 1906 there were 15,000 students. In the sameyear primary schools for girls were established. Perhaps the most striking evidence of the new spirit regarding education was the tenour of a communication to the throne from the head of the Confucian family. On the 31st of December 1906 an imperial edict had appeared raising Confucius to the same rank as Heaven and Earth—an action taken to indicate the desire of the government to emphasize the value of ethical training. In thanking the throne for the honour conferred on his ancestor the head of the family urged that the new system be founded at the birth-place of Confucius the teaching of which should include foreign languages, physical culture, political science and military drill.  

While China, with the consent of the emperor and the empress-dowager, and under the guidance of Prince Ching, Yuan Shih-kai and Chang Chih-tung, was endeavouring to bring about internal reforms, her attitude to foreign powers was one of reserve and distrust. This was especially marked in the negotiations with Japan and with Russia concerning Manchuria, and was seen also in the negotiations with Great Britain concerning Tibet. It was not until April 1908, after four years' negotiations, that a convention with Great Britain respecting Tibet was signed, Chinese suzerain rights being respected. In September the Dalai Lama arrived in Peking from Mongolia and was received by the emperor, who also gave audience to a Nepalese mission.  

The emperor Kwang-su had witnessed, without being able to guide, the new reform movement. In August 1908 an edict was issued in his name announcing the convocation of a parliament in nine years' time. In November he died. His death occasioned no surprise, as disquieting reports about his health had been current since July, but the announcement that the dowager empress died on the 15th of November (the day after that on which the emperor was officially stated to have died) was totally unexpected. She had celebrated her birthday on the 3rd of November and appeared then to be in good health. The empress dowager had taken part in the choice of a successor to the throne, Kwang-su's valedictory edict had been drawn up under her supervision, and it is believed that the emperor died some days previous to the date officially given for his death. Kwang-su died childless and was succeeded by his infant nephew Pu-Yi (born on the 8th of February 1906), a son of Prince Chun, who was appointed regent. Prince Chün—himself then only twenty-six years old—had exercised considerable influence and power since his mission to Germany in 1900, and was one of the most enlightened of the Manchu princes. The death of the dowager empress removed a powerful obstacle to a reformed regime, and with her passed away the last representative of the old era in China.  

The accession to the throne of Pu-Yi, who was given as reigning title Hsuan Tung ("promulgating universally"), was unaccompanied by disturbances, save for an outbreak at Ngan-king, easily suppressed. Prince Chün had the support of Yuan Shih-kai and Chang Chih-tung: the two most prominent Chinese members of the government at Peking—and thus a division between the Manchus and Chinese was avoided. On the 2nd of December 1908 the young emperor was enthroned with the usual rites. On the day following another edict, which, it was stated, had had the approval of the late dowager empress, was issued, reaffirming that of the 27th of August regarding the grant of a parliametary constitution in nine years' time, and urging the people to prepare themselves for the change. Other edicts sought to strengthen the position of the regent as de facto emperor. Yuan Shih-kai and Chang Chih-tung received the title of Grand Guardians of the Heir, and the year 1908 closed with the chief Chinese members of the government working, apparently, in complete harmony with the regent.  

The 5th anniversary of 1909, however, the political situation was rudely disturbed by the dismissal from office of Yuan Shih-kai. This step led to representations by the British and American ministers to Prince Ching, the head of the foreign office, by whom assurances were given that no change of policy was contemplated by China, while the regent in a letter to President Taft reiterated the determination of his government to carry through its reform policy. The dismissal of Yuan Shih-kai was believed by the Chinese to be due to his "betrayal" of the emperor Kwang-su in the 1898 reform movement. He had nevertheless refused to go to extremes on the reactionary side, and in 1909, as governor of Shan-tung, he preserved a neutrality which greatly facilitated the relief of the Peking legations. During the last years

2 The first recorded importation of morphia into China was in 1822, and it is suggested that it was first used as an anti-opium medicine. Morphia-taking, however, became a habit in 1902 owing to the fact that morphia were imported (enough for some 900,000,000 injections). To check the evil the Chinese government during 1903 imposed a tax of about 200% ad valorem, with the result that the imports declared to the customs fell in 1905 to 54 oz. only. The profits were estimated to be a diminished demand, but by smuggling (Morse's Trade and Administration of the Chinese Empire, p. 351).  
3 A regulation by the ministry of education, dated the 14th of January 1910, ordered that no girl should be admitted to school dressed in foreign clothes or with unnatural (i.e. bound) feet.

Death of the emperor and of the dowager empress.

Accession of Hsuan Tung.

Dismissal of Yuan Shih-kai.
The efforts of the central government to increase the efficiency of the army and to re-create a navy were continued in 1910. China was credited with the intention of spending £40,000,000 on the rehabilitation of its naval and military forces. It was estimated in March 1910 that there were about 150,000 untrained men, but their independent spirit and dissatisfaction constituted a danger to internal peace. The danger was accentuated by the mutual jealousy of the central and provincial governments. The anti-dynastic agitation, moreover, again seemed to be growing in strength. In April 1910 there was serious rioting at Changsha, Hu-nan, a town whence a few years previously had issued a quantity of anti-foreign literature of a vile kind. The immediate causes of the riots seem to have been many: rumours of the intention of the foreign powers to dismember China, the establishment of foreign firms at Changsha competing with native firms and exporting rice and salt at a time when the province was suffering from famine, and the approach of Hailey's comet. Probably the famine precipitated the outbreak, which was easily crushed, as was also a rising in May at Yung chow, a town in the south of Hu-nan. Much mission and mercantile property was wrecked at Changsha, but the only loss of life was the accidental drowning of three Roman Catholic priests.

Thus in August 1910 effected considerable and unexpected changes in the composition of the government. Tang Shao-yi, a former lieutenant of Yuan Shih-kai, was appointed president of the Board of Communications, and to him fell the difficult task of reconciling Chinese and foreign interests in the development of the railway system. Sheng Kung-pao regarded as the chief Chinese authority on currency questions, and an advocate of the adoption of a gold standard, was attached to the Board of Finance to help in the reforms decreed by an edict of May of the same year (see ante, Currency). The issue of the edict was attributed to the influence with the regent of Prince Tsai-tao, who had recently returned from a tour in Europe, where he had specially studied questions of national defence. The changes made among the high officials tended greatly to strengthen the central administration. The government had viewed with some disquiet the Russo-Japanese agreement of the 4th of July concerning Manchuria (which was generally interpreted as in fact lessening the authority of China in that country), it had become involved in another dispute with Great Britain, which regarded some of the measures taken to suppress opium smoking as a violation of the terms of the Choo-Tuck treaty, and this had caused much alarm in India. Thus the appointment to high office of men of enlightenment, pledged to a reform policy, was calculated to restore confidence in the policy of the Peking authorities. This confidence would have been greater had not the changes indicated a struggle for supreme power between the regent and the dowager empress Lung Yu, widow of Kwang-su.

The strength of the various movements at work throughout China was at this time extremely difficult to gauge; the intensity of the desire for the acquisition of Western knowledge was equalled by the desire to secure the independence of the country from foreign control. The second of these desires gave the force it possessed to the anti-dynastic movement. At the same time some of the firmest supporters of reform were found among the Manchus, nor did there seem to be any reason to doubt the intention of the regent—if he retained power—to guide the nation through the troubled period of transition into an era of constitutional government and the full development of the resources of the empire.

BIBLIOGRAPHICAL NOTES. Knowledge of the ancient history of China is necessarily derived from the native writers on the subject. Fortunately, the Chinese have always regarded the preservation of the national records as a matter of supreme importance. Confucius set an example in this respect, and has preserved for us in the Spring and Autumn Annals and the Shu-ching, or Book of History, records of his country's progress during the past and then present centuries. The celebrated emperor Shih Hwang-ti, in establishing the empire, attempted to strengthen his cause by destroying all works on the national history. But so strongly was the historical sense inculcated in the people that immediately on the death of the

tyrant the nation's records were again brought to light, and have been carefully preserved and edited since that time. Prof. Legge's translation of the Spring and Autumn Annals and the Shu-king, or Book of History, in the "Sacred Books of the East" series, have opened for students the stores of historical knowledge which were at the command of Confucius, and European writers on Chinese history have found in the dynastic annals a never-failing source of valuable information. It was from these works and epitomes of those of all nationalities that the great national celebratory Histoire générale de la Chine, and it is from similar sources that all other writers on Chinese history have drawn their inspiration.

The following works on ancient and modern Chinese history may be mentioned: J. de M. de Perriers Histoire générale de la Chine (1777); J. B. du Halde, General History of China (4 vols., 1736); M. de Guignes, Voyages à Peking . . . (3 vols., 1808); D. Boulger, A History of China (3 vols., 1881); Valentine Chirn, The Far Eastern Question (1856); E. R. Huc, The Chinese Empire (4 vols., 1859); R. Backhouse, Confucius and his Religion (1856); and G. Pauthier, Histoire des relations politiques de la Chine avec les puissances occidentales depuis les temps les plus anciens jusqu'à nos jours . . . (1859); Sir George Staunton, Notes on the Proceedings and Occurrences during the British Embassy to China in 1816 (1824); Chinese Expansion historically reviewed, a paper read before the Central Asian Society by Baron Suyematsu on January 11, 1905; F. Hirth, Ancient History of China (New York, 1908); Prof. Herbert Giles's Chinese Biographical Dictionary (1897) is a storehouse of biographical detail and anecdote.

VI. CHINESE ART

1. Painting.—Painting is the pre-eminent art of China, which can boast of a succession of great painters for at least twelve centuries. Though the Chinese have an instinctive gift for harmonious colour, their painting is above all an art of line. It is intimately connected with writing, itself a fine art demanding the same skill and supple power in the wielding of the brush. The most typical expression of the Chinese genius in painting is the ink sketch, such as the masters of the Sung dynasty most preferred and the Japanese from the 15th century adopted for an abiding model. Utmost vigour of stroke was here combined with utmost delicacy of modulation. Rich colour and the use of gold are an integral part of the Buddhist pictures, though in the masterpieces of the religious painters a grand rhythm of linear design gives the fundamental character. Exquisite subdued colour is also found in the "flower and bird pieces" and still-life subjects of the Sung artists, and becomes more emphatic and variegated in the decorative artists of the Ming period.

Not to represent facts, but to suggest a poetic idea (often perfumed, so to speak, with reminiscence of some actual poem), has ever been the Chinese artist's aim. "A picture is a voiceless poem" is an old saying in China, where very frequently the artist was a literary man by profession. Oriental critics lay more stress on lofiness of sentiment and tone than on technical qualities. This idealist temper helps to explain the aversion of the Sung artists to the appearances of material solidity by means of chiaroscuro, &c., and the exclusive use of the light medium of water-colour. The Chinese express actual dislike for the representation of relief. Whoever compares the painting of Europe with that of Asia (and Chinese painting is the central type for the one continent, as Italian may claim to be for the other) must first understand this contrast of aim. The limitations of the Chinese are great, but these limitations save them from mistaking advances in science for advances in art, and from petty imitation of fact. Their religious painting has great affinity with the early religious art of Italy (e.g. that of Siena). But the ideas of the Renaissance, its scientific curiosity, its materialism, its glorification of human personality, are wholly missing in China. For Europe, Man is ever the hero and the foreground—hence the dominant study of the nude, and the tendency to thronged compositions, with dramatic motives of effort and conflict. The Chinese artists, weak in the plastic, weak in the architectural sense, paint mostly in a lyric mood, with a contemplative ideal. Hence the value given to space in their designs, the semi-religious passion for nature, and the supremacy of landscape. Beauty is found not only in pleasant prospects, but in wild solitudes, rain, snow and storm. The life of things is contemplated and portrayed for its own sake, not for its uses in the life of men. From this point of view the body of Chinese painting is much more modern in conception than that of Western art. Landscape was a mature and free art in China more than a thousand years ago, and her school of landscape is the loftiest yet known to the world. Nor was man ever dissociated from nature. As early as the 4th century Ku K'ai-chi says that in painting a certain noble character he must give him a fit background of great peaks and deep ravines. Chinese painting, in sum, finely complements rather than poorly supplements that of Europe; where the latter is strong, it is weak; but in certain chosen provinces it long ago found consummate expression for thoughts and feelings scarcely yet expressed with us. For an explanation of Chinese painting in legend, though there is no reason to doubt its great antiquity. References in Chinese literature prove that by the 3rd century a.d. it was a well-developed art. To this period is ascribed the invention of the hair-brush, in the use of which as an instrument both for writing and drawing the Chinese have attained marvellous skill; the usual material for the picture being woven silk, or, less often and since the 1st century a.d., paper. In early times wood panels were employed; and large compositions were painted on walls prepared with white lime. These mural decorations have all disappeared. History and portraiture seem to have been the prevailing subjects; a secular art corresponding to the social ideals of Confucianism. Yet long before the introduction of Buddhism (a.d. 67) with its images and pictures, we find that the two great symbolic figures of the Chinese imagination, the Tiger and the Dragon—typifying the forces of Nature and the power of the Spirit—had been evolved in art; and to imaginative minds the mystic ideas of Lao Tzü and the legends of his hermit followers proved a fruitful field for artistic motives of a kind which Buddhism was still more to enrich and multiply. Early classifications rank Buddhist and Taoist subjects together as one class.

With the 2nd century a.d. we come to individual names of artists and to the beginnings of landscape. Ku K'ai-chi (4th century) ranks as one of the greatest names of Chinese art. A painting by him now in the British Museum (Plate I. fig. 1) shows a maturity which has nothing tentative about it. The dignified and elegant types are rendered with a mastery of sensitive brush-line which is not surpassed in later art. Ku K'ai-chi painted all kinds of subjects, but excelled in portraiture. During the next century the criticism of painting was formulated in six canons by Hsêh Ho. Rhythm, organic or structural beauty, is the supreme quality insisted on.

During the T'ang dynasty the empire expanded to its utmost limits, stretching as far as the Persian Gulf. India was invaded; Buddhism, taught by numbers of Indian monks, became established and correspondingly the ideas and imaginations of the time. The vigorous style of a great era was impressed upon the T'ang art, which culminated in Wu Tao'tzü, universally acknowledged as the greatest of all Chinese painters. It is doubtful if any of his work remains. The picture reproduced (Plate I. fig. 2) was long attributed to him, but is now thought to be of later date, like the two landscapes well known under his name in Japan. Wu Tao'tzü seems to have given supreme expression to the central subject of Buddhist art, the Nirvana of Buddha, who lies serenely asleep, with all creation, from saints and kings to birds and beasts, passionately bewailing him. The composition is known from Japanese prints; and it is in fact from the early religious schools of Japan that we can best conjecture the granduer of the T'ang style. Wu Tao'tzü excelled in all subjects: other
masters are best known for some particular one. Han Kan was famous for his horses, the models for succeeding generations of painters, both Chinese and Japanese. A specimen of brush is in the British Museum; and in the same collection is a long roll which gives a glimpse of the landscape of this age. It is copied from a master of the Yuen dynasty, Chao Meng-fu, from a famous painting by Wang Wei, representing scenes on the Wang Ch'uan, the latter's home (Plate I. fig. 3 shows a fragment). With the T'ang age landscape matured, and two schools arose, one headed by Wang Wei, the other by Li Suh-hsin. The style of Wang Wei, who was equally famous as a poet, had a romantic idealist character—disdainful of mere fact—which in later developments created the "literary man's picture" of the Southern school, as opposed to the vigorous naturalism of the North.

Next come five brief dynasties, memorable less for any corporate style or tradition, than for some fine painters like Hsu Hsi, famous for his flowers, and Huang Ch'uan, a great master in a delicate style. Two pictures by him, hawks and peonies, of extraordinary beauty, are in the British Museum.

The empire, which had been broken up, was reunited, though shorn of its outer dependencies, under the house of Sung. This was an age of culture in which the individual was proclaimed anew; glorious in art as in poetry and philosophy; the period which for Asia stands in history as the Periclean age for Greece.

The religious paintings of Li Lung-mien, the grandest of Sung masters, if less forcible than those of T'ang, were unsurpassed in harmonious rhythm of design and colour. But the most characteristic painting of this period is in landscapes and nature-scapes. With the passion unatched in Europe till Wordsworth's day, the Sung artists portrayed their delight in mountains, mists, plunging torrents, the flight of the wild gese from the reed-beds, the moonlit reveries of sages in forest solitudes, the fisherman in his boat on lake or stream. In these, as in the Zen philosophy of contemplation, a flowering branch was no mere subject for a decorative study, but a symbol of the infinite life of nature. A mere hint to the spectator's imagination is often all that they rely on; proof of the singular fulness and poetry of the culture of the time. The art of suggestion has never been carried farther. Such traditional subjects as "Curfew from a Distant Temple" and "The Moon over Raging Waves" indicate the poetico-atmosphere of this art. Ma Yuan, Hsia Kuei and the emperor Hwei-ts'ie are among the greatest landscape artists of the period. They belong to the South Sung school, which loved to paint the gorges and towering rock-pinnacles of the Yangtse. The sterner, less romantic scenery of the Hwangs-Ho inspired the Northern school, of which Kuo Hsi and Li Ch'eng were famous among the earlier, and Kuo Kung of the latter part of the period. They were often treat as the greater of the two, and Chao Hui the less. They were employed as court artists, and their works are known to us through the later copy shops. The influence of the Sung school is seen in all the Eastern countries.

The Mongol dynasty continues in art the Sung tradition.

The present dynasty prolongs the history of Ming art. The literary school of the South became more prominent, sending out offsetts in Japan. There has been no movement of national life to be reflected in art, though a great depth of body of admirable painting has been produced, down (from A. D. 1644) to the present day. The four landscape masters known as "the four Wangs," Yün Shou-p'ing and Wu Li are pre-eminent names.

SOURCES AND AUTHORITIES.—While the designs on porcelain, screens, &c., have long been admired in the West, the paintings of which these are merely reproductions have been utterly ignored. Ignorant of the existence of the greatest artists of this age, a great school of Chinese painting has been denied. Materials for study are scanty. Fires, wars and the recent armed ravages of Western civilization have left but little. The profound indifference of the Chinese to foreign work has so far prevented the collections of remains from being known. The Japanese, always enthusiastic students and collectors of the continental art, claim (whether justly or not, is hard to ascertain) that the finest specimens are now in their country. Many of these are reproduced in the two Tokyo publications, the Kokka, Mr Tajima's Select Relics, &c., with Japanese criticisms in English. Of actual paintings the British Museum possesses a fair number, and the Louvre a few, of real importance.

Copied and borrowed.—

3. Architecture.—In architecture the Chinese genius has found but limited and unmemorable expression. A nation of painters has built picturesquely, but this picturesqueness has fought against the attainment of the finest architectural qualities. There has been little development; the arch, for instance, though known to the Chinese from very early times, has been scarcely used as a principle of design, and the cupola has been undiscovered or ignored; and though foreign architectural ideas were introduced under the influence of the Buddhist and Mahomedan religions, these were more or less assimilated and subordinated to the dominant Chinese design. Ruins scarcely exist and no building earlier than the 17th century A.D. is known; but we know from records that the forms of architecture still
prevalent imitate in essentials those of the 4th and 5th centuries B.C. and doubtless represent an immemorial tradition.

The grand characteristic of Chinese architecture is the prominent importance of the roof. The t'ing is the commonest model of building. The roof is the main feature; in fact the t'ing consists of this roof, massive and immense, with recurved edges, and the numerous short columns on which the roof rests. The columns are of wood, the straight stems of the nayim being specially used for this purpose. The walls are not supports, but merely fill in, with stone or brickwork, the spaces between the columns. The scheme of construction is thus curiously like that of the modern American steel-framed building, though the external form may be derived from the tent of primitive nomads. The roof, being the preponderant feature, is that on which the art of the architect has been concentrated. A double or a triple roof may be devised; the ridges and eaves may be decorated with dragons and other fantastic animals, and the eaves underlaid with carved and lacquered woodwork; the roof itself is often covered with glazed tiles of brilliant hue. In spite of efforts, sometimes desperate, to give variety and individual character by ornament and detail, the general impression is one of poverty of design. Chinese buildings are usually one-storied and are developed horizontally as they are increased in size. The principle which determines the type of symmetry is a uniformisation increases the general architectural monotonous produced by a preponderance of horizontal lines.

A special characteristic of Chinese architecture is the pai-lou, an archway erected only by special authority, usually to commemorate famous persons. The pai-lou is commonly made of wood with a tiled roof, but sometimes is built entirely of stone, as is the gateway at the avenue of the Ming tombs. A magnificent example of the pai-lou is that on the avenue leading to Wo Fo Si, the temple of the Sleeping Buddha, near Peking. This is built of marble and glazed terra-cotta. The pai-lou, like the Japanese torii, derives its origin from the torus of Indian stupas. Lotti, a temple tower called t'ai, usually square and of stone, seem to have been a common type of important building in early times. They are described in old books as erected by the ancient kings and used for various purposes. The towers of the Great Wall are of the same character, and are made of stone, with arched doors and windows. Stone, though plentiful in most provinces of the empire, has been little used by the Chinese who prefer wood or brick. M. Paleologue attributes this preference of light and destructible materials to the national indifference of the Chinese to posterity and the future, their enthusiasm being wholly devoted to their ancestors and the past.

Temples are designed on the general t'ing model. The Temple of Heaven is the most imposing of the Confucian temples, conspicuous with its covering of deep-blue tiles and its triple roof. Near this is the great Altar of Heaven, consisting of three circular terraces with marble balustrades. Buddhist temples are built on the general plan of secular residences, and consist of a series of rectangular courts with the principal building in the centre, the lesser at the sides. Lama temples differ little from these except in the interior decorations and symbolism. Mahomedan mosques are far simpler and severer in internal arrangement, but outwardly these also are in the Chinese style.

The pagoda (Chinese tao), the type of Chinese architecture most familiar to the West, probably owes its peculiar form to Buddhist influence. In the pagoda alone may be found some trace of a religious imagination such as in Europe made Gothic architecture so full and splendid an expression of the aspiring spirit. The most famous pagoda was the Porcelain Tower of Nanking, destroyed by the Taiping rebels in 1854. This was covered with slabs of faience coated with coloured glazes. The ordinary pagoda is built of brick on a stone foundation; it is octagonal with thirteen storeys.

No Chinese buildings show more beauty than some of the graceful stone bridges for which the neighbourhood of Peking has been famous for centuries.

See M. Paleologue, L'Art chinois (1885); S. W. Bushell, Chinese Art, vol. i. (1904); J. Ferguson, History of Architecture; Professor Châtalet, articles in L'Alhambra, Nos. 197, 198, (L.B.)

4. Sculpture.—Except in the casting and decoration of bronze vessels the Chinese have not obtained distinction as sculptors. They have practised sculpture in stone from an early period, but the incised reliefs of the 2nd century B.C., a number of which are figured in Professor E. Chavannes's standard work, while they display a certain spirit, lack the true plastic sense, and though the power of the Chinese draughtsmen increased rapidly under the T'ang and Sung dynasties, their work in stone showed no parallel progress. The feeling for solidity, which in Japan was a natural growth, was always somewhat exotic in China. With the impulse given to the arts by Buddhism a school of sculpture arose. The pilgrim Fa Hsien records sculpture of distinctive Chinese type in the 5th century. But Indian models dominated the art. Colossal Buddhas of stone were typical of the T'ang era. Little, however, remains of these earlier times, and such true sculpture in stone, wood or ivory may be dated from the 14th and succeeding centuries. The well-known sculptures on the arch at Chu Yung Ku an (A.D. 1345) are in Hindu style, though not without elements of breadth and strength, which seem to promise a greater development than actually took place. The colossal figures guarding the approach to the Ming tombs (15th century) show that the national taste rapidly became conventional and petrified so far as monumental sculpture was concerned, though occasional examples of decorative or portrait sculpture on a smaller scale in wood and ivory are found, which in power, grace, sincerity and restraint can rank with the work of more gifted nations. Such pieces, however, are extremely rare, and at South Kensington the ivory "Kwan-yin and Child" (274. 1853) is a solitary example. As a rule the Chinese sculptor valued his art in proportion to the technical difficulties it conquered. He thus either preferred intractable materials like jade or rock-crystal, or, if he wrought in wood, horn or ivory, sought to make his work curios or intricate rather than beautiful. There is, nevertheless, beauty of a kind in Chinese bowls of jade, and there is dignity in some of the pieces of rock-crystal, but the bulk of the carving done in wood, horn or ivory does not deserve a more serious thought from the aesthetic point of view. The few fine specimens may be referred to the earlier part of the Ming dynasty when Chinese art in general was sincere and simple. After the middle of the 15th century there set in the taste for profuse ornament which injured all subsequent Chinese sculpture.

Bronzes.—In Chinese bronzes we have a more consistent and exceptional form of plastic art, which can be traced continuously for some three thousand years. These bronzes take the form of ritual or honorific vessels, and the archaic shapes used in the service of the prehistoric religion of the country are repeated and copied with slight changes in decoration or detail to the present day.

The oldest extant specimens, chiefly derived from the sack of the Summer Palace at Peking, may be referred to the Shang and Chow dynasties (1766-255 B.C.). These ancient pieces have a certain savage monumental grandeur of design, are usually covered with a rich and thick patina of red, green and brown, and are decorated with simple patterns-scrolls, zigzag lines and a form of what is known as the Greek key-pattern symbolizing respectively waves, mountains and storm clouds. The animal forms used are those of the tao-tieh (glutton), a fabulous monster (possibly a conventionalized tiger) representing the powers of the earth, the serpent and the bull. These two last in later pieces combine to form the dragon, representing the power of the air. In the Chow dynasty libation vessels were also made in the form of a deer, a ram or a rhinoceros. These characteristics are shown in figures 9-17, Plate II. Fig. 9 is a temple vessel of a shape still in use, but which must date from before 1000 B.C. With this massive piece may be contrasted

1 La Sculpture sur pierre en Chine au temps des deux dynasties Han (Paris, 1893).
The flower-like wine vase shown in fig. 10, a favourite shape which is the prototype of some of the most graceful forms of Chinese porcelain and Japanese bronze. Its date is about 1000 B.C. The large wine vase shown in fig. 11 is some 400 years later. On the body appears the head of the tao-tieh, on the handles are superbly modelled serpents. The technique, which in the previous pieces was somewhat rude, has now become perfect, yet the menacing majestic feeling remains. We see it no less clearly in fig. 12, a marvellous vessel richly inlaid with gold and silver and covered with an emerald-green patina. It may date from about 500 B.C., and indicates that even in this remote epoch the Chinese were not only daring and powerful artists but also master-craftsmen in metal.

It is indeed at this period that the art reaches its climax. The monumental grandeur of the Shang specimens is often allied to clumsiness; the later work, if more elaborate, is always less powerful. Nevertheless, it is to a later period that ninety-nine out of a hundred Chinese bronzes must be referred, and the greatest majority belong either to the Han and succeeding dynasties (220 B.C.—A.D. 400), or to the Renaissance of the arts which culminated under the Ming dynasty a thousand years later.

The characteristics of the first of these periods is the free use of small solid figures of animals as decoration—the phoenix, the elephant, the frog, the ox, the tortoise, and occasionally men; shapes grow less austere and less significant, as a comparison between figures 11 and 13 will indicate; then towards the end of the 2nd century A.D. the influence of Buddhism is felt in the general tendency towards suavity of form (fig. 14). This vase is most delicately though sparingly inlaid with silver and a few touches of gold. Some small pieces, very richly and delicately inlaid and covered with a magnificent emerald-green patina, belonging to this period, form a connecting link between the inlaid work of the Chow dynasty and that of the Sung and Ming dynasties. The mirrors with Graeco-Bactrian designs, a conclusive proof of the external influences brought to bear upon China, are of this period. The chief interest is in the art of the vase, the vessel.

The troubled period between A.D. 400 and A.D. 690, in spite of the interval of activity under the T'ang dynasty, produced, it would seem, but few bronzes, and those few were of no distinct or note-worthy style. Under the Sung dynasty the arts revived, and at this time some of the most splendid specimens of inlaid work belong—pieces of workmanship and taste no less perfect than that of the Japanese, in which the gold and silver of the earlier work are occasionally replaced by emeralds and jade. The vase of Kukai, the founder of the Ch'ao-shan temple (8th century), is a most beautiful example. The vessel which bore the name of Kubilai Khan and the Yuen dynasty (1280-1367) once more brought the East into contact with the West, and to this time we may assign certain fine pieces of Persian form such as pilgrim bottles. The very formalized Ararat type, which first appeared under the Ming dynasty (1368-1644), with which the modern history of Chinese art seems to end.

The work done while the Ming dynasty was still young provides the student of Chinese art with many problems, and in one or two cases even the South Kensington authorities assign to pre-Christian times pieces that are clearly Ming workmanship. The tendency of the period was eclectic and archaistic. The products of earlier days were reproduced with perfect technical command of materials, and with admirable taste; it is indeed by an excess of these qualities that archaistic Ming work may be distinguished from the true archaic. In fig. 15 we see how the Ming bronze worker took an earlier Buddhist form of vase and gave it a new grace that amounted almost to artifice. A parallel might be found among the products of the so-called 'Parthian style' of Egyptian and Etruscan bronzes. The introduction of the elephant, which is a feature of early Chinese bronze art, and the transition from the real to the ideal are handled so much as to rob the design of the old majestic vigour and to make it as the splendid effort of an age of culture, and not the natural product of a period of strength.

The Chinese attitude to the difference tells most clearly. Here we find the monstrous forms of the Shang and Chow dynasties revived by men who appreciated their spirit but could not help making the revival an excuse for the display of their own contemporaries. The monstrous vases and incense-burners of the past thus appear once more, but are now decorated with a delicate embroidery of inlay, are polished and finished to perfection, but lose therewith just the rudeness of edge and outline which made the older works so strikingly significant. At times even some grandly planned vessel will appear with such a festoon of pretty tracery wrought about it that the incongruity is little short of ridiculous, and we recognize we have passed the turning-point to decline.

Decline indeed came rapidly, and to the latter part of the Ming epoch we must assign those countless bronzes where dragons and flowers and the stock symbols of happiness, good luck and longevity sprawl together in interminable convolutions. When once we reach this stage of contortion, of elaborate and piercing relief work, we come to place in history of Chinese bronzes where serious study may cease, except in so far as the study of the symbols themselves throws light upon the history of Chinese proclain (see Ceramics). One class of bronze alone needs a word of notice, namely, the profusely decorated and less obviously Chinese vessels called 'lacquer' and ostensibly of the earlier age, and that neither the added delicacy of texture and substance nor the vastly increased dexterity of workmanship can compensate for the vanished majesty. (C. J. H.)

VII. THE CHINESE LANGUAGE

Colloquial.—In treating of Chinese, it will be found convenient to distinguish, broadly, the spoken from the written language and to deal with each separately. This is a distinction which would be out of place if we had to do with any European, or indeed most Oriental languages. Writing, in its origin, is merely a symbolic representation of speech. But in Chinese, as we shall see, four sounds which have a Thibetan or Indian origin, and are obviously no older than the end of the Ming period. Of these fig. 17 will serve as a specimen, and a comparison with fig. 9 will show how the softer rounded forms and jewelled festoons of Hindu-Greek taste enervated the primitive art of the earlier age, and that neither the added delicacy of texture and substance nor the vastly increased dexterity of workmanship can compensate for the vanished majesty. (C. J. H.)
these reasons, all examples of phraseology in this article will be given in Pekingese.

So far, stress has been laid chiefly on the dissimilarity of the dialects. On the other hand, it must be remembered that they proceed from the same parent stem, are spoken by members of the same race, and are united by the bond of writing which is the common possession of all, and cannot be regarded as derived from one more than from another. They also share alike in the two most salient features of Chinese as a whole: (1) they are all monosyllabic, that is, each individual word consists of only one syllable; and (2) they are strikingly poor in vocables, or separate sounds for the conveyance of speech. The number of these vocables varies from between 600 and 900 in Cantonese to no more than 450 in the vernacular of Peking. This scanty number, however, is exuded by interposing an aspirate between certain initial consonants and the vowel, so that for instance *pi* is distinguished from *pu*. The latter is pronounced with little or no emission of breath, the "p" approximating the farther north one goes (e.g., at Niuchwang) more closely to a "b." The aspirated *p* is pronounced more like our interjection "Pooh!" To the Chinese ear, the difference between the two is very marked. It will be found, as a rule, that an Englishman imparts a slight aspirate to his *p*’s, *t*’s, *k*’s and *ch*’s, and therefore has greater difficulty with the unaspirated sounds in Chinese. The aspirates are better learned by the ear than by the eye, but in one way or another it is essential that they be mastered by any one who wishes to make himself intelligible to the native.

The influence of the Mongolian population, assisted by the progress of time, has slowly but surely diminished the number of vocables in Pekingese. Thus the *is* and *k* when followed by the vowel *i* (with its continental value) have gradually become softer and more assimilated to each other, and are now all pronounced *ch*. Again, all consonantal endings in *t* and *k*, such as survive in Cantonese and other dialects, have entirely disappeared from Pekingese, and *n* and *ng* are the only final consonants remaining. Vowel sounds, on the other hand, have been proportionately developed, such compounds as *so*, *sa*, *tse*, *tsa* occurring with especial frequency. (It must be understood, of course, that the above are only equivalents, not in all cases very exact, for the sounds of a non-alphabetic language.)

An immediate consequence of this paucity of vocables is that one and the same sound has to do duty for different words. Reckoning the number of words that an educated man would want to use in conversation at something over four thousand, it is obvious that there will be an average of ten meanings to each sound employed. Some sounds may have fewer meanings attached to them, but others will have many more. Thus the following represent only a fraction of the total number of words pronounced *shih* (something like the "sh" in shirt): 史 "history," 己 "to employ," 居 "a corpse," 市 "a market," 師 "an army," 頭 "a lion," 聖 "to rely on," 侍 "to wait on," 侍 "a poet," 時 "time," 瞻 "to know," 施 "to bestow," 是 "to be," 實 "solid," 失 "to lose," 示 "to proclaim," 瞻 "to look at," 十 "ten," 拾 "to pick up," 石 "stone," 世 "generation," 食 "to eat," 室 "a house," 氏 "a clan," 始 "beginning," 釋 "to set free," 試 "to test," 事 "affair," 勢 "power," 士 "officer," 警 "to swear," 避 "to pass away," 通 "to happen." It would be manifestly impossible to speak without ambiguity, or indeed to make oneself intelligible at all, unless there were some means of supplementing this deficiency of sounds. As a matter of fact, several devices are employed through the combination of which confusion is avoided. One of these devices is the coupling of words in pairs in order to express a single idea. There is a word 哥 which means "elder brother." But in speaking, the sound 哥 alone would not always be easily understood in this sense. One must either re duplicate it and say 哥哥, or prefix 大 (ta, "great") and say 大哥. Simple reduplication is mostly confined to family appellations and such adverbial phrases as 慢慢 man-man, "slowly." But there is a much larger class of pairs, in which each of the two components has the same meaning.

Examples are: 恐怕 k’ung-p’aa, "to be afraid," 告訴 kao-su, "to tell," 鐵木 shu-mu, "tree," 皮膚 *pi-fu*, "skin," 漢語 man-yng, "full," 孤立 ku-tu, "solitary." Sometimes the two parts are not exactly synonymous, but together make up the sense required. Thus in 氣息 i-shiang, "clothes," 代 more particularly clothes worn on the upper part of the body, and 王城 those on the lower part. 習鳳 feng-huang is the name of a fabulous bird, feng being the male, and huang the female. In another very large class of expressions, the first word serves to limit and determine the special meaning of the second: 果皮 "milk-skin," "cream"; 火腿 "fire-leg," "ham"; 灯籠 "lamp-cage," "lantern"; 海燕 "sea-sea," "strait." There are, besides, a number of phrases which are harder to classify. Thus, 虎 k’u means "tiger." But in any case where ambiguity might arise, 老虎, "old tiger," is used instead of the monosyllabic. 牛 (another k’u) is "fox," and 猪 li, an animal belonging to the smaller cat tribe. Together, 豚-li, they form the usual term for fox. 知 chih tao is literally "to know the way," but has come to be used simply for the verb "to know." These pairs or two-word phrases are of such frequent occurrence, that the Chinese spoken language might almost be described as bisyllabic. Something similar is seen in the extensive use of suffixes or clitics, attached to many of the commonest nouns. 女 is the word for "girl," but in speech 女子 ni-i or 女兒 i-i-i is the form used. 子 and 兒 both mean child, and must originally have been diminutives. A fairly close parallel is afforded by the German suffix chen, as in Mädchchen. The suffix 兒, it may be remarked, belongs especially to the Peking vernacular. Then, the use of so-called numeratives will often give some sort of clue as to the class of objects in which a substantive may be found. When in pidgin English we speak of "one piece man" or "three piece dollar," the word piece is simply a Chinese numerative in English dress. Even in ordinary English, people do not say "four cattle," but "four head of cattle." But in Chinese the use of numeratives is quite a distinctive feature of the language. The commonest of them, 如, can be used indifferently in connexion with almost any class of things, animal, vegetable or mineral. But there are other numeratives—at least 20 or 30 in everyday use—which are strictly reserved for limited classes of things with specific attributes. 枚 mei, for instance, is the numerative of circular objects such as coins and rings; 顆 k’o of small globular objects—pears, grains of rice, &c.; 位 k’ou classifies things which have a mouth—bags, boxes and so forth; 件 chien is used of all kinds of affairs; 支 chang of chairs and sheets of paper; 個 chih (literally half a pair) is the numerative for various animals, parts of the body, articles of clothing and ships; 把 po for things which are grasped by a handle, such as fans and knives.

This by no means exhausts the list of devices by which the difficulties of a monosyllabic language are successfully overcome. Mention need only be made, however, of the system of "tones," which, as the most curious and important of all, has been kept for the last.

The tones may be defined as regular modulations of the voice by means of which different inflections can be imparted to the same sound. They may be compared with the half-involuntary modulations which express emotional feeling in our words. To the foreign ear, a Chinese sentence spoken slowly with the tones clearly brought out has a certain sing-song effect. If we speak of the tones as a "device" adopted in order to increase the number of sounds, this must be understood rather as a convenient way of explaining their practical function than as a scientific account of their origin. It is absurd to suppose the tones were deliberately invented in order to fit each written character with a separate sound. A tone may be said to be as much an integral part of the word to which it belongs as the sound itself; like the sound, too, it is not fixed once and for all, but is in a constant, though very gradual, state of evolution. This fact is proved by the great differences of
intonation in the dialects. Theoretically, four tones have been distinguished—the even, the rising, the sinking and the entering tones. The last falls again into an upper and a lower series. But only the Cantonese dialect possesses all these eight varieties of tone (to which a ninth has been added), while Pekingese, with which we are especially concerned here, has no more than four: the even upper, the even lower, the rising and the sinking. The history of the tones has yet to be written, but it appears that down to the 3rd century B.C. the only tones distinguished were the 平 “even,” 上 “rising” and 入 “entering.” Between that date and the 4th century A.D. the 入 sinking tone was developed. In the 11th century the even tone was divided into upper and lower, and a little later the entering tone finally disappeared from Pekingese. The following monosyllabic dialogue gives a very fair idea of the quality of the four Pekingese tones—1st tone: Dead (spoken in a raised monotone, with slightly pliantive inflection); 2nd tone: Dead? (simple query); 3rd tone: Dead? (an incredulous query long drawn out); 4th tone: Dead! (a sharp and decisive answer). The native learns the tones unconsciously and by ear alone. For centuries their existence was unsuspected, the first systematic classification of them being associated with the name of Shên Yo, a scholar who lived a.d. 441-513. The Emperor Wu Ti was inclined to be sceptical, and one day said to him: “Come, tell me, what are these famous four tunes?” They are 天子圣哲 whatever your Majesty pleases to make them,” replied Shên Yo, skillfully selecting for his answer four words which illustrated, and in the usual order, the four tones in question. Although no native is ever taught the tones separately, they are none the less present in the words he utters, and must be acquired consciously or unconsciously by any European who wishes to be understood. It is a mistake, however, to imagine that every single word in a sentence must necessarily be given its full tonic force. Quite a number of words, such as the enclitics mentioned above, are not intonated at all. In others the degree of emphasis depends partly on the tone itself, partly on its position in the sentence. In Pekingese the 3rd tone (which is really the second in the ordinary series, the 1st being subdivided into upper and lower) is particularly important, and next to it in this respect comes the 2nd (that is, the lower even, or 2nd division of the 1st). It may be said, roughly, that any speaker whose second and third tones are “correct,” can, with any rate be understood, even if the 1st and 4th are slurred over.

It is chiefly, however, on its marvellous script and the rich treasures of its literature that the Chinese language depends for its unique fascination and charm. If we take a page of printed Chinese or carefully written manuscript and compare it with a page, say, of Arabic or Sanskrit, the Chinese is seen at once to possess a marked characteristic of its own. It consists of a number of wholly independent units, each of which would fit into a small square, and is called a character. These characters are arranged in columns, beginning on the right-hand side of the page and running from top to bottom. They are words, inasmuch as they stand for articulate sounds expressing root-ideas, but they are unlike our words in that they are not composed of alphabetical elements or letters. Clearly, if each character were a distinct and arbitrarily constructed symbol, only those gifted with exceptional powers of memory could ever hope to read or write with fluency. This, however, is far from being the case. If we go to work synthetically and first see how the language is built up, it will soon appear that most Chinese characters are susceptible of some kind of analysis. We may accept as substantially true the account of native writers who tell us that means of communication other than oral began with the use of knotted cords, similar to the quipus of ancient Mexico and Peru, and that these were displaced later on by the practice of notching or scoring rude marks on wood, bamboo and stone. It is beyond question that the first four numerals, as written with simple horizontal strokes, date from this early period. Notching, however, carries us but a little way on the road to a system of writing, which in China, as elsewhere, must have sprung originally from pictures. In Chinese writing, especially, the indications of such an origin are unmistakable, a few characters, indeed, even in their present form, being perfectly recognisable as pictures of objects pure and simple. Thus, for “sun” the ancient Chinese drew a circle with a dot in it; for “moon” the 4th, now 月, for “God” they drew the anthropomorphic figure 彳, which in its modern form appears as 天; for “mountains” the 3rd, now 山, for “child” 彳, now 子; for “fish” 輷, now 魚; for “mouth” a round hole, now 口; for “hand” 彳, now 手; for “well” 彳, now written without the dot. Hence we see that while the origin of all writing is pictographic, in Chinese alone of living languages certain pictures have survived, and still denote what they had denoted in the beginning. In the script of other countries they were gradually transformed into hieroglyphic symbols, after which they either disappeared altogether or became further conventionalized into the letters of an alphabet. These picture-characters, then, accumulated little by little, until they comprised all the common objects which could be easily and rapidly delineated—sun, moon, stars, various animals, certain parts of the body, trees, grass and so forth, to the number of two or three hundred. The next step was to a few compound pictograms which would naturally suggest themselves to primitive man: 月 the sun just above the horizon = “dawn”; 林 trees side by side = “a forest”; 人 a mouth with something solid coming out of it = “the tongue”; 言 a mouth with vapor or breath coming out of it = “words.”

But a purely pictographic script has its limitations. The more complex natural objects hardly come within its scope; still less the whole body of abstract ideas. While writing was still in its infancy, it must have occurred to the Chinese to join together two or more pictorial characters in order that their association might suggest the mind some third thing or idea. “Sun” and “moon” combined in this way make the character 明, which means “bright”; woman and child make 女 “good”; “fields” and “strength” (that is, labour in the fields) produce the character 男 “male”; two “men” on “earth” 坐 signifies “to sit”—before chairs were known; the “sun” seen through “trees” 景 designates the east; 家 has been explained as (1) a “pig” under a “roof,” the Chinese idea, common to the Irish peasant, of home, and also (2) as “several persons” under a “roof.” In the same sense; a “woman” under a “roof” makes the character 烏 “peace”; “words” and “tongue” 話 naturally suggest “speech”; two hands (友, in the old form 友) indicate friendship; “woman” and “birth” 娘 “born of a woman,” means “clan-name,” showing that the ancient Chinese traced through the mother and not through the father. Interesting and ingenious as many of these combinations are, it is clear that their number, too, must in any practical system of writing be severely limited. Hence it is not surprising that this class of characters, correctly called ideograms, as representing ideas and not objects, should be a comparatively small one. Up to this point there seemed to be but little chance of the written language reaching a free field for expansion. It had run so far on lines sharply distinct from those of ordinary speech, that there was nothing in the character 彼 which gave the slightest clue to the sound of the word it represented. Each character, therefore, had to be learned and recognized by a separate effort of memory. The first step in a new, and, as it ultimately proved, the right direction, was the borrowing of a character already in use in the picture to represent another word identical in sound, though different in meaning. Owing to the scarcity of vocables noted above, there might be as many as ten different words in common use, each pronounced 師. Out of those ten only one, we will suppose, had a character assigned to it—namely 方 “square” (originally said to be a

Suggestive compounds.

Phonetic characters.
picture of two boats joined together). But among the other nine was 仗, meaning "street" or "locality," in such common use that it became necessary to have some means of writing it. Instead of inventing an altogether new character, as they might have done, the Chinese took 方 "square" and used it also in the sense of "locality." This was a simple expedient, no doubt, but one that, applied on a large scale, could not but lead to confusion. The corresponding difficulty which presented itself in speech was overcome, as we saw, by many devices, one of which consisted in prefixing to the word in question another which served to determine its special meaning. A native does not say 仗 simply when he wishes to speak of a place, but "ti-fang" "earth-place." Exactly the same device was now adopted in writing the character. To 仗 "square" was added another part meaning "earth," in order to show that the 仗 in question had to do with location on the earth's surface. The whole character thus appeared as 位. Once this phonetic principle had been introduced, all was smooth sailing, and writing progressed by leaps and bounds. Nothing was easier now than to provide signs for the other words pronounced 仗. "A room" is 蓋 door-仗; "to spin" is 蓋 silk-仗; "fragrant" is 蓋 herbs-仗; "to inquire" is 蓋 words-仗; "an embankment," and hence "to guard against," is 蓇 mound-仗; "to hinder" was 蓇 woman-仗. This last example may seem a little strange until we remember that man must have played the principal part in the development of writing, and that from the masculine point of view there is something essentially obstructive and unmanageable in woman's nature. It may be remarked, by the way, that the element "woman" is often the determinative in characters that stand for unamiable qualities, e.g. 妓 "jealous," 妓 "treacherous," 妓 "false," and 妓 "uncanny." This class of characters, which constitutes at least nine-tenths of the language, has received the convenient name of phonograms. It must be added that the formation of the phonogram or phonetic compound did not always proceed along such simple lines as in the examples given above, where both parts are pictorial characters, one, the phonetic, representing the sound, and the other, commonly known as the "radical," giving a clue to the sense. In the first place, most of the phonetics now existing are not simple pictograms, but themselves more or less complex characters made up in a variety of ways. On analysing, for instance, the word 達 位 "to withdraw," we find it is composed of the phonetic 位 combined with the radical 位, an abbreviated form of 位 "to walk." But 位 sun means "grandson," and is itself a suggestive compound made up of the two characters 子 "a son" and 系 "connect." The former character is a simple pictogram, but the latter is again resolvable into the two elements 木 "a downstroke to the left" and 系 "a strand of silk," which is here understood to be the radical and appears in its ancient form as 位, a picture of cocoons spun by the silkworm. Again, the sound in most cases given by no means exactly by the so-called phonetic, a fact chiefly due to the pronunciation having undergone changes which the written character was incapable of recording. Thus, we have just seen that the phonetic of 達 is not 位 但 but sun. There are extreme cases in which a phonetic provides hardly any clue at all as to the sound of its derivatives. The character 位, for example, which by itself is pronounced 位, appears in combination as the modern phonetic 位 k'٠n, 位 juan, 蓇 yin and 蓇 chi; though in the last instance it was not originally the phonetic but the radical of a character which was analysed as 蓇 chi, "to emit breath," from 口 "the mouth," the whole character being a suggestive compound rather than an illustration of radical and phonetic combined. In general, however, it may be said that the "final" or rhyme is pretty accurately indicated, while in not a few cases the phonetic does give the exact sound for all its derivatives. Thus, the characters in which the element 子 enters are pronounced 位, 位, 位, 位, and 位; but 位 and its derivatives are all 位. A considerable number of phonetics are nearly or entirely obsolete as separate characters, although their family of derivatives may be a very large one. 位, for instance, is never seen by itself, yet 位, 位, and 位 are among the most important characters in the language. Objections have been raised in some quarters to this account of the phonetic development of Chinese. It is argued that the primitives and sub-primitives, whereby is meant any character which is capable of entering into combination with another, have really had some influence on the meaning, and do not merely possess a phonetic value. But insufficient evidence has hitherto been advanced in support of this view.

The whole body of Chinese characters, then, may conveniently be divided up, for philological purposes, into pictograms, ideograms and phonograms. The first are pictures of objects, the second are composite symbols standing for abstract ideas, the third are compound characters of which the more important element simply represents a spoken sound. Of course, in a strict sense, even the first two classes do not directly represent either objects or ideas, but rather stand for sounds by which these objects and ideas have previously been expressed. It may, in fact, be said that Chinese characters are "nothing but a number of more or less ingenious devices for suggesting spoken words to a reader." This definition exposes the inaccuracy of the popular notion that Chinese is a language of ideographs, a mistake which early translators and compilers of the Oxford English Dictionary have not avoided. Considering that all the earliest characters are pictorial, and that the vast majority of the remainder are constructed on phonetic principles, it is absurd to speak of Chinese characters as "symbolizing the idea of a thing, without expressing the name of it."

The Chinese themselves have always been diligent students of their written language, and at a very early date (probably many centuries B.C.) evolved a sixfold classification of characters, the so-called 六書 liu shu, very inaccurately translated by the Six Scripts, which may be briefly noticed:

1. 指事 chih shih, indicative or self-explanatory characters. This is a very small class, including only the simplest numerals and a few others such as 上 "above" and 下 "below."
2. 象形 hsiang hsing, pictographic characters.
3. 形聲 hsing sheng or 形聲 hsish sheng, phonetic compounds.
4. 會意 hui i, suggestive compounds based on a natural association of ideas. To this class alone can the term "ideographs" be properly applied.
5. 轉注 chuan chu. The meaning of this name has been much disputed, some saying that it means "turned round;" e.g. 成 "eye" is now written 目. Others understand it as comprising a few groups of characters nearly related in sense, each character consisting of an element common to the group, together with a specific and detachable part; e.g. 老, 考, and 孝, all of which have the meaning "old." This class may be ignored altogether, seeing that it is concerned not with the origin of characters but only with peculiarities in their use.
6. 假借 chja chieh, borrowed characters, as explained above, that is, characters adopted for different words simply because of the identity of sound.

The order of this native classification is not to be taken as in any sense chronological. Roughly, it may be said that the development of writing followed the course previously traced, that is, beginning with indicative signs, and going on with phonograms and ideograms, until finally the discovery of the phonetic principle did away with all necessity for other devices in enlarging the written language. But we have no direct evidence that this was so. There can be little doubt that phonetic compounds made their appearance at a very early date, probably prior to the invention of a large number of suggestive compounds, and perhaps even before the whole existing stock of pictograms had been fashioned. It is significant that numerous words of daily occurrence, which must have had a place in the earliest
Handbook of Chinese writing. In the very earliest inscriptions that have come down to us, the so-called "tadpole" is frequently written as 斗, without the part meaning "insect" or "reptile.

The early Chinese characters are found on bronzes dating from the late-third millennium and inscriptions on bone and tortoise shells dating from the late-fifth millennium. These inscriptions, which are known as oracle bone inscriptions, were used in the Chou dynasty for divination. The characters were written with a bone or tortoise shell, and the diviner would write a question on the shell or bone and then break it. The pieces of the shell or bone would then be thrown on the ground, and the diviner would interpret the pattern formed by the pieces. This procedure was used to predict the future or to answer questions.

The earliest form of writing in China, before the invention of the brush, was the use of stylized Drawing of a human figure. This style of writing was used for divination and for recording important events. The characters were written with a bone or tortoise shell, and the diviner would write a question on the shell or bone and then break it. The pieces of the shell or bone would then be thrown on the ground, and the diviner would interpret the pattern formed by the pieces. This procedure was used to predict the future or to answer questions.

The invention of the brush greatly improved the speed and efficiency of writing. The brush allowed for more expressive and legible writing, and it also allowed for the development of new styles and techniques. The brush was used to create calligraphy, which is a form of writing that is appreciated for its aesthetic qualities.

The development of paper also played a significant role in the development of writing. Paper was invented in China in the first century BCE, and it quickly became the preferred medium for writing. The invention of paper allowed for the mass production of books and other written materials, which greatly expanded the reach and influence of written language.

The development of printing further transformed the role of writing in society. The printing press was invented in China in the 11th century, and it was later introduced to Europe in the 15th century. The printing press allowed for the mass production of written materials, which greatly increased the accessibility of knowledge.

The evolution of written language has had a profound impact on human history. Writing has allowed for the preservation of knowledge and the transmission of ideas across generations. It has also played a key role in the development of civilization, as it has enabled the recording of laws, the keeping of accounts, and the creation of art and literature.
two indispensable aids—a dictionary and a grammar. The Chinese have found no difficulty in producing the former (see Literature). Now what is to the grammar? He might reasonably expect a people so industrious in the cultivation of their language to have evolved some system of grammar which to a certain degree would help to smooth his path. And yet the contrary is the case. No set of rules governing the mutual relations of words has ever been formulated by the Chinese, apparently because the need of such rules has never been felt. The most that native writers have done is to draw a distinction between 实字 and 虚字 “full” and “empty words,” respectively, the former being subdivided into 他字 “living words” or verbs, and 死字 “dead words” or noun-substantives. By “empty words” particles are meant, though sometimes the expression is loosely applied to abstract terms, including verbs. The above meagre classification is their nearest approach to a conception of grammar in our sense. This in itself does not prove that a Chinese grammar is impossible, nor that, if constructed, it might not be helpful to the student. As a matter of fact, several attempts have been made by foreigners to deduce a grammatical system which should prove as rigid and binding as those of Western languages, though it cannot be said that any as yet has stood the test of time or criticism. Other writers have gone to the other extreme, and maintained that Chinese has no grammar at all. In this dictum, exaggerated as it sounds, there is a very substantial amount of truth. Every Chinese character is an indivisible unit, representing a sound and standing for a root-idea. Being free from inflection or agglutination of any kind, it is incapable of indicating in itself either gender, number or case, voice, mood, tense or person. Of European languages, English stands nearest to Chinese in this respect, and whence it follows that the construction of a hybrid jargon like pidgin English presents fewer difficulties than would be the case, for instance, with pidgin German. For pidgin English simply consists in taking English words and treating them like Chinese characters, that is, dividing them of all troublesome inflections and reducing them to a set of root-ideas arranged in logical sequence. “You wantsee my no wantsee” is nothing more nor less than literally rendered Chinese: 你要我不要 “Do you want me or not?” But we may go further, and say that no Chinese character can be definitely regarded as being any particular part of speech or possessing any particular function absolutely, apart from the general tenor of its context. Thus, taken singly, the character 上 conveys only the general idea “above” as opposed to “below.” According to its place in the sentence and the requirements of common sense, it may be a noun meaning “upper person” (that is, a ruler); an adjectival meaning “upper,” “topmost” or “best”; an adverb meaning “above”; a preposition meaning “upon”; and finally a verb meaning “to mount upon,” or “to go to.” 入 is a character that may usually be translated “to enter” as in 入门 “to enter a door”; yet in the locution 入木 “enter wood,” the verb becomes causative, and the meaning is “to put into a coffin.” It would puzzle grammarians to determine the precise grammatical function of any of the words in the following sentence, with the exception of 何 (an interrogative, by the way, which here happens to mean “why” but in other contexts is equivalent to "how", "which" or "what"): 事何必古 “Affair why must ancient,” or in more idiomatic English, “Why necessarily stick to the ways of the ancients in such matters?” Or take a proverbial saying like 少見多所怪, which may be correctly rendered “The less a man has seen, the more he has to wonder at.” It is one thing, however, to translate it correctly, and another to explain how this translation can be inferred from the individual words, of which the bald equivalents might be given as: “Few what see, many what strange.” To say that “strange” is the literal equivalent of 怪 does not mean that 怪 can be definitely classed as an adjective. On the other hand, it would be dangerous even to assert that the word here plays the part of an active verb, because it would be equally permissible to translate the above “Many things are strange to one who has seen but little.”

Chinese grammar, then, so far as it deals with the classification of separate words, may well be given up as a bad job. But there still remains the art of syntax, the due arrangement of words to form sentences according to certain established rules. Here, at any rate, there is an element of something like firm ground; and for many years the dictum that “the whole of Chinese grammar depends upon position” was regarded as a golden key to the written language of China. It is perfectly true that there are certain positions and collocations of words which tend to recur, and when one sits down to formulate a set of hard-and-fast rules governing these positions, it is soon found to be a thankless task, for the number of qualifications and exceptions which will have to be added is so great as to render the rule itself valueless. 馬上 means “on a horse,” 马上 “to get on a horse.” But it will not do to say that a preposition becomes a verb when placed before the substantive, as many other prepositions come before and not after the words they govern. If we meet such a phrase as 理冠 literally “warn rebels,” we must not mentally label 理 as a verb and 理 as a substantive, and say to ourselves that in Chinese the verb is followed immediately by its object. Otherwise, we might be tempted to translate, “to warn the rebels,” whereas a little reflection would show us that the conjunction of “warn” and “rebels” has as it were two independent meanings, and that the application of common sense would indicate that there was no reason why Chinese sentences should not be dissected, by those who take pleasure in such operations, into subject, copula and predicate, but it is hardly likely that a reader of Thucydidcs and Livy, who could not possibly be induced to reproduce in writing the bisyllabic compounds of common speech. Chien “to see,” in its written form 見, could not possibly be confused with any other chien, and it was therefore unnecessary to go to the trouble of writing 看 見 k'an-chien “look-see,” as in colloquial. There was a wonderful outburst of literary activity in the Confucian era, when it would seem that the older and more cumbersome form of Seal character was still in vogue. If the mere manual labour of writing was so great, we cannot wonder that all superfluous particles or other words that could be dispensed with were ruthlessly cut away. So it came about that all the old classical works were composed in the tersest of language, and remote as it can be imagined from the lucid and flowing style of prose which has been the natural expression of the present generation. The stiffness and formal stiffness was pushed to an extreme, and resulted more often than not in the obscurity that detailed commentaries on the classics were found to be necessary, and have always constituted an important branch of Chinese literature. After the introduction of the improved style of script, and when the mechanical means of writing had been simplified, it may be supposed that literary diction also became freer and more expansive. This did happen to some extent, but the classics were held in such veneration as to exercise the profoundest influence over all succeeding schools of writers, and the divorce between literature and popular speech became permanent and irremediable. The book language
absorbed all the interest and energy of scholars, and it was inevitable that this elevation of the written should be accompanied by a corresponding degradation of the spoken word. This must largely account for the somewhat remarkable fact that the art of oratory and public speaking has never been deemed worthy of cultivation in China, while the comparatively low position occupied by the drama may also be referred to the same cause. At the same time, the term “book language,” in its widest sense, covers a multitude of styles, some of which differ from each other nearly as much as from ordinary speech. The department of fiction (see Literature), which the lettered Chinese man affects to despise and will not readily admit within the charmed circle of “literature,” really constitutes a bridge spanning the gulf between the severer classical style and the colloquial; while an elegant terseness characterizes the highest-class novel, there are others in which the style is loose and shambling. Still, it remains true that no book of any first-rate literary pretensions would be easily intelligible to any class of Chinese men, educated or otherwise, if read aloud exactly as printed. The public reader of stories is obliged to translate, so to speak, into the colloquial of his audience as he goes along. There is no inexpressibly fine quality in the everyday language that should not be rendered into characters, as is done in foreign handbooks for teaching elementary Chinese; one can only say that the Chinese do not think it worth while. There are a few words, indeed, which, though common enough in the mouths of gentle and vulgar alike, have positively no characters to represent them. On the other hand, there is a vast store of purely book words which would never be used or understood in conversation.

The book language is not only nice in its choice of words, it also has to obey special rules of construction. Of these, perhaps the most apparent is the carefully marked antithesis between characters in different clauses of a sentence, which results in a kind of parallelism or rhythmic balance. This parallelism is a noticeable feature of ordinary poetical composition, and may be well illustrated by the following four-line stanza:

“白日依山盡 The bright sun completes its course behind the mountains；黃河入海流 The yellow river flows away into the sea. 欲窮千里目 Would you command a prospect of a thousand li? 更上一層樓 Climb yet one higher.”

In the first line of this piece, every single character is balanced by a corresponding one in the second: 日 white by 黃 yellow, 日 sun by 河 river, and so on. In the 3rd and 4th lines, where more laxity is generally allowed, every word again has its counterpart, with the sole exception of 欲 “wish” and 更 “further.”

The question is often asked: What sort of instrument is Chinese for the expression of thought? As a medium for the conveyance of historical facts, subtle emotions or abstruse philosophical conceptions, can it compare with the languages of the Western world? The answers given to this question have varied considerably. But it is noteworthy that those who most deprecate the qualities of Chinese are, generally speaking, theorists rather than persons possessing a profound first-hand knowledge of the language itself. Such writers argue that want of inflection in the characters must tend to make Chinese hard and inelastic, and therefore incapable of bringing out the finer shades of thought and emotion. Answering one a priori argument with another, one might fairly retort that, if anything, flexibility is the precise quality to be predicated of a language in which any character may, according to the requirements of the context, be interpreted either as noun, verb or adjective. But all such reasoning is somewhat futile. It will scarcely be contended that German, being highly inflected, is therefore superior in range and power to English, from which inflections have largely disappeared. Some of the early Jesuit missionaries, men of great natural ability who steeped themselves in Oriental learning, have left yet very different opinions on record. Chinese appeared to them as admirable for the superabundant richness of its vocabulary as for the conciseness of its literary style.

And among modern scholars there is a decided tendency to accept this view as embodying a great deal more truth than the other.

Another question, much debated years ago, which time itself has satisfactorily answered, was whether the Chinese language would be able to assimilate the vast stock of new terminology which closer contact with the West would necessarily carry with it. Two possible courses, it seemed, were open: either fresh characters would be formed on the radical-phonetic principle, or the new idea might be expressed by the conjunction of two or more characters already existing. The former expedient had been tried on a limited scale in Japan, where in the course of time new characters were formed on the same principle as of old, which were yet purely Japanese and find no place in a Chinese dictionary. But although the field for such additions was boundless, the Chinese have all along been chary of extending the language in this way, probably because these modern terms had no Chinese sound which might have suggested some particular phonetic. They have preferred to adopt the other method, of which 井 降機 (rise-descend-machine) for “lift,” and 義政國會 (discuss-govern-country-assembly) for “parliament” are examples. Even a metaphysical abstraction like The Absolute has been tentatively expressed by 繼 繼 ( exclude-opposite); but in this case an equivalent was already existing in the Chinese language.

A very drastic measure, strongly advocated in some quarters, is the entire abolition of all characters, to be replaced by their equivalent sounds in letters of the alphabet. Under this scheme a man would figure as jen or ren, 馬 as ma, and so on. But the proposal has fallen extremely flat. The vocables, as we have seen, are so few in number that only the colloquial, if even that, could possibly be transcribed in this manner. Any attempt to trans-literate classical Chinese would result in a mere jumble of sounds, utterly unintelligible, even with the addition of tone-marks. There is another aspect of the case. The characters are a potent bond of union between the different parts of the Empire with their various dialects. If they should ever fall into disuse, it now will have taken a first and most fatal step towards internal disruption. Even the Japanese, whose language is not only free from dialects, but polysyllabic and therefore more suitable for romanization, have utterly refused to abandon the Chinese script, which in spite of certain disadvantages has hitherto triumphantly adapted itself to the needs of civilized intercourse.

See P. Premare, Notitiae Linguarum Sinicarum (1831); Ma Kien-chung, Ma shih wén t’ung (1899); L. C. Hopkins, The Six Scripts (1881) and The Development of Chinese Writing (1910); H. A. Giles, A Chinese-English Dictionary (2nd ed., 1910). (H. A. Gl.: L. Gl.)

VIII. CHINESE LITERATURE

The literature of China is remarkable (1) for its antiquity, coupled with an unbroken continuity down to the present day; (2) for the variety of subjects presented, and for the exhaustive treatment which, not only each subject, but also each subdivision, each separate item, has received, as well as for the colossal scale on which so many literary monuments have been conceived and carried out; (3) for the accuracy of its historical statements, so far as it has been possible to test them; and further (4) for its embowering standards and lofty ideals, as well as for its wholesome purity and an almost total absence of corruption and obscenity.

No history of Chinese literature in the Chinese language has yet been produced; native scholars, however, have adopted, for bibliographical purposes, a rough division into four great classes. Under the first of these, we find the Confucian Canon, together with lexicographical, philological, and other works dealing with the elucidation of words. Under the second, histories of various kinds, officially compiled, privately written, constitutional, &c.; also biography, geography and bibliography. Under the third, philosophy, religion, e.g. Buddhism; the arts and sciences, e.g. war, law, agriculture, medicine, astronomy, painting, music and archery; also a host of general works, monographs, and treatises on a number of topics, as well as encyclopaedias. The fourth class is confined to poetry of all
descriptions, poetical critiques, and works dealing with the all-important rhymes.

Poetry — Proceeding chronologically, without reference to Chinese classification, we have to begin, as would naturally be expected, with the last of the above four classes. Man's first literary utterances in China, as elsewhere, took the form of verse; and the earliest Chinese records in our possession are the national lyrics, the songs and ballads, chiefly of the feudal age, which reaches back to over a thousand years before Christ. Some pieces are indeed attributed to the 18th century B.C.; the latest bring us down to the 6th century B.C. Such is the collection entitled Shih Ching (or She King), popularly known as the Odes, which was brought together and edited by Confucius, 551-479 B.C., and is now included among the Sacred Books, forming as it does an important portion of the Confucian Canon. These Odes, once over three thousand in number, were reduced by Confucius to three hundred and eleven; hence they are frequently spoken of as "the Three Hundred." They treat of war and love, of eating and drinking, of wealth, of virtue and vices of rulers, and of the misery and happiness of the people. The verse in rhyme. Rhyme is essential to Chinese poetry; there is no such thing as blank verse. Further, the rhymes of the Odes have always been, and are still, the only recognized rhymes which can be used by a Chinese poet, anything else being regarded as mere jingle. Poetical licence, however, is tolerated; and great masters have availed themselves freely of its aid. One curious result of this is that whereas in many instances two given words may have rhymed, as no doubt they did, in the speech of three thousand years ago, they no longer rhyme to the ear in the colloquial of to-day, although still accepted as true and proper rhymes in the composition of verse.

It is noticeable at once that the Odes are mostly written in lines of four words, examples of lines consisting of any length ranging single word to eight, though such do exist, being comparatively rare. These lines of four words, generally recognized as the oldest measure in Chinese poetry, are frequently grouped as quatrains, in which the first, second, third, and fourth lines rhyme; but very often only the second and fourth lines rhyme, and sometimes there are groups of a larger number of lines in which occasional lines are found without any rhyme at all. A few stray pieces, as old as many of those found among the Odes, have five or six lines each; and two of them, one by the master-hand of Mî Shêng, who died 140 B.C., consists of two lines of three words followed by one line of seven words. These three lines all rhyme, but the rhyme changes with each succeeding triplet. It would be difficult to persuade the English reader of the effect of Chinese dynastic poetry; indeed, in a gloomy or pathetic tale has been told. In order to realise how a few Chinese monosyllables in juxtaposition can stir the human heart to its lowest depths, it is necessary to devote some years to the study of verse.

At the close of the 4th century B.C., a dithyrambic measure, irregular and wild, was introduced and enjoyed considerable vogue. It has indeed been freely adopted by numerous poets from that early date to the present day; but since the 2nd century B.C. it has been displaced from pre-eminence by the seven-word and five-word measures which are now, after much refinement, the accepted standards for Chinese poetry. The origin of the seven-word metre is lost in remote antiquity; the five-word metre, however, is a result of the general development of the Chinese language, and was recognized in the earliest periods of the Han dynasty. The difference between the five-word and seven-word metres, as used down to the present time, is that the seven-word metre may only have a single rhyme, whereas the five-word metre may have two or even three rhymes. The five-word metre is found in all early Chinese poetry, from the 6th century B.C. on down to the present day; and the seven-word metre is found in nearly all the literatures of China.

A seven-word stanza may run:

<table>
<thead>
<tr>
<th></th>
<th>Flat</th>
<th>Sharp</th>
<th>Flat</th>
<th>Sharp</th>
</tr>
</thead>
<tbody>

The above are only two metres out of many, but enough perhaps to give to any one who will read them with a pause or quasi-caesura, an idea of the rhythm of Chinese poetry. To the trained ear, the effect is most pleasing; and when this scansion, so to speak, is united with rhyme and choice diction, the result is a vehicle for verse, artificial no doubt, and yet capable of output of verse of almost incredible extent. In 1707 an anthology of the T'ang poets was published by Imperial order; it ran to nine hundred books or sections, and contained over forty-eight thousand poems and separate lines. The poet of T'ang was almost as popular a sentiment as the poet of the Chinese department of the University Library at Cambridge. It was under the T'ang dynasty that a certain finality was reached in regard to the strict application of the tones to Chinese verse. For the purposes of poetry all words are divided into three distinct tones, or rhymes, under one of which rhyme follows another of two tones, the even and the oblique, the former now including the two even tones, of which prior to the 11th century there was only one, and the latter including the rising, sinking and entering tones. The tones of a word are not to be roughly described as sharps and flats, but finally became fixed, just as the incidence of certain feet in Latin metres came to be governed by fixed rules. Thus, reading downward from right to left, as Chinese, the five-word stanza may run:

<table>

The Mongols, A.D. 1260-1368, who succeeded the Sung, and the Ming who followed the Sung and bring us down to the year 1644, indeed, especially in the T'ang period, the Sung dynasty of the latter part of the 12th century, was a time of great literary activity, and the period immediately following saw the development of many new literary forms, including the essay and the diary. The A.D. 1300's was a period of great political and social change, and the literary scene was marked by the development of the novel, the drama, and the essay. The 17th century saw the rise of the novel, which became a popular form of literature, and the development of the drama, which became a popular form of entertainment. The 18th century saw the rise of the essay, which became a popular form of literary criticism, and the development of the novel, which became a popular form of fiction. The 19th century saw the rise of the novel, which became a popular form of literature, and the development of the drama, which became a popular form of entertainment. The 20th century saw the rise of the novel, which became a popular form of literature, and the development of the drama, which became a popular form of entertainment.
so in her poetic art is suggestiveness the great end and aim of the artist. Beginners are taught that the three canons of verse composition are lucidity, simplicity and correctness of diction. Yet some critics have boldly declared for obscurity of expression, alleging that the thought so expressed is enriched by its skillful concealment. For the foreign student, it is not necessary to accentuate the obscurity and difficulty even of poems in which the motive is simple enough. The constant introduction of classical allusions, often vague, involves an added sense and a greater limitation of the order of words, offer quite sufficient obstacles to easy and rapid comprehension. Poetry has been defined by one Chinese writer as “clothing with words the emotions which surge through the heart.”

The present school of Chinese poets is, in general, delighted with phenomena of nature, and a boundless sympathy with the woes and sufferings of humanity. Erotic poetry is not absent, but it is not a feature proportionate in extent to the great body of Chinese verse; it is always restrained, and never grossly or indecorously expressed. There is love for hills and stream which he peoples with genii, and for tree and flower which he endows with sentient souls, the Chinese poet is perhaps seen at his very best; his views of life are somewhat too deeply tinged with melancholy, and often loaded with an overwhelming sadness “at the double doom of human kind.” In his lighter moods he draws inspiration, and in his darker moods consolation from the wine-cup. Hard-drinking, not to say drunkenness, seems to have been universal among Chinese poets, and a considerable amount of talent has been expended upon the glorification of wine. From Taoist, and especially from Buddhist sources, many poets have obtained glimpses to make them less forlorn; but it cannot be said that there is any definitely religious poetry in the Chinese language.

History.—One of the labours undertaken by Confucius was connected with a series of ancient documents—that is, ancient in his day—now passing under a collective title as Shu Ching (or Shoo King), and popularly known as the Canon, or Book, of History. Mere fragments as some of these documents are, it is from their pages of unknown date that we can supplement the pictures drawn for us in the Odes, of the early civilization of China. The work opens with an account of the legendary emperor Yao, who reigned 2255–2253 B.C., and was able by virtue of an elevated personality to give peace and happiness to his “black-haired” subjects. In his reign he determined the summer and winter solstices, and calculated approximately the length of the year, availing himself, as required, of the aid of an intercalary month. Finally, after a glorious reign, he ceded the throne to a man of the people, whose only claim to distinction was his unwavering practice of filial piety. Chapter ii. deals with the reign, 2255–2252 B.C., of this said man, known in history as the emperor Shun. In accordance with the monothecism of the day, he worshipped God in heaven with prayer and bount offerings; he travelled on tours of inspection all over his then comparatively narrow empire; he established punishments, to be tempered with mercy; he appointed officials to superintend forestry, care of animals, religious observances, and music; and he organized a system of periodic examinations for public servants. Chapter iii. is devoted to details about the Great Yu, who reigned 2205–2197 B.C., having been called to the throne for his engineering success in draining the empire of a mighty inundation which early western writers identified with the Deluge. This long chapter gives various geographical details, and enumerates the articles, gold, silver, copper, iron, steel, silken fabrics, feathers, ivory, hides, &c., &c., brought under the reign of the Great Yu, as tribute from neighbouring countries. Other chapters include royal proclamations, speeches to troops, announcements of campaigns victoriously concluded, and similar subjects. One particularly interesting document is the Announcement against Drunkenness, which seems to have been for so many centuries a national vice, and then to have practically disappeared as such. For the past two or three hundred years, drunkenness has always been the exception rather than the rule. The Announcement, delivered in the 12th century b.c., points out that King Wen, the founder of the Chou dynasty, had wished for wine to be used only in connexion with sacrifices, and that divinities had always been literally showered upon the people when such a restriction had been observed. On the other hand, indulgence in strong drink had invariably attracted divine vengeance, and the fall and disruption of states had often been traceable to that cause. Even on sacrificial occasions, drunkenness is to be condemned. “When, however, you high officials and others have done your duty in ministering to the aged and to your sovereign, you may then eat to satiety and drink to elevation.” The Announcement winds up with an ancient maxim, “Do not seek to see yourself reflected in water, but in others”—whose base actions should warn you not to commit the same; adding that those who after a due interval should be unable to give up intemperate habits would be put to death. It is worth noting, in concluding this brief notice of China’s earliest records, that from first to last there is no mention whatever of any distant country from which the “black-haired people” may have originally come; no vestige of any allusion to any other form of civilization, such as that of Babylonia, with its cuneiform script and baked-clay tablets, from which an attempt has been made to derive the native-born civilization of China. A few odd coincidences sum up the chief argument in favour of this now discredited theory.

The next step leads us on the confines, though scarcely in the domain, of history properly so called. Among his other literary labours, Confucius undertook to produce the annals of Lu, his native state; and beginning with the year 722 B.C., he carried the narrative forward to the death of his pupil Ch’iu in 479, after which it was continued for a few years, presumably by Tso-ch’iit Ming, the shadowy author of the famous Commentary, to which the text is so deeply indebted for vitality and illumination. This work on the annals of Lu, as Confucius himself wrote it, was divided into nine books, with a central sacerdotal, and all subsequent history is an augmentation of it. For the first time, a record of the official annals has been employed in the construction of history, an achievement which was especially requisite for a people to which the very concept of a central sacerdotal, had already broken hopelessly down, so far as allegiance was concerned. For some time, the object of the local annals had been the advancement of his own state, with a view to inducing the people to indulge in such pious observances as religious ceremonies, &c., interspersed with notices of striking natural phenomena as eclipses, comets and earthquakes, and of important national calamities, such as floods, drought and famine. For instance, Duke Wu became ruler of Lu in 652 B.C., and under his 14th year, 612 B.C., we find twelve entries, of which the following are specimens:—

1. In spring, in the first month, the men of the Chü State invaded Shoo for sugar-cane.

2. In spring, on the 1st day of the fifth month, P’an, Marquis of the Ch’i State, died.

3. In autumn, in the seventh month, there was a comet, which entered Pei-tou (a star in Ursa Major).

4. In the ninth month, a son of the Duke of Ch’i murdered his ruler.

Entry 5 affords the earliest trustworthy instance of a comet in China. A still earlier comet is recorded in what is known as The Bamboo Annals, but the genuineness of that work is disputed.

It will be readily admitted that the Ch’u Ch’iit, written throughout in the same style as the quotations given, would scarcely enable one to reconstruct in any detail the age it professes to record. Happily, we are in possession of the Tso Ch’un, a so-called commentary, presumably by some one named Tso, in which the bald entries in the work of Confucius are separately enlarged upon to such an extent and with such dramatic brilliancy that our commentary, or marginal notes, through the medium of which we trace a systematic series of comments or annotations on the text of a literary work.” Under its guidance we can follow the intrigues, the alliances, the treacheries, the ruptures of the jealous states which constituted fourteen in number, in the year 584, in which year the war must have ended, and the total destruction of a state by its own eyes, assassinations, battles, heroic deeds, flights, pursuits and the sufferings of the vanquished from the retribution exacted by the victors. Numerous wise and witty sayings are scattered throughout, and many famous deeds are presented to the history.

History as understood in Europe and the west began in China with the appearance of a remarkable man, Ts’ai-ma Ch’ien, who flourished 445–87 B.C., was son of a hereditary grand astrologer, and was long before the days of the Ch’ou dynasty to whom the great work so successfully carried out after his death. By the time he was ten years of age, Ts’ai-ma Ch’ien was already well advanced with his studies; and at twenty he set forth on a round of travel which carried him to all parts of the empire. Entering the public service, he was employed upon a mission of inspection to the newly-conquered regions of Shu’suan and Yün-nan; in 110 B.C. his father died, and he stepped into the post of grand astrologer. After devoting some time and energy to the reformation.
of the calendar, he took up the work which had been begun by his father and which was ultimately given to the world as the Shih Chi, or Historical Record. This was arranged under five great headings, namely, (1) Annals of Imperial Reigns, (2) Chronological Tables, (3) Mummified Texts, and (4) Vassal States.

The Historical Record begins with the so-called Yellow Emperor, who is said to have come to the throne 2968 B.C. and to have reigned a hundred years. Four other emperors are given, as belonging to the period after the Yellow Emperor, by early Chinese narratives. The Chou dynasty, 1122–255 B.C., had held sway for some three hundred years can we be said to have reached a point at which history begins to separate itself definitely from legend. In fact, it is only from the 1st century B.C. that we have a definite account of the lives of individuals, which is traditionally said to have been written by Ssu-ma Ch'ien, who lived at the close of the Ch'in dynasty.

In 221 B.C. he proclaimed himself the "First Emperor," a title which he has ever since been known. Everything, including literature, was to begin with his reign; and acting on the advice of his prime minister, he ordered the destruction of all books, with the exception only of works relating to medicine, divination and agriculture. Those who wished to study law were referred for oral teaching to such as had already qualified in that profession. To carry out the scheme, he had books written upon them every day about 120 lb. weight of books, in order to get rid of such as he considered to be useless; and he further appointed a number of inspectors to see that his orders were carried out. The result was that, according to tradition, much of the literature of China was destroyed, and that the emperor, having disobeyed the imperial command, while many others were banished for life. This incident is known as the Burning of the Books; and there is little doubt that, but for the devotion of the library lovers of Chinese literature would have had to make a fresh start.

As it was, books were bricked up in walls and otherwise widely concealed in the hope that the storm would blow over; and this was actually the case when the Chi (Ts'in) dynasty collapsed and the Ch'in (H'shoo) dynasty of the Han was placed on the throne. The new dynasty, however, were subsequently recovered from their hiding-places, together with many other works, the loss of which is difficult now to contemplate. Unfortunately, however, a stimulus was provided, not for the recovery, but for the writing of new and better works. This was the result in which could be gathered either from tradition or from notices in the various works which had survived. Fargory became the order of the day; and the modern student is confronted with a considerable volume of literature, which has to be classified as genuine, doubtful or spurious, according to the merits of each case. To the first class belongs the bulk, but not all, of the Confucian Canon; to the second must be relegated such books as the Ts'ao T's'e Ch'in, to be mentioned later on.

After the first three chapters, the art of writing in Chinese literature began to be developed and the opening reigns of the Han dynasty, with which he brings into a close the first great division of his history. The second division consists of chronological tables; the third, of eight monographs on the following topics: (1) The History of the Han dynasty, (2) The History of the Han territory, (3) The Chang, (4) The Calendar, (5) Astronomy, (6) Religion, (7) Water-ways, and (8) Commerce. On these eight a few remarks may not be out of place.

The Chinese seem to have been in possession, from very early ages, of a systematic code of farming manuals, and to have devoted much attention to the study of astronomy. There is no surprise to find the subject included, and taking an important place, in Ssu-ma Ch'ien's work. The Li Chi, or Book of Rites, which now forms part of the Confucian Canon, is however a comparatively modern book, dating only from the 1st century B.C. (2) History and the extraordinary similarities between the Chinese and Pythagorean systems of music force the conclusion that one of these must necessarily have been derived from the other. The Jesuit Fathers jumped to the conclusion that the Chinese had got their system from the Greeks; but it is now common knowledge that the Chinese scale did not exist in China until two centuries after its appearance in Greece. The fact is that the ancient Chinese works on music perished at the Burning of the Books, and all that we have known of the music of the Chinese is from the 1st century B.C. (3) The term Natural Philosophy can only be applied by courtesy to this essay, which deals with twelve bamboo tubes of varying lengths, by means of which, coupled with the twenty-eight-zodiacal signs, their appropriate pitches are established. Music and meteorology was established with the influences of the five elements and the points of the compass corresponding with the eight winds.

In this connexion, it is worth noting that in 104 B.C. the Chinese first laid the foundation of a cycle of nineteen years, a period which exactly brings together the solar and the lunar years; and further that this very cycle is said to have been introduced by Methon, 5th century B.C., and adopted at Athens about 330 B.C., probably reaching China, via Bactria, some two centuries afterwards. (5) This chapter deals specially with the sun, moon and five planets, which are supposed to aid in the divine government of mankind. (6) Refers to the solemn sacrifices to Heaven and Earth, as performed by the emperor upon the summit of Mt. Tai Shan-tung. (7) Refers to the management of the empire, to his concern for his people, and to his reverence for his ancestors; of which is his practice of "China's Sorrow," and also of the numerous canals with which the empire is intersected. (8) This chapter, which treats of the circulation of money, and its function in the Chinese theory of political economy, it is perhaps worth mentioning that the Chinese, with their system of "credit" business it was to regularize commerce. It was their duty to buy up the chief necessaries of life at abundant and when prices were in consequence low, and to offer these for sale when there was a shortage and prices were high. This practice was later taken up by the Romans, and was followed by the English, who substituted remittances to the foreigner by letters of credit. (9) This chapter is a commentary on Confucius and his disciples with particular reference to the "Spring and Autumn," the exquisite little set of historical commentaries, which have survived.

Ssu-ma Ch'ien's great work, on which he laboured for so many years and which ran to five hundred and twenty-six thousand five hundred words, has been described somewhat at length for the following reasons: (1) It contains invaluable documents and fascinating stories of the Chinese dynasties. (2) It is a gem of its kind, and has been called the "mirror of history." The whole of the first five centuries is the history of the Ch'in dynasty, which first arose in the 6th century B.C., and which supplanted that of the Chou. Meton, A.D. 581–906, offers in one sense a curious exception to the general rule. It possesses two histories, both included in the above series. The first of these, now known as the Old Ts'ang History, was eventually set upon and destroyed by each succeeding dynasty. The second, which has come down to us, was compiled by Ou-yang Hsü, a distinguished scholar, poet and statesman of the 11th century. Nevertheless, in all cases, the scheme of the dynastic history has, with certain modifications, been that which was initiated in the 1st century B.C. by Ssu-ma Ch'ien, and which was continued by the famous commentator, who flourished A.D. 1130–1200, and whose work is now regarded as the standard history of China.

Biography.—In regard to biography, the student is by no means limited to the dynastic histories. Many large bibliographical collections have been compiled and published by private individuals, and many lives of the same personages have been written from different points of view. There is nothing very much by which a Chinese biography can be distinguished from biographies produced in other parts of the world. The Chinese writer always begins with the place of birth, but he is not so particular about the year, sometimes leaving that to be gathered from the date of death taken in connection with the age which the person may have attained. Some allusion is usually made to ancestry, and the steps of an official career, upward by promotion or downward by disgrace, are also carefully noted.

Geography and Travel.—There is a considerable volume of
Chinese literature which comes under this head; but if we exclude certain brief notices of foreign countries, there remains nothing in the way of general geography which had been produced prior to the 1st century B.C. The earliest work at the close of the 6th century. Up to that period geography meant the topography of the Chinese empire; and of topographical records there is a very large and valuable collection. Every prefecture and department, some a hundred in all, has each its own particular topography, compiled from records and from tradition with a fullness that leaves nothing to be desired. The buildings, bridges, monuments of archaeological interest, &c., in each district, are all carefully inserted, side by side with biographical and other local details, always of interest to residents and often to the outside public. An extensive geographical survey of the empire was last published in 1745; and this was followed by a chronological geography in 1794.

The Chinese have always been fond of travel, and hosts of travellers have published notices, more or less extensive, of the different parts of the empire, and even of adjacent nations, which they visited either as private individuals or, in the former case, as officials proceeding to distant posts. With Buddhism came the desire to see the country which was the home of the Buddha; and several important pilgrimages were undertaken with a view to bring back images and sacred writings to China. On such a journey the Buddhist priest, Fa Hsien, started in A.D. 399; and after practically walking the whole way from central China across the Tarim desert, Khotan, and across the Hindu Kush into India, he visited many of the chief cities of India, until at length reaching Calcutta he took ship, and after a most adventurous voyage, in the course of which he remained two years in Ceylon, he finally arrived safely, in A.D. 414, with all his books, pictures, and images, at a spot on the coast of Shantung, near the modern German port of Kiaochow.

Another of these adventurous priests was Hsuan Tsang (wrongly, Yiian Chwang), who left China on a similar mission in 629, and returned in 645, bringing with him six hundred and fifty-seven Buddhist books, besides many images and pictures, and one hundred and fifty relics. He spent the rest of his life in translating, with the help of other learned priests, these books into Chinese, and completed in 648 the important record of his own travels, known as the Record of Western Countries.

**Philosophy.**—Even the briefest résumé of Chinese philosophical literature must necessarily include the name of Lao Tsâ, although his era, as seen above, and his personality are both matters of the vaguest conjecture. A number of his sayings, scattered over the works of early writers, have been pieced together, with the addition of much incomprehensible jargon, and the whole has been given to the world as the work of Lao Tsâ himself, said to be of the 6th century B.C., under the title of the Tao Tê Ching. The internal evidence against this book is overwhelming; e.g., one quotation has been detached from the writer who preserved it, with part of that writer's text clamping it to—of course by an oversight. Further, such a treatise is never mentioned in Chinese literature until some time after the Burning of the Books, that is, about four centuries after its alleged first appearance. Still, after due expurgation, it forms an almost complete collection of such apothegms of Lao Tsâ as have come down to us, from which the reader can learn that the author taught the great doctrine of Inaction—Do nothing, and all things will be done. Also, that Lao Tsâ anticipated the Christian doctrine of returning good for evil, a sentiment which was highly reprobated by the practical mind of Confucius, who declared that evil should be met by justice.

Among the more picturesque of his utterances are such paradoxes as, "He who knows how to shut, uses no bolts; yet you cannot open. He who knows how to bind uses no ropes; yet you cannot untie." "The weak overcomes the strong; the soft overcomes the hard," &c.

These, and many other subtleties of speech, seem to have fired the imagination of Chuang Tsâ, 4th and 3rd centuries B.C., with the result that he put much time and energy into the glorification of Lao Tsâ and his doctrines. Possessed of a brilliant style and a master of irony, Chuang Tsâ attacked the schools of Confucius and Mo Ti (see below) with so much dialectic skill that the ablest scholars of the age were unable to refute his system. Both criticise and ridicule the mystic, and deal with all the mystic's contempt for a life of mere external activity. Only thirty-three chapters of his work now remain, though so many as fifty-three are known to have been still extant in the 3rd century; and even of these, several complete chapters are spurious, while in other cases the whole tenor of character has been changed by the interpolator. What remains, however, after all reductions, has been enough to secure a lasting place for Chuang Tsâ as the most original of China's philosophical writers. His book is of course under the heading of inspiration, and, like the other Confucian teachings, it views as mystic, idealist, moralist, and social reformer have no weight with the aspirant who has his way to make in official life; but they are a delight, and even a consolation, to many of the older men, who have no longer anything to gain or to lose.

Confucius. His talks with his disciples and with others have been preserved for us, in what is known as the personal and private life; and the volume in which these are collected forms one of the Four Books of the Confucian Canon. Starting from the axiomatic declaration that man is born good and only becomes evil by evil influence from his environment, he takes the reader on a journey from childhood to old age, illustrated by a host of anecdotes, with an occasional hint of a mystic, with almost Johnsonian emphasis. He cherished a shadowy belief in a God, but not in a future state of reward or punishment for good or evil actions in this world. He rather taught men to be virtuous for virtue's sake.

Mencius. Mencius devoted his life to elucidating and expanding the teachings of the Master; and it is no doubt due to him that the Confucian doctrines obtained so wide a vogue. But he himself was a politician and an economist (see below) than a simple preacher of morality; and hence it is that the Chinese philosopher is accorded to him the title of the Second Sage. He is supposed to have effectually "snuffed out" the heterodox school of Mo Ti, a philosopher of the 5th and 4th centuries B.C., who propounded a doctrine of "universal love" as the proper foundation for organized society. He taught that, in a word, "a man who in his dealing with men like himself will not try to bring one another to be like themselves, and the Golden Age be renewed. At the same time Mencius exposed the fallacies of the speculations of Yang Chu, 4th century B.C., who, though he disavowed the dogma, and in conformity with Christian doctrine, that the nature of man at his birth is evil, and that this condition can only be changed by efficient moral training, then came Yang Hsiung, 53-18 B.C., who founded an ethical criterion midway between the two, and, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.

Mo Ti. Another early philosopher is Hsün Tsâ, 3rd century B.C. He maintained the opposition to Mencius, who upheld the Confucian dogma, and, in conformity with Christian doctrine, that the nature of man at his birth is evil, and that this condition can only be changed by efficient moral training. Then came Yang Hsiung, 53-18 B.C., who, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.

Yang Chu. And other early philosophers, Liu Hsiung, 4th century B.C., who, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.

Hsün Tsâ. Hsün Tsâ, 3rd century B.C., who, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.

Yang Hsiung. Yang Hsiung, 53-18 B.C., who, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.

Hsiün Tsâ. Hsiün Tsâ, 3rd century B.C., who, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.

Chuang Tzâ. Chuang Tzâ, 4th century B.C., who, by definition and argument, arrived at a system of ritualism, that man is by nature good, but that a mixture of both, and that development in either direction depends wholly upon circumstantial circumstances.
in considerable numbers; but almost all of them have given their attention to textual criticism of the Confucian Canon, and few have condescended to examine critically the works of heterodox writers. The foreign student therefore finds himself faced with many knotty problems to solve.

Of Wang Ch'ung, a speculative and materialistic philosopher, A.D. 27-97, banned by the orthodox for his attacks on Confucius and Mencius, only one work has survived. It consists of eighty-four chapters, the subject of which is the things of the world, its origin, its meaning, and the end. It contains the views in the Book of Changes, and the views of Confucius and Mencius on the same subjects. The work is written in a spirit of ironical ridicule.

Wang Ch'ung. The work postulated that the human body is governed by the laws of nature, and that a certain class of scholars was "dis pleased" in consequence, whereupon the Master swore, saying, "I will not destroy the human body!" He then made the following statement: "I will not destroy the human body!"

But did the sky fall? No, Wang Ch'ung points out that the form of our body is changed for the sake of the vital fluid leads to insanity. Without the fluid, the body cannot be maintained; without the body, the soul loses its vitality. Therefore, argues Wang Ch'ung, when the body perishes and the fluid is lost, what remains of man is a mere shadow. For this reason, there is nothing immortal in a life beyond the grave. Graves he held to be the hallucinations of disordered minds, and miracles to be natural phenomena capable of simple explanations. His indecisions and his acceptance of the doctrines of the Mahayana school are, however, contrary to what he believed in the main body of his work.

This work was written in opposition to the popular belief in the immortality of the soul, and to the idea that the soul was able to live after death without the body. The work was, however, a great success, and it was rapidly adopted by all classes, and became a standard work in China. The work was written at a time when the Chinese people were suffering from the effects of the Great Leap Forward, and the work was intended to provide a means of escape from the material world, and to provide a means of salvation for those who were unable to escape.

Mencius (see above) was in favour of heavily taxing merchants who tried to engross for the purpose of reaping, that is, to buy up wholesale for the purpose of reselling at a monopoly prices. He was in fact opposed to all trusts and corners in trade. He was in favour of a tax on land and a tax on goods, and he also opposed the practice of the opium trade, which was controlled by the government. He also opposed the practice of the opium trade, which was controlled by the government. He also opposed the practice of the opium trade, which was controlled by the government.

Wang An-shih, the Reformer, or Innovator, as he has been called, followed the line of thought opened up by the former. He proposed a series of reforms, and then went on to work out a series of startling reforms, which have given him a unique position in the annals of China. He established a state monopoly in commerce, and he also introduced a system of taxation on the land, which was based on the amount of land owned by the individual. He also introduced a system of taxation on the land, which was based on the amount of land owned by the individual.

Military Writers.—Not much, relatively speaking, has been written by the Chinese on military strategy. There is, however, a great deal of literature on military matters, and one of the books of this kind is Sun Tzu's "The Art of War," which was written in the 6th century B.C. This work is a treatise on military strategy, and it contains many valuable ideas on the conduct of war, and on the psychology of warfare.

Sun Tz'u. A.D. 544-496, was an officer of the state of Ch'in. He wrote "The Art of War," which is a treatise on military strategy, and it contains many valuable ideas on the conduct of war, and on the psychology of warfare.

The work is divided into sixteen chapters, and each chapter contains a number of rules, or "maxims," which are intended to guide the general in the conduct of war. The rules are divided into two main classes, namely, those relating to the conduct of war in general, and those relating to the conduct of war in particular situations. Medicine and Therapeutics.—The oldest of the innumerable medical works of all descriptions with which China has been flooded from time immemorial is a treatise which has been credited to the Yellow Emperor (see above), 2698–2598 B.C. It is entitled Pien Ts‘ao, or "Pharmaceutical Treatise." It is said to have been written long before the common era; it is now in 12 sections, each of which is marked by a question put by the emperor and answered by Earl Ch‘i, a minister, who was himself author of the Nei Ching, a medical work no longer in existence. Without accepting the popular attribution of the Si Wu Ch‘i, the book is very valuable as a historical record of work that was being done several centuries before Christ, and containing traditional lore of a still remote period. The same may be said of certain works on cautery and acupuncture, both of which are still practised by Chinese medical men. There are also a number of other works which have been classified and allocated with a minuteness hardly credible. Special treatises on fevers, skin-diseases, diseases of the feet, eyes, heart, &c., are to be found in great quantities, as well as veterinary treatises on the treatment of diseases of the horse and of other animals. But in the whole range of Chinese medical literature there is nothing which can approach the Pien Ts‘ao, or "Pharmaceutical Treatise," as an authoritative and valuable work, yet compiled by Li Shih-ch‘en, who completed his task in A.D. 1578 after twenty-six years' labour. No fewer than eighteen hundred and ninety-two species of drugs, animal, vegetable and mineral, are dealt with in this treatise. Of the drugs, no less than one-third are herbs, thousand one hundred and sixty prescriptions are given in connexion with the various entries. The author professed to quote from the original Pien Ts‘ao, above mentioned; and we obtain from his work a valuable vegetable and mineral materia medica. Each of the number of recognized drugs was three hundred and sixty-five in all, corresponding with the days of the year. One hundred and twenty-two of these were called Sovereign, (a sovereign prescription); and, therefore, should be used only by a skilful doctor, with discretion, and within the limits of his own practice, quantity or for any time. Another similar number were called ministers; some of these were poisonous, and all had to be used with discretion. The remaining one hundred and fifty-two were again divided into four classes, and yet another division being given according to the rate at which each drug will do harm or damage. The Modern Pien Ts‘ao, in its sixteen divisions, deals with drugs classed under water, fire, earth, minerals, herbs, grain, vegetables, fruit, trees, clothes and utensils, insects, fishes, crustaceans, birds, and animals. A number of each class is given, followed by its explanation, solution of doubtful points, correction of errors, and definition of taste, use in prescriptions, &c. The work is fully illustrated, and there is an index to the various medicines, classified according to the complaints for which they are used. 

Divination, &c.—The practice of divination is of very ancient date in China, traceable, it has been suggested, back to the Canon of Changes (see above), which is commonly used by the lettered classes for that purpose. A variety of other methods, the chief of which is astrology, have also been adopted, and have yielded a considerable bulk of literature. Even the officially-published almanacs still mark certain days as suitable for various purposes, while the indications of the stars are made use of in the same sense. The spirit of Zhadzki pervades the Chinese empire. In like manner, geomancy is a subject on which many volumes have been written; and the same applies to the pseudo sciences of palmistry, physiognomy, alchemy (introduced from the west), &c. 

Painting.—Calligraphy, in the eyes of the Chinese, is just as much a fine art as painting; the two are, in fact, considered to have come into existence together, but as might be expected the latter occupies the larger space in Chinese Art. They are but forms of the subject in numerous extensive works. One of the most important of these is the Hsian Hsii Hua, the author of which is unknown. It contains information concerning two hundred and thirty-one painters and the titles of the pictures they have done. This work has been translated into several of the modern languages, and is well known in the imperial collection during the dynastic period Hsien Ho, A.D. 1119–1126, from which the title is derived. The artists are classified under one of the following ten headings, supposed to represent the different schools and styles. The work was published each year by the Emperor of the Northern Sung, Human Figures, Buildings, Barbarians (including their Animals), Dragons and Fishes, Landscape, Animals, Flowers and Birds, The Bamboo, Vegetables and Fruits. 

The Chinese impression does not go back to a remote period. The Canon of Music, which was formerly included in the Confucian Canon, has been lost for many centuries; and the works now available, exclusive of entries in the dynastic histories, are not older than the twelfth century. The Ch‘i lung Lu, a treatise on the deaf and blind which dates from 9th century, is also of much importance, and it is said that the instruments are given, with measurements in each case, and the special notations required. 

Miscellaneous.—Under this head may be grouped a vast number of works, some of which are of value, on such topics as archaeology, seals (engraved), numismatics, pottery, ink (the so called "Indian ink"), mirrors, precious stones, tea, wine, chess, wit and humour, even cookery, &c. There is, indeed, hardly any subject, within reasonable limits, which does not find some connection in Chinese literature. 

Collections.—Reprints of miscellaneous books and pamphlets in a uniform edition, the whole forming a "library," has long been a favorite Institution on the part of Chinese scholars and students. One of the most extensive is the "A Collection of the best works of the various schools," containing over ten thousand volumes, and consisting of a great variety of books, with explanations; a short account of fabulous regions to the No. 8. 2. and W.; notes on the plants and trees of southern countries; bibliographical sketches of ninety-two wonderful personages; an account of the various schools of astronomy, the rise and progress of the arts of healing, the height, length of limb, &c., of the ideal woman; "Pien Ts‘ao," (a term borrowed by the Japanese), or jottings on various subjects, ranging from the Creation to an account of Fungus, a country where the trees are thousands of feet high and of vast girth, thus supporting the theory of the existence of an old line of development, the first men being there for the purpose of making a study of the vegetation; critiques on the style of various poets, and on the indecency of each to earlier writers; a list of the most famous bronze vessels cast by early emperors, with their dimensions, inscriptions, &c.; a treatise on the zones of the land, the walls of the earth, the fire, &c.; an account of the old Mongol palace, previous to its destruction by the first Ming emperor; notes on the wild tribes of China; historical episodes; biographical notices of one hundred and four sovereigns, and two hundred ancient sub-lieutenants; the names of the various animal and natural and other topics, first published in the 15th century; notes for bibliophiles on the care of books, and on paper, ink, pictures, and bric-a-brac; a collection of famous criminal cases; night thoughts suggesting the use of certain drugs; the laws and maxims of the ancient emperors, relating to magic, dreams, biloconation, and to almost every possible shade of supernatural manifestation, and the reader will have some idea of what he may expect in an ordinary "library" of a popular nature. The Chinese, as a nation, must be included among the artistic nations, and, for example, in the style of the book, is of paramount importance. Documents, the subject-matter of which would be recognized to be of no educative value, would still be included, if written in a pleasing style, such as might be serviceable as a guide to various pastimes. 

Individual Authors.—In a similar manner it has always been customary for relatives or friends, sometimes for the trade, to publish the complete works of important and often unimportant writers; usually a fat line of dust at the beginning of each work, as follows is, almost invariably led to high office under the state, the collected works of the great majority of authors open with selected Memoirs to the Throne and other documents of an official character. The public interest in these may have long since passed away but they are valued by the Chinese as models of a style to be imitated, and the foreign student occasionally comes across papers on once burning questions arising out of commercial or diplomatic intercourse with western nations. Then may follow—the order is not always the same—the preface, which the author contributes, historical, or superincumbent to the literary undertakings of his friends. Preface-writing is almost a department of Chinese literature. No one ever thinks of publishing a work without getting one or more of his capable associates to provide prefaces. The Chinese are well acquainted with the fact that they are always couched in highly-polished and obscure terms, the difficulty of the text being often aggravated by a fanciful and almost illegible script. Prefaces written by emperors, many examples of which may be found, are covered with coats of arms, official gifts, and lines of coloured ink. The next section may comprise bibliographical notices of eminent men and women, or of mere local celebrities, who happened to die in the author's day. Then will follow Records, a title which is commonly used to cover inscriptions cut on the walls of the building, or in the case of inscriptions; and also notes on pictures which the author may have seen, places which he may have visited, or allegorical incidents which he may have imagined. Then come disquisitions, or essays on various subjects, and the whole forms a very entertaining part of the book, and will be the most Logical interest; studies or monographs; birthday congratulations to friends or to official colleagues; announcements, as to deities, a cessation of whose worship is threatened if the necessary rain or fair winds do not come. Then will follow catalogues of objects of interest, such as the works of art, which are given in the national libraries. The above items will perhaps fill half a dozen volumes; the remaining volumes, running to twenty or thirty in all, as the case may be, will contain the author's poetry, together with his longer works, which necessarily form the most essential part of such a collection is, in Chinese eyes, its completeness. 

Fiction.—Although novels are not regarded as an integral part of literature proper, it is generally conceded that some novels may be profitably studied, if for no other reason, from the point of view of style. With the novel, however, we are no longer on perfectly safe ground in regard to that decadence which characterizes, as has been above stated, the vast mass of Chinese literature. Chinese novels range, in this sense, from the simplest and most unaffected tale of daily life, down to low—nott the lowest—depths of objectionable pornography. The San Kuo Chih, an historical romance based upon a period of disruption at the close of...
and 2nd century A.D. is a delightful book, packed with episodes of battle, heroism, self-sacrifice, skilful strategy, and all that goes to make up a stirring picture of stirring times. Its author, who might almost have been Walter Scott, cannot be named for certain; but the work itself probably belongs to the 13th century, a date at which the novel begins to make its appearance in China. Previous to that time, there had been current an immense quantity of stories of various kinds, but nothing like a novel, as we understand the term. From the 13th century onwards, the growth of the novel was continuous; and finally, in the 17th century, a point was reached which is not likely to be surpassed. The *Hong Lou Meng*, the author of which took pains, for political reasons, to conceal his identity, is a creation of a very high order. Its plot is intricate and original, and the dénouement startlingly tragic.

In the course of the story, the chief clue of which is love, woven in with intrigue, ambition, wealth, poverty, and other threads of human life, there occur no fewer than over four hundred characters, each one possessed of a distinctive personality drawn with marvellous skill. It contains incidents which recall the licence tolerated in Fielding; but the coarseness, like that in Fielding, is always on the surface, and devoid of the ulterior suggestiveness of the modern psychological novel. But perhaps no work of fiction has ever enjoyed such vogue among literary men as a collection of stories, some graceful, some coarse, written in 1679 by Pu Sungling, a disappointed candidate at the public examinations. This collection, known as the *Liao Chai*, is exceedingly interesting to the foreign student for its sidelights on folklore and family life; to the native scholar, who professes to smile at the subject-matter as beyond the pale of genuine literature, it is simply invaluable as an expression of the most masterly style of which his language is capable.

**Drama.**—Simultaneously with the appearance of the novel, stage-plays seem to have come into existence in China. In the earliest ages there were set dances by trained performers, to the accompaniment of music and singing; and something of the kind, more or less ornate as regards the setting, has always been associated with solemn and festive occasions. But not until the days of the Mongol rule, A.D. 1260-1368, can the drama properly be said to have taken root and flourished in Chinese soil. The probability is that both the drama and the novel were introduced from Central Asia in the wake of the Mongol conquerors; the former is now specially essential to the everyday happiness of the Chinese people, who are perhaps the most confirmed playgoers in the world. There is an excellent collection of one hundred plays of the Mongol dynasty, with an illustration to each, first published in 1615; there is also a further large collection, issued in 1845, which contains a great number of plays arranged under sixty headings, according to the style and purport of each, besides many others. There is one famous play of the Mongol period which deals largely in plot and passion, and is a great favourite with the educated classes. It is entitled *Hsi Hsiang Chi*, or the Story of the Western Pavilion; and as if there were a double as to the reception which would be accorded to the work, a minatory sentence was inserted in the prolegomena: "If any one ventures to call this book indecent, he will certainly have his tongue torn out in hell." So far as the written play is concerned, its language is altogether unobjectionable; on the stage, by means of gags and gesture, its presentation is often unseemly and coarse. What the Chinese playgoer delights in, as an evening's amusement, is a succession of plays which are more of the nature of sketches, slight in construction and generally weak in plot, some of them based upon striking historical episodes, and others dealing with a single humorous incident.

**Dictionaries.**—The *Erh Ye*, or Nearing the Standard, is commonly classed as a dictionary, and is referred by native scholars generally to the 12th century A.D. The entries are arranged under nineteen heads, to facilitate reference, and explain a large number of words and phrases, including names of beasts, birds, plants and fishes. The work is well illustrated in the large modern edition; but the actual date of composition is an entirely open question, and the insertion of woodcuts must necessarily belong to a comparatively late age (see *Military Writers*).

With the *Shuo Wen*, or Explanation of Written Words, we begin the long list of lexicographical works which constitute such a notable feature in Chinese literature. A scholar, named Hsi Shên, who died about A.D. 120, made an effort to gather together all the characters in his own day; he then proceeded to arrange these characters—about ten thousand in all—on a system which would make it possible to give words without having to search through the whole book. To do this, he simply grouped together all such as had a common part, more or less indicative of the meaning of each, much as though an English dictionary were to consist of such groups as *Dog-days*, *Dog-kennel*, *Dog-collars*, *Dog-meat*, *Dog-nap*, and so on.

Hsi Shên selected five hundred and forty of these common parts, or Radicals (see *Language*), a number which, as will be seen later on, was found to be cumulously large; and under each Radical he inserted all the characters belonging to it, but with no particular order or arrangement, so much research being involved in many cases, quite a laborious task. The explanations given were chiefly intended to establish the pictorial origin of the language; but whereas no one now disputes this as a general conclusion, the steps by which Hsi Shên attributed to the Radical system given words without having to search for them have been adopted by reference, for instance, to the broken-down (see Hsi-shan Tsa).

Passing over a long series of dictionaries and vocabularies which appeared at various dates, some constructed on Hsi Shên's plan, with modifications and improvements, and others, known as phonetic dictionaries, arranged under the finals according to the Tones, we come to the great standard lexicon produced under the auspices, and now bearing the name of the emperor K'ang Hsi, A.D. 1662-1723.

But before proceeding, a rough attempt may be made to exhibit in English terms the principle of the phonetic as compared with the radical dictionary described above. In the spoken language there would occur the word *light*, the opposite of dark, and this word would be expressed in writing by a certain symbol. Then, when it became necessary to write down *light*, the opposite of heavy, the result would be precisely what we see in English. But as written words increased, always with a limited number of vocabularies (see *Language*), this system was found to be impracticable, so that the phonetic was laid down, consisting of a distinguishing kind of *light* from another, but without altering the original sound. Now, in the phonetic dictionary the words are no longer arranged in such groups as *Sun-light*, *Sun-burn*, *Sun-stroke*, *Sun-god*, and so on, according to the Radicals, but in such groups as *Sun-light*, *Moon-light*, *Foot-light*, *Gas-light*, and so on, according to the phonetics, all the above four being pronounced simply *light*, without reference to the radical portion which guides towards the limited sense of the term. So, in a phonetic dictionary, we should have such a group as *Brass-bound*, *Morocco-bound*, *Half-bound*, *Spell-bound*, *Homeward-bound*, *Wind-bound*, and so on, all the above six being pronounced simply *bound*. To return to *K'ang Hsi*, as the lexicon in question is familiarly styled, the total number of characters given therein amounts to over forty-four thousand, grouped no longer under the five hundred and forty Radicals of Hsi Shên, but under the much more manageable number of two hundred and fourteen,
as already used in earlier dictionaries. Further, as the groups of characters would now be more than four times as large as in the Shuo Wen, they were subdivided under each Radical according to the number of strokes in the other, or phonetic part of the character. The radicals (character-heads), which are not the same as the strokes, but are formed from them, should have "dog-nap" in the group of Radical "dog" and three strokes, while "dog-days" and "dog-meat" would both be found under Radical "dog" with four strokes, and so on. The two hundreds Radicals in the Shuo Wen were increased to one thousand, according to the number of strokes; so that it is not a very arduous task to turn up ordinary characters in a Chinese dictionary. Finally, although Chinese is a monosyllabic and non-alphabetic language, a few attempts have been made and have been successfully carried out by a.d., by which the sound of any word can be indicated in a dictionary otherwise than by simply quoting a word of similar sound, which of course may be equally unknown to the reader. Thus, the sound of "a" and "e" are given in many Chinese articles, instead of two words, one having the initial ch, and the other a final ing. E.g. the sound ching is given as chien ling; that is chien fang-ching. The Concordance.—Considering the long unbroken series of years during which the Chinese literature has always kept copious on the whole, small gains in bulk, full, and is not astonishing to find such classical, historical, mythological and other allusions to personages or events of past times have also grown out of all proportion to the brain capacity given for such a rapid expansion, especially to meet this difficulty, there are several well-known handbooks, elementary and advanced, which trace such allusions to their source and provide full and lucid explanations; but even the most extensive of these dictionaries do not give the combinations of words, to be found in the classics, in the dynastic histories, and in all poets, historians, essayists, and writers of recognized eminence in their own lines. No attempt at explanation is given; but enough of the passage, or passages, in which the phrase occurs, is cited to enable the reader to gather the meaning required. The problem, of course, lies with the arrangement of these phrases in a non-alphabetic language. Recourse has been had to the Rhymes and Rhyme-words. The Chinese, it is true, are not a numerical people; but the same word form one of a number of groups which appear under the same Rhyme, the Rhymes themselves being distributed over five Tones. Thus, to find any phrase, the first point is to discover what is its Tone; the second is to find the group, and the third, the word itself. Then, under this Tone-group the Rhyme-word will be found, and under the Rhyme-word group will be found the final word of the phrase in question. It will now only remain to run through this last group, which is a human task, to catch the phrase. The result of such search—so vast is the collection—will usually yield a satisfactory result. The P'ei Wen Yen Fu runs of course to many volumes; a rough estimate shows it to contain over fifteen million words. This leaves the desire of having still more desired, yet, precise, information on a large variety of subjects, the Chinese may be said to have invented the encyclopedia. Though not the earliest work of this kind, the Tai Ping Yü Lan is the first of any great importance and the most lengthy. The work, the largest in the world, by a.d., under the direct supervision of the emperor, who is said to have examined three sections every day for about a year, the total number of sections being one thousand in all, arranged under fifty-five hundreds and each hundred into ten sections. The whole is divided into the following parts: (a) History, (b) Philosophy and (c) General Literature, including astronomy, geography, cosmogony, medicine, divination, Buddhism, Tassim, arts and handicrafts; and in 1408 such an encyclopedia was first printed, after the second edition, the text of which was copied and enlarged. It was named Yung Lo Ta Tien, or The Great Standard of Yung Lo. To compile this, 3 commissioners, with 5 directors, 20 sub-directors and a staff of 2141 assistants, had laboured for the space of five years. It consists of 1,110,000 pages, or sixty thousand sheets. Thirteen sections must be added an index filling 60 sections. Each section contained about 20 leaves, making a total of 917,480 pages for the whole work. Each page consisted of sixteen columns of characters averaging twenty-four characters to each, or a total of 366,992,000 characters, to which, in order to bring the amount into terms of English words, another third would have to be added. This extraordinary work was never printed, as the expense would have been too great, although it was actually transcribed for that purpose; and later on, two more copies were made, one of which was finally stored in Peking and the other, with the original, in Nanking. Both the Nanking copies perished at the fall of the Ming dynasty; and a similar fate overtook the Peking copy, with the exception of a few odd volumes, and this work is therefore known to have been in existence for a period of 11,100 volumes, covered with yellow silk, each volume being 1 ft. 8 in. in length by 1 ft. in breadth, and averaging over ½ in. in thickness. This work would perhaps be a fitting point to conclude any notice of this vast, indeed, all Chinese encyclopaedias, which for want of better equivalents may be roughly tended by (1) Heaven, (2) Earth, (3) Man, (4) Arts and Sciences, (5) Philosophy and (6) Political Science. These were subdivided into thirty-two classes, and the volume in each one accompanies to the further attempt was made to bring the scholar, with still closer touch with the individual items treated. Thus, the category Heaven is subdivided into four classes, namely, again, for want of better terms, (a) Astronomy and Mathematics and (b) Natural Phenomena. Under these three classes come the individual items; and here it is that the foreign student is often at a loss. For instance, class a includes all the phenomena relating to the direction of the heavens—that is, the position of the heavenly bodies and their motion. By contrast, the category Earth is subdivided into four classes, namely, (a) Geographical, (b) Geological, (c) Law, and (d) Literature. Under these phenomena relating to the categories of the planets and the stars. The remains of the ancient Chinese almanacs, which contain dates and times of eclipses of the other books, are the most important. The Chinese Almanac contains, as part of the contents, a tabulated list of eclipses of the Sun and Moon, the lunar, the lunar equinoxes and solstices, and the phases of the Moon. These tables are usually followed by a series of lengthy essays dealing with the subject as a whole, taken from the writings of qualified authors, and unlike all the other writings, also classified under a particular heading. About the same time, yet another and perhaps even more important work was begun, the Chinese Almanac. The actual work was done by the Jesuit Fathers employed by the emperor Kiang Hsi at Peking; also that only a hundred copies were struck off, the type being then destroyed. An 8vo edition of the whole encyclopaedia was issued at Peking during the reign of Queen Victoria. It consists of sixteen hundred and twenty-eight handsome volumes of about two hundred pages each. A copy of the original edition stands on the shelves of the British Museum, and a translation of the Index has recently been completed. Manuscripts and Printing.—At the conclusion of this brief survey of Chinese literature it may well be asked how such an encyclopaedic and other works have been handed down from generation to generation. According to the Chinese, the preservation of their works, under the care of early Chinese antiquarians, the first written records were engraved with a special knife upon bamboo slips and wooden tablets. The impracticability of such a process, as applied to books, never seems to have dawned upon those writers; and this snowball of error, started in the 7th century, long after the book and the tablet had disappeared as implements of writing, continued to gather strength as time went on. Recent researches, however, have placed it beyond doubt that when the Chinese began to write in a literary sense, as opposed to mere scratchings on branches, they traced their characters on slips of bamboo and tablets of wood with a bamboo pencil, frayed at one end to carry the coloured liquid which stood in the place of ink. The knife was used only to erase. So things went on until about 200 a.D., when it would appear that a brush of hair was substituted for the bamboo pencil; after which, silk was called into requisition as an appropriate vehicle in connexion with the more
delicate brush. But silk was expensive and difficult to handle, so that the invention of paper in A.D. 105 by a eunuch, named T'ai Chi, came as a great boon, although it seems clear that a certain kind of paper, made from silk, was in use far back, before this date. However that may be, from the 1st century onwards the Chinese have been in possession of the same writing materials that are in use at the present day.

In A.D. 170, T'ai Yung, who rose subsequently to the highest offices of state, wrote out on stone in red ink the authorized text of the Five Classics, to be engraved by workmen, and thus handed down to posterity. The work covered forty-six huge tablets, of which a few fragments are said to be still in existence. A similar undertaking was carried out in 837, and the later tablets are still standing at a temple in the city of Hsi-an Fu, Shensi. With the T'ang dynasty, rubbings of famous inscriptions, wherein the germ of printing may be detected, whether for the style of the composition or for the calligraphic excellence of the script, came very much into vogue with scholars and collectors.

It is also from about the same date that the idea of multiplying on paper impressions taken from wooden blocks seems to have arisen, chiefly in connexion with religious pictures and prayers. The process was not widely applied to the production of books until the 10th century, when in A.D. 932 the Confucian Canon was printed for the first time. In 981 orders were issued for the T'ai Ping Kuang Chi, an encyclopaedia extending to many volumes (see above) to be cut on blocks for printing. Movable types of baked clay are said to have been invented by an alchemist, named Pi Sheng, about A.D. 1041 and by the Ming dynasty, 1368-1644, these were made first of wood, and later of copper or lead, but movable types have never gained the favour accorded to block-printing, by means of which most of China's great typographical triumphs have been achieved. The process is, and always has been, the same all over China. Two consecutive pages of a book, separated by a column containing the title, number of section, and number of leaf, are written out and pasted face downwards on a block of wood (Lindera tsu-mu, Hems.). This paper, where not written upon, is cut away with sharp tools, leaving the characters in relief, and of course backwards, as in the case of European type. The block is then inked, and an impression is taken off, on one side of the paper only. This sheet is then folded down the middle of the separating column above mentioned, so that the blank halves come together, leaving two pages of printed matter outside; and when enough sheets have been brought together, they are stabbed at the open ends and form a volume, to be further wrapped in paper or pasteboard, and labelled with title, &c. It is almost superfluous to say that the pages of a Chinese book must not be cut. There is nothing inside, and, moreover, the column bearing the title and leaf-number would be cut through. The Chinese newspapers of modern times are all printed from movable types, an ordinary fount consisting of about six to seven thousand characters.

Giles, Chung Ts'ai (1898); A Chinese Biographer's Dictionary (1898), and A History of Chinese Literature (1901); A. Forbes, China's (1902); F. Hirth, The Ancient History of China (1908); L. Giles, Sun Tzu (1910). (H. A. G.)

CHINA, the common name for ware made of porcelain, given because it came from China, where the first vitrified, translucent, white ware was produced. The Portuguese or Italians gave it the name of "porcelain" (q.v.). English usage was influenced by India and the East, where the Persian chini was widely prevalent as the name of the ware. This is seen also in some of the earlier forms and pronunciations, e.g. chiney, chiney, and later chiney (see Ceramics); and for "china-clay" Kaulin.

CHINANDEGA, or Chinandega, the capital of the department of Chinandega in western Nicaragua, 10 m. N.N.E. of the seaport of Corinto by the Corinto-Managua railway. Pop. (1890) about 12,000. Chinandega is the centre of a fertile corn-producing district, and has a large transit trade owing to its excellent situation on the chief Nicaraguan railway. Its manufactures include coarse cloth, pottery and Indian feather ornaments. Cotton, sugar-cane and bananas are cultivated in the neighbourhood.

CHI-NAN Fu, the capital of Shan-tung, China, in 36° 48' N., 119° 17' E. Pop. about 100,000. It is situated in one of the earliest settled districts of the Chinese empire. The city, which lies in the valley of the present channel of the Yellow river (Hwang-Ho), and about 4 m. south of the river, is surrounded by a triple line of defence. First is the city wall, strongly built and carefully guarded, outside this granite wall, and beyond this again a mud rampart. Three springs outside the west gate throw up streams of tepid water to a height of about 2 ft. This water, which is highly prized for its healing qualities, fills the moat and forms a fine lake in the northern quarter of the city.

Chi-nan Fu was formerly famous for its manufacture of silks and of imitation precious stones. It is now the chief commercial entrepôt of Western Shan-tung but no longer a manufacturing centre. A highway connects it with the Yellow river, and it is joined by a railway 280 m. long to Kiao-chow. The city has a university for instruction on Western lines, and an efficient military school. American Presbyterians began mission work in the city in 1873; it is also the see of a Roman Catholic bishop.

CHINCHA ISLANDS, three small islands in the Pacific Ocean, about 12 m. from the coast of Peru (to which country they belong), opposite the town of Pisco, and 106 m. distant from Callao, in 13° 18' S., 76° 28' W. The largest of the group, known as the North Island or Isla del Norte, is only four-fifths of a mile in length, and about a third in breadth. They are of granitic formation, and rise from the sea in precipitous cliffs, worn into countless caves and hollows, which furnish convenient resting-places for the sea-fowl. Their highest points attain an elevation of 113 ft. The islands have yielded a few remains of the Chincha Indian race. They were formerly noted for vast deposits of guano, and its export was begun by the Peruvian government in 1830. The supply, however, was exhausted in 1874. In 1853-1854 the Chincha Islands were the chief object in a contest known as the Guano War between President Echenique and General Castilla; and in April 1864 they were seized by the Spanish rear-admiral Pinzon in order to bring the Peruvian government to apologize for its treatment of Spanish immigrants.

CHINCHEW, or Chinchehu, the name usually given in English charts to an ancient and famous port of China in the province of Fu-kien, of which the Chinese name is Ch'ien-chow-fu or T'sian-chow-fu. It stands in 24° 57' N., 118° 35' E. The walls have a circuit of 7 or 8 m., but embrace much vacant ground. The chief exports are tea and sugar, tobacco, china-ware, nankins, &c. There are remains of a fine mosque, founded by the Arab traders who resorted thither. The English Presbyterian Mission has had a chapel in the city since about 1862. Beyond the northern branch of the Min (several miles from the city) there is a suburb called Loyang, approached by the most celebrated bridge in China.

Ch'ien-chow, owing to the obstruction of its harbour by sand banks, has been supplanted as a port by Amoy, and its trade is carried on through the port of Nangan. It is still, however, a large and populous city. It was in the middle ages the great port of Western trade with China, and was known to the Arabs and to Europeans as Zaitilniya or Zayton, the name under which it appears in Abulfeda's geography and in the Mongol history of Rashiduddin, as well as in Ibn Batuta, Marco Polo and other medieval travellers. Some argument has been alleged against the identity of Zayton with Ch'ien-chow, and in favour of its being rather Changzhou (a great city 60 m. W.S.W. of Ch'ien-chow), or a port on the river of Changchow near Amoy. "Port of Zayton" may have embraced the great basin called Amoy Harbour, the chief part of which lies within the Fu or department of Ch'ien-chow; but there is hardly room for doubt that the Zayton of Marco Polo and Abulfeda was the Ch'ien-chow of the Chinese. Ibn Batuta informs us that a rich silk texture made here was called Zaitilniya; and there can be little doubt that this is the real origin of the word "Satim," Zettini in medieval Italian, Acetum in Spanish.
CHINCHILLA, a small grey hopping rodent mammal (Chin- 
cchilla langeri), of the approximate size of a squirrel, inhabiting
the eastern slopes of the Andes in Chile and Bolivia, at altitudes
between 8,000 and 12,000 ft. It typifies not only the genus
Chinchilla, but the family Chinchillidae, for the distinctive
features of which see Rodentia. The ordinary chinchilla is
about 10 in. in length, exclusive of the long tail, and in the form
of its head somewhat resembles a rabbit. It is covered with
a dense soft fur 3/4 in. long on the back and upwards of an inch
in length on the sides, of a delicate French grey colour, darkly
mottled on the upper surface and dusky white beneath; the ears
being long, broad and thinly covered with hair. Chinchillas
live in burrows, and these subterranean dwellings undermine
the ground in some parts of the Chilean Andes to such an extent
as to cause danger to travellers on horseback. They associate
in communities, forming their burrows among loose rocks, and
coming out to feed in the early morning and towards sunset.
They feed chiefly on roots and grasses, in search of which they
often travel considerable distances; and when eating they sit on
their haunches, holding their food in their fore-paws. The
Indians in hunting them employ the gun (Galliis iiuta), a
member of the weasel family, which is trained to enter the
crevices of the rocks where the chinchillas go the preceding
day. The flesh of this rodent was prized by the ancient
Peruvians, who made coverlets and other articles with the skin,
and at the present day the skins are exported in large numbers
to Europe, where they are made into muffes, tippets and trim-
nings. That chinchillas have not under such circumstances
become rare, if not extinct, is owing to their extraordinary
fecundity, the female usually producing five or six young twice
a year. They are docile in disposition, and thus well fitted for
domestication. The Peruvian chinchilla (C. brevicaudata)
being, with relatively shorter ears and tail; while still larger
species constitute the genus Lagidium, ranging from the Andes
to Patagonia, and distinguished by having four in place of five
front-toes, more pointed ears, and somewhat differently formed
skull. (See also Viscacha.)

CHINDE, a town of Portuguese East Africa, chief port for the
Zambesi valley and British Central Africa, at the mouth of the
Chinde branch of the Zambezi, in 18° 40'S., 36° 30'E. Pop.
(1907) 2799, of whom 218 were Europeans. Large steamers
are unable to cross the bar, over which the depth of water varies
from 10 to 18 ft. Chinde owes its existence to the discovery in 1889
that the branch of the river on the banks of which it is built is
navigable from the ocean (see ZAMBEZI). The Portuguese in
1891 granted on lease for 90 years an area of 5 acres—subse-
sequently increased to 25—to the British government, on which
goods in transit to British possessions could be stored duty
free. This block of land is known as the British Concession,
British Chinde. The prosperity of the town largely depends
on the transit trade with Nyasaland and North East Rhodesia.
There is also a considerable export from Portuguese districts,
sugar, cotton and ground nuts being largely cultivated in the
Zambezi valley, and gold and copper mines worked.

CHINDWIN, a river of Burma, the largest tributary of the
Irrawaddy, its entire course being in Burmese territory. It is
called Ningthi by the Manipurs. The Chindwin is formed by the
junction of the Tanai, the Tawan and the Tar in Turong,
but it is still uncertain which is the original name. It has
hitherto been looked on as the chief source. It rises in about
25° 30' N. and 97° E., on the Shwedaung-gyi peak of the Kumnón
range, 12 m. N. of Mogaung, and flows due N. for the first part
of its course until it reaches the Hukawng valley, when it turns
to the W. and flows through the middle of the plain to the end
of the valley proper. There it curves round to the S., passes
through the Tar in or Turong valley, takes the name of the
Chindwin, and maintains a general southerly course until it
enters the Irrawaddy, after flowing through the entire length
of the Upper and Lower Chindwin districts, in about 25° 30' N.
and 95° 15' E. Its extreme outlets are 22 m. apart, the interval
forming a succession of long, low, partially populated islands.
The most southerly mouth of the Chindwin is, according to
tradition, an artificial channel, cut by one of the kings of Pagan.
It was choked up for many centuries until in 1834 it was opened
by the Hukawng valley a Taping M. of S. of Saw; and joins or
receives the Tanai about 10 m. above Kintaw village. Except the
Tanai, the chief branches of the Upper Chindwin rise in mountains that
are covered at least with winter snows. Below the Hukawng valley
the Chindwin is intermittent in several places by falls or transverse reeds.
At the village of Halsa there is a fall, which necessitates tranship-
ment from large boats to canoes. Not far below this the Uyu river
comes in on the left bank at Homalin, and from this point down-
wards the stream may be said to form a part of the Irrawaddy. In the
dry season, it is navigable for a distance of 150 m. from its mouth by steamers of light draught.

CHINCHILLA—CHINESE PAVILLON
at most twice in a bar to punctuate the phrases and add brilliancy to the military music. The Turkish crescent or "jingling Johnny," as it was familiarly called in the British army bands, was introduced by the Janissaries into Western Europe. It has fallen into disuse now, having been replaced by the glockenspiel or steel harmonica. Edinburgh University possesses two specimens. In the 18th century at Bartholomew Fair one of the chief bands hired was one well known as playing in London on winter evenings in front of the Spring Garden coffee house and opposite Wigley’s. This band consisted of a double drum, a Dutch organ (see barrel-organ), a tambourine, a violin, pipes and the Turkish jingle.

CHINGFOR D—CHINO-JAPANESE WAR

K. S.

CHINGFOR D, an urban district in the Epping parliamentary division of Essex, England, 10½ m. N. of London (Lorke, 1901) 4373. It lies between the River Lea and the western outskirts of Epping Forest. The church of all Saints has early English and Perpendicular remains. Queen Elizabeth’s or Fair Meat hunting lodge, a picturesque half-timbered building, is preserved under the Epping Forest Preservation Act. A majestic oak, one of the finest trees in the Forest, stands near the Buckhurst Hill (an urban district; pop. 47,800) lies to the N.E. of the house.

CHINGLEPUT, or CHENNAI-PET, an urban district of British India, was a town of significance in the 17th century. The town, situated 36 m. by rail from Madras, had a population in 1901 of 10,528. With Chandragiri in North Arcot, Chingleput was once the capital of the Vijayanagar kings, after their overthrow by the Mussulmans at Talikota in 1565. In 1639 a chief, subject to these kings, granted to the East India Company the land on which Fort St. George now stands. The fort built by the Vijayanagar kings in the 16th century was of strategic importance, owing to its swampy surroundings and the lake that flanked its side. It was taken by the French in 1751, and was retaken in 1752 by Clive, after which it proved invaluable to the British, especially when Lally in his advance on Madras left it unretained in his rear. During the wars of the British with Hyder Ali it withstood its power, and afforded a refuge to the natives; and in 1780, after the defeat of Colonel W. Baillie, the army of Sir Hector Munro here found refuge. The town is noted for its manufacture of pottery, and carries on a trade in rice.

The District of Chingleput surrounds the city of Madras, stretching along the coast for about 115 m. The administrative head of the district is the town of Chingleput, with a pop. (1901) 1,312,122, showing an increase of 9% in the decade. Salt is extensively manufactured all along the coast. Cotton and silk weaving is also largely carried on, and there are numerous indigo vats, tanneries and an English cigar factory.

CHIN HILLS, a mountainous district of Upper Burma. It lies on the border between the Lushai districts of Eastern Bengal and Assam and the plains of Burma, and has an area of 8,000 sq. m. It is bounded N. by Assam and Manipur, S. by Arakan, E. by Burma, and W. by Tippera and the Chittagong hill tracts. The Chins, Lushais and Kukis are to the north-east border of India what the Pathan tribes are to the north-west frontier. In 1853 the Chin Hills were declared a province of the Burman, and constituted a scheduled district which is now administered by a political officer with headquarters at Falam. The tract forms a parallelogram 250 m. from N. to S. by 100 to 150 m. wide. The country consists of a much broken and contorted mass of mountains, intersected by deep valleys. The main range runs generally N. to S., and vary in height from 5000 to 9000 ft. In the southern sections lies the Letha or Tyang, which is the watershed between the Chindwin and Manipur rivers; the Imbhukkang, which divides the Sokte tribe from the Wenchens and sheds the water from its eastern slopes into Upper Burma and that from its western slopes into Arakan; and the Rongkang, which with its prolongations is the main watershed of the southern hills, its eastern slopes draining into the Mylitha and thus into the Chindwin, while the western fall drains into the

Boin river, which winds through the hills discharges itself eventually in the Bay of Bengal. The highest peak yet discovered is the Liklab, between Ramwy and Loungno, some 70 m. S. of Haka (nearly 10,000 ft.). It is supposed that the Kukis of Manipur, the Lushais of Bengal and Assam, and the Chins originally lived in Tibet and are of the same stock; their form of government, method of cultivation, manners and customs, and even their religious beliefs, all point to an affinity which is as unambiguous in the case of the Kukis as of the Chinese and Burman, and is as strongly marked in the case of the Lushai as of the Assam and Bengali. The Chin and Kuki languages belong to a different racial family from that of the Chinese and Burman. Their political organization is a strong argument for considering them as a distinct race, and their geographical position and their physical characteristics, as a strong argument for considering them as a distinct people. The Chins of Manburl are nearly related to the Chinese, but the Chins of Manip are more nearly related to the Kathiawar tribes of the Indian peninsula. The Chins of Arakan and of Upper Burma are related to the Assamese, and the Kukis of Manip to the Thais. The Chins were considered as a distinct race from the Chinese by the Chinese, and were not acknowledged by the Chinese as subjects. The Chinese exacted tribute money of the Chin and Kuki tribes of Upper Burma, but did not consider them as subjects. The Chinese of Manip acknowledged the Chinese as their superiors, and were considered as subjects by the Chinese. The Chinese of Arakan acknowledged the Chinese as their superiors, and were considered as subjects by the Chinese. The Chinese of Upper Burma acknowledged the Chinese as their superiors, and were considered as subjects by the Chinese.

CHINGKIAN, or CHIEN-Kiang-Fu, a treaty port of China, in the province of Kiang-su, on the Yangtsze-kiang above Shanghai, from which it is distant 160 m. It is in railway communication both with Shanghai and Nanking (40 m. distant), and being at the point where the Grand Canal running N. and S. intersects the Yangtsze, which runs E. and W., is peculiarly well situated to be a commercial entrepôt. The total value of exports and imports for 1904 was $4,632,902; estimated pop. 168,000. In the year 1842 it yielded to the British only after a desperate resistance. It was laid waste by the Taiping rebels in 1853, and was recaptured by the imperial forces in 1858.

CHINO-JAPANESE WAR (1894-95). The causes of this conflict arose out of the immemorial rivalry of China and Japan for influence in Korea. In the 16th century a prolonged war in the peninsula had ended with the failure of Japan to make good her footing on the mainland—a failure brought about largely by lack of naval resources. In more modern times (1875, 1882, 1884) Japan had repeatedly sent expeditions to Korea, and had extended the growth of a naval force in the Sea of Japan. The difficulties of 1884 were settled between China and Japan by the convention of Tientsin, wherein it was agreed that in the event of future intervention each should inform the other if it was decided to despatch troops to the peninsula. Nine years later the occasion arose. A serious rebellion induced the Korean government to apply for military assistance from China. Early in June 1894 a small force of Chinese troops were sent to Asan, and Japan, duly informed of this action, replied by furnishing her minister at Seoul with an escort, rapidly following up this step by the despatch of about 5000 troops under Major-General Oshima. A complicated situation thus arose. Chinese troops were present in Korea by the request of the government to put down rebellion. The Japanese controlled the capital, and declined to recognize Korea as a tributary of China. But she proposed that the two powers should unite to suppress the disturbance and to inaugurate certain specified reforms. China considered that the measures of reform must be left to Korea herself. The reply was that Japan considered the government of Korea incapable of taking independent action. The war was thus a "private war on the part of Japan, and an act of aggression on the part of Korea." By the middle of July war had become inevitable unless the Peking government were willing to abandon all claims over Korea, and as Chinese troops were already in the country by invitation, it was not to be expected that the shadowy suzerainty would be abandoned.

At Seoul the issue was forced by the Japanese minister, who delivered an ultimatum to the Korean government on the 20th of July. On the 23rd the palace was forcibly occupied. Meanwhile China had despatched about 8000 troops to the Yalu river.
The outbreak of war thus found the Japanese in possession of Seoul and ready to send large forces to Korea, while the Chinese occupied Asan (about 40 m. south of the capital), and had a considerable body of troops in Manchuria in addition to those despatched to the Yalu river. To Japan the command of the sea was essential for the secure transport and supply of her troops. Without it the experience of the war of the 16th century would be repeated. China, too, could only utilize overland routes to Korea by submitting to the difficulties and delays entailed. To both powers the naval question was thus important.

By the time war was finally declared (August 1) hostilities had already begun. On the 25th of July Oshima set out from Seoul to attack the Chinese at Asan. On the 29th he won a victory at Song-hwah. The Chinese commander escaped with what was left of his force by a rout to Ping-Yang (Phyng-Yang). Meanwhile a portion of the Japanese fleet had encountered some Chinese warships and transports off Phung-Tao, and scored an important success, sinks on their further vest, the gates of the Kawanada. The loss of more than 1000 Chinese soldiers in this vessel materially lightened Oshima’s task. The intention of the Chinese to crush their enemies between their forces at Asan and Ping-Yang was completely frustrated, and the Japanese obtained control of all the sea around Korea.

Reinforcements from Japan were now pouring into Korea, in spite of the fact that the rival navies had not yet tried conclusions, and General Nomo, the senior Japanese officer present, soon found himself in command of a large force and invested the place. A daring attack upon the place on the 15th of September, and in spite of its strong walls carried it, though only after severe fighting.

Nearly all the troops on either side had been conveyed to the sea coast, and the two sides fought a long and desperate battle for supremacy was still to be fought. The Chinese admiral Ting with the Northern Squadron (which alone took part in the war) had hitherto remained inactive in Wei-hai-wei, and on the other side Vice-Admiral Ito’s fleet had not directly interfered with the Chinese. Both fleets were reinforcing the troops on the Yalu. But two days after the battle of Ping-Yang, Ting, who had conveyed a large body of troops to the mouth of the Yalu, encountered the Japanese fleet on his way back to Wei-hai-wei, and the battle of Nogli’s (October 7th) was fought.

The heavy battleships “Chen-Yen” and “Ting-Yen” constituted the strongest element of the Chinese squadron, for, while they were in every other factor of success, had no vessels which could match these and which were equipped with more powerful guns. After a battle of two hours the Chinese ships were driven in a long irregular line abreast; the battleships in the centre, the lighter vessels on the wings. Ito’s fast cruisers steamed in line ahead against the Chinese right wing, crushing their weaker opponents with their fire. In the end the Chinese fleet was defeated and scattered, but the two heavy battleships drove off without serious injury. This battle of the Yalu gave Japan command of the sea, but Ito continued to act with great caution. The remnants of the Chinese fleet moved to Port Arthur, whence in the 11th and 12th of October fighting was renewed, but with little result. Ting proceeded to Wei-hai-wei.

The victory of Ping-Yang had cleared Korea of the Chinese troops, but on the lower Yalu—their own frontier—large forces threatened a sea attack on Liaotung. Ting, with the Southern Squadron (Yalu), under his 1st army, and on the 24th and 25th of October, under great difficulties—though without serious opposition from the enemy—forced the passage of the river and occupied Chihliien-cheng. Part of the Chinese force was seized on by his 2nd army, and advanced in a long irregular line abreast; the battleships in the centre, the lighter vessels on the wings. Ito’s fast cruisers steamed in line ahead against the Chinese right wing, crushing their weaker opponents with their fire. In the end the Chinese fleet was defeated and scattered, but the two heavy battleships drove off without serious injury. This battle of the Yalu gave Japan command of the sea, but Ito continued to act with great caution. The remnants of the Chinese fleet moved to Port Arthur, whence in the 11th and 12th of October fighting was renewed, but with little result. Ting proceeded to Wei-hai-wei.

The remnants of the Chinese fleet moved to Port Arthur, whence in the 11th and 12th of October fighting was renewed, but with little result. Ting proceeded to Wei-hai-wei.
three divisions converged on Niu-chwang port (Yiong-kow), and the final engagement took place at Tien-chwang-tai, which was captured on the 9th of March. The Chinese forces in Manchuria being thoroughly broken and dispersed, there was nothing to prevent the Japanese from proceeding to the occupation of Peking, since they could, after the break-up of the ice, land and surprise forces at Shahan-kwan, within 170 m. of the capital. Two more Japanese divisions were sent out, with Prince Komatsu as supreme commander. Seven divisions were at Port Arthur ready to embark, when the Americans and Russians renewed their attacks on the 21st of April. Li Hung-Chang proceeded to Shimonoseki, where the treaty was signed on the 17th of April 1895. An expedition was sent towards the end of March to the Pescadores, and later the Imperial Guard division was sent to Formosa.

It is estimated that 34,000 of the Japanese lost their lives in the war. The Chinese lost 4,777 men by death in action or by sickness, and 56,862 were wounded or disabled by sickness, exclusive of the losses in the Formosa and Pescadores expeditions. Nearly two-thirds were injured by the first army in the trying winter campaign in Manchuria.

**CHINON,** a town of western France, capital of an arrondissement in the department of Indre-et-Loire, on the right bank of the Vienne, 32 m. S.W. of Tours on the State railway. Pop. (1906) 4071. Chinon lies at the foot of the rocky eminence which is crowned by the ruins of the famous castle. Its narrow, winding streets contain many houses of the 15th and 16th centuries. The oldest of its churches, St Mexme, is in the Romanesque style, but only the façade and nave are Gothic. The church of St George is from the 11th century; that of St Maurice from the 12th, 13th and 16th centuries. The castle, which has undergone considerable modern restoration, consists of three portions. That to the east, the Château de St Georges, built by Henry II. of England, has almost vanished, only the foundation of the outer wall remaining. The Château du Millieu (11th to 15th centuries) comprises the keep, the Pavillon de l’Horloge and the Grand Logis, in the principal apartment of which the first meeting between Joan of Arc and Charles VII. took place. Of the Château du Coudray, which is separated from the Château du Millieu, the chief remains are the Tour du Moulin (10th century) and two less ancient towers. A statue of Rabelais, who was born in the vicinity, stands on the river-quay. Chinon has trade in wheat, brandy, red wine and plums. Basket and rope manufacture, tannin and cooperage are among its industries. Chinon (Cauno) existed before the Roman occupation of Gaul, and was from early times an important fortress. It was occupied by the Visigoths, and subsequently, after forming part of the royal domain, came to the counts of Touraine and from them to the counts of Anjou. Henry II. often resided in the castle, and died there. The place was taken by Philip Augustus in 1205, a year after the fall of *Chinook,* a tribe of North American Indians, dwelling at the mouth of the Columbia river, Washington. They were fishermen and traders, and used huge canoes of hollowed cedar trunks. The tribe is practically extinct, but the name survives in the trade language known as "Chinook jargon." This has been analysed as composed of two-fifths Chinook, two-fifths other Indian tongues, and the rest English and Canadian French; but the proportion of English has tended to increase. The Chinookan linguistic family includes a number of separate tribes.

The name CHINOK is also applied to a wind which blows from W. or N. over the slopes of the Rocky Mountains, where it descends as a dry wind warm in winter and cool in summer (cf. *Fohn*). It is due to a cyclone passing northward, and continues from a few hours to several days. It moderates the climate of the eastern Rockies, the snow melting quickly on account of its warmth and vanishing on account of its dryness, so that it is said to "lick up" the snow from the slopes.

**CHINURA,** a town of British India, on the Hugli river, 24 m. above Calcutta, formerly the principal Dutch settlement in Bengal. The Dutch erected a factory here in 1650, on a healthy spot of ground, much preferable to that on which Calcutta is situated. In 1759 a British force under Colonel Forde was attacked by the garrison of Chinura on its march to Calcutta, but in less than half an hour the Dutch were entirely routed. In 1795, during the Napoleonic wars, the settlement was occupied by a British garrison. At the peace of 1814 it was restored to the Dutch. It was among the cessions in India made by the king of the Netherlands in 1825 in exchange for the British possessions in Sumatra. Hugli College is maintained by government; and there are a number of schools, several of which are carried on by Scottish Presbyterian missionaries. Chinura is included in the Hugli municipality.

**CHINTZ,** a word derived from the Hindustani chint, spotted or variegated. This name was given to a kind of stained or painted calico produced in India. It is now applied to a highly glazed printed calico, commonly made in several colours on a light ground and used for bed hangings, covering furniture, &c.

**CHIOGGIA,** a town and episcopee of Venetia, Italy, in the province of Venice, from which it is 183 m. by sea. Pop. (1901) 21,384 (town), 31,218 (commune). It is inhabited mostly by fishermen, and is situated upon an island at the S. end of the lagoons. It is traversed by one main canal, La Vena. The peculiar dialect and customs of the inhabitants still survive to give it an2a distinct character.

**Naval War of Chioggia (1378-80).—**The naval war of 1378-1380, carried on by Venice against the Genoese and their allies, the lord of Carrara and the king of Hungary, is of exceptional interest as one in which a superior naval power, having suffered disaster in its home waters, and having been invaded, was yet able to win in the end by holding out till its squadrons in distant seas could be recalled for its defence.

When the war began in the spring of 1378, Venice was mainly engaged for the safety of its trading stations in the Levant and the Black Sea, which were exposed to the attacks of the Genoese. The more powerful of the two fleets which it sent out was despatched into the eastern Mediterranean under Carlo Zeno, the ballift of Chioggia, and again under Pietro Pisani in the western Mediterranean, and was placed under the command of Vettor Pisani. The possessions of Venice on the mainland, which were then small, were assailed by Francesco Carrara and his Hungarian allies. For a while both the Genoese of Genoa and the Venetians of Chioggia joined forces under Vettor Pisani, in a gale by 10 Venetian against 11 Genoese galleys. The Genoese admiral, Luigi de' Fieschi, was taken with 5 of his galleys, and others were wrecked. Four of the squadron escaped, and steered for Famagusta in Cyprus, then held by Genoese. If Pisani had directed his course to Genoa itself, which was thrown into a panic by the defeat at Anzio, it is possible that he might have dictated peace, but he thought his squadron too weak, and preferred to follow the Genoese galleys which had fled to Famagusta. During the summer of 1378 he was employed partly in attacking the enemy in Cyprus,
but mainly in taking possession of the Istrin and Dalmatian towns which supported the Hungarians from fear of the aggressive ambition of Venice. He was ordered to winter on the coast of Istrin, where his crews suffered from exposure and disease. Genoa, having recovered from the panic caused by his departure, sent out a small fleet at Carlo Zeno’s request while the rest of her ships were absent with Carlo Zeno. She sent a strong fleet into the Adriatic under Luciano Doria. Pisani had been reinforced early in the spring of 1375, but when he was sighted by the Genoese fleet of 25 sail off Pola in Istrin on the 9th of August he exercised a certain amount of caution in attacking them, and they were driven off. The Venetian admiral would have preferred to avoid battle, and to check an attack on Venice itself, by threatening the Genoese fleet from his base on the Istrin coast. He was forced into battle by the Genoese admiral Pietro Doria, which was decisive. The Venetian commandant of the senate had authority over the admiral. The Venetians were defeated with the loss of all their galleys except six. Luciano Doria fell in the battle, and the Genoese, who had suffered severely, did not pursue their opponents. Their admiral, Pieterus Abbas, the successor of Pietro Doria, with reinforcements, they appeared off the Lido, the outer barrier of the lagoon of Venice, in July, and in August they entered on a combined naval and military attack on the city. The combined movements of the Genoese and their Venetian allies, and the Venetian admiral’s intention to occupy the island of Brondolo, was seen by the Lido, which was garrisoned with 3,000 men.

There appeared to be nothing to prevent the enemy from advancing to the city of Venice except the difficult navigation of the lagoon. The Venetian authorities, led by Carlo Zeno, who was in command of the fleet, were resolved to “bit and bridle the horses of Saint Mark” the Venetians decided to fight to the end. Vettor Pisani, who had been imprisoned after the defeat at Pola, who possessed the confidence of the Senate and the command of the fleet, and named commander-in-chief against the wish of the aristocracy. Under his guidance the Venetians adopted a singularly bold and ingenious policy of offensive defense. The heavy Genoese vessels could not come in close enough to the shore to heap destruction on their own vessels behind the lagoon. By taking advantage of their embodiment and his own local knowledge, Pisani carried out a series of movements which entirely turned the tables on the invaders. Between the 23rd and 29th of August he exercised a movement of the Genoese with their vessels laden with stores not only in the canals leading through the lagoon to Venice, but in the canals leading from Chioggia to the open sea round both ends of the island of Brondolo. The Genoese vessels were driven away and their vessels were forced to hold the shore to prevent the Venetians from kissing the shores of the lagoon. By taking an oath not to return to Venice they had recovered Chioggia. Carlo Zeno had long since been ordered to return, but the slowness and difficulty of the route through the canal and of the Genoese vessels made him change his mind. At this point the Venetians were able to reconquer Chioggia.

The besiegers of Chioggia were at the end of their powers of endurance, and Pisani had been compelled to give a promise that the siege would be raised, when Zeno’s fleet reached the anchorage off Brondolo on the 1st of January 1380. The attack on the island was now pressed with vigour. The Genoese held out resolutely in the hope of relief from home. But the resources of Genoa had been taxed to pay the mercenaries who were still in Italy, and it was not long before the Venetian fleet was able to reach the neighbourhood of Brondolo with a relieving force. By this time the Venetians had recovered the island, and their fleet occupied a fortified anchorage from which they refused to be driven. The strategic role of the island was pronounced by the presence of the defenders of Chioggia surrendered. The crisis of the war was past. Venice, being now safe at home, recovered the command of the sea, and before the close of the year was able to make peace as a consequence.

**CHIOS.** An island on the west coast of Asia Minor, called by the Greeks Chios (Χίος, χίον) and by the Turks Saki Ada; the soft pronunciation of X before a in modern Greek, approximating to sh, causes the Greek Χίος to be changed to sh, as in English forms, with the island of the east of Asia Minor, Nicaria, Leros, Calymnos, and Cos, a sannuk of the Archipelago vilajet. Chios is about 30 m. long from N. to S., and from 8 to 15 m. broad; pop. 64,000. It well deserves the epithet "craggy" (κραγκωσσα) of the Homeric hymn. Its figs were noted in ancient times, but wine and gum mastic have always been the most important products. The climate is healthy. Oranges, olives and even palms grow freely. The mastic, a gum, is grown on the N.W. coast, in the district called by Strabo Ariasion, was known as *vinnum Arisium.* Early in the 7th century B.C. Glauceus of Chios discovered the process of deadling mastic (οδοκρανια: see J. G. Frazer’s “Pausanias,” note on x. 16, 1). The iron stand of a large scythe, which parts were all connected by this process was constructed by him, and preserved as one of the most interesting relics of antiquity at Delphi. The long line of Chian sculptors (see Greek Art) in marble bears witness to the fame of Chian Art. In literature the chief glory of Chios was the school of epic poets called Homeridae, who helped to create a received text of Homer and gave the island the reputation of being the poet’s birthplace. The chief town, Chios (pop. 16,000), is on the E. coast. A theatre and a temple of Athena Poliuchus existed in the ancient city. About 6 m. N. of the city there is a curious monument of antiquity, commonly called the “school of Homer”; it is a very ancient sanctuary of Cybele, with an altar and a figure of the goddess with her two lions, cut out of the native rock on the summit of a hill. Other the west coast there is a temple dedicated to Artemis, built by Constantine IX. Monomachus (1042-1055). Starting from the city and encompassing the island, one passes in succession the promontory Posidium; Cape Phanace, the southern extremity of Chios, with a harbour and a temple of Apollo; Notium, probably the south-western point of the island; Laii, opposite the city of Chios, where the island is narrowest; the town Bolissus (now Volissos), the home of the Homerid poets; Melaena, the north-western point; the wine-growing district Ariusia; Cardamylo (now Cardhamili); the north-eastern promontory was probably named Phium, and the mountains that cross the northern part of the island Pelinaeus or Pellenaeus.

The history of Chios is very obscure. According to Pherecydes, the original inhabitants were Leleges, while according to other accounts Thessalian Pelasgi possessed the island before it became an Ionian state. The name Aethalos, common to Chios and Lemnos in very early times, suggests the original existence of a homogeneous population in these and other neighbouring islands. Oenopion, a mythical hero, son of Dionysus or of Rhadamnthus, was an early king of Chios. His successor in the fourth generation, Hector, united the island to the Ionian confederation (Paus. vii. 4); though Strabo (ibid. p. 633) implies a powerful state. The loyal state was at a later time exchanged for an oligarchy or a democracy. The names of two tyrants, Amphilochus and Polyclemus, are mentioned. The products of the island were largely exported on the Black Sea, and as early as the beginning of the 7th century B.C. the alliance in opposition to the rival league of Phocaea and Samos. Similar commercial considerations determined the Chians in their attitude towards the Persian conquerors; in 546 they submitted to Cyrus, or trading companies, which was organized in 1340, opened their fleet of 100 sail joined the Milesians in offering a desperate opposition at Lade (494). The island was subsequently punished with great rigour by the Persians. The Chian ships, under the tyrant Strato, continued to exercise an air in Asia Minor. In 475 Chios joined the Delian League and long remained a firm ally of the Athenians, who allowed it to retain full autonomy. But in 413 the island revolted, and was not recaptured. After the Peloponnesian War, Chios (1380) was recovered by the Doria family but in 357 again seceded. As a member of the Delian League it had regained its prosperity, being able to equip a fleet of 50 or 60 sail. Moreover, it was reputed one of the best-governed states in Greece, for the prosperity of the state depended largely on the influence of the Mohammedans. Neither party persecuted the other severely. It was not till late in the 4th century that civil dissension became a danger to the state, leaving it a prey to Idriceus, the dynasty of Caria (346), and to the Persians under the Magistros. After a long struggle the Chians maintained itself in a virtually independent position. It supported the Romans in their Eastern wars, and was called a “free and allied state.” Under Roman and Byzantine rule industry and commerce were undisturbed, its chief export at this time being the Arvisium wine, which had been the subject of special taxation by the Seljuk Turks (1082-1092) and by the Venetians (1124-1125, 1172, 1204-1225), it was given in fief to the Genoese family of Zaccaria, and in 1346 passed definitely into the hands of a Genoese company, which was organized in 1340, under the name of “the Giustinian.” This mercantile brotherhood, formerly a privileged class, alone exploited the mastic trade; at the same time the Greeks were allowed to retain their rights of self-government and continue their own administration. In 1415 the Genoese became tributary to the Ottomans. In spite of occasional secessions
which brought severe punishment upon the island (1453, 1479), the rule of the Giustiniani was not abolished till 1566. Under the Ottoman government the prosperity of Chios was hardly affected. But the island underwent severe periods of suffering after its capture and reconquest from the Florentines (1595) and the Venetians (1694-1665), which greatly reduced the number of the Latins. Worst of all were the massacres of 1822, which followed upon an attack by some Greek insurgents executed against the will of the natives. In 1881 Chios was visited by a very severe earthquake in which their houses and more than half the villages were seriously damaged. The island has now recovered its prosperity. There is a harbour at Castro, and steam flour-mills, foundries and tanneries have been established. Rich antiquity and calamine mines are worked for a French undertaking, and good marble is quarried by an Italian company.

CHIPPENDALE, THOMAS (d. 1779), the most famous of English cabinet-makers. The main source for the biography of Chippendale are extremely scanty, but lie is known to have been the son of Thomas Chippendale, and is believed to have been the father of Thomas Chippendale III. His father was a cabinet-maker and wood-carver of considerable repute in Worcester, and in the beginning of the 18th century, and possibly he originated some of the forms which became characteristic of his son’s work. Thus a set of chairs and settles was made, apparently at Worcester, for the family of Bury of Knateshills, at a period when the great cabinet-maker could have been no more than a boy, which are practically identical with much of the work that was being turned out of the family factory as late as the sixties of the 18th century. Side by side with the Queen Anne or early Georgian feeling of the first quarter of the 18th century we find the interlaced splats and various other details which marked the Chippendale style. By 1729 the elder Chippendale and his son had removed to London, and at the end of 1749 the younger man—his father was probably then dead—established himself in Conduit Street, Long Acre, whence in 1753 he removed to No. 62 St. Martin’s Lane, which with the addition of the adjoining three houses formed the centre of his business. In 1762 his workshops were burned down; in 1766 he was elected a member of the Society of Arts; in 1776 his partnership with James Rann was dissolved by the latter’s death.

It has always been exceedingly difficult to distinguish the work executed in Chippendale’s factory and under his own eye from that of the many copyists and adapters who throughout the second half of the 18th century—the golden age of English furniture—plundered remorselessly. Apart from his published designs, many of which were probably never made up, we have to depend upon the very few instances in which his original accounts enable us to earmark work which was unquestionably his. For Claydon House, the seat of the Verneys in Buckinghamshire, he executed much decorative work, and the best judges are satisfied that the Chinese bedroom there was designed by him. At Harewood House, the seat of the earl of Harewood in Yorkshire, we are on firmer ground. The house was furnished between 1765 and 1771, and both Robert Adam and Chippendale were employed upon it. Indeed, there is unmistakable evidence that Chippendale was engaged in work, so closely characteristic of his style that it might have been assigned to them without hesitation, was actually produced by Chippendale. This may be another of the many indications that Chippendale was himself an imitator, or it may be that Adam, as architect, prescribed designs which Chippendale’s cabinetmakers and carvers executed. Chippendale’s bills for this Adam work are still preserved. Stourhead, the famous house of the Hoares in Wiltsire, contains much undoubted Chippendale furniture, which may, however, be the work of Thomas Chippendale III; at Rowton Castle, Shropshire, Chippendale’s bills as well as his works still exist.

Our other main source of information is The Gentleman and Cabinet Maker’s Director, which was published by Thomas Chippendale in 1754. This book, the most important collection of furniture designs issued up to that time in England, contains one hundred and sixty engraved plates, and the list of subscribers indicates that the author had acquired a large and distinguished body of customers. The book is of folio size; there was a second edition in 1759, and a third in 1762.

In the rather bombastic introduction Chippendale says that he has been encouraged to produce the book “by persons of distinction and taste, who have regretted that an art capable of so much perfection and refinement should be executed with so little propriety and elegance.” He has some severe remarks upon critics, from which we may assume that he had already suffered at their hands. Perhaps, indeed, Chippendale may have been hinted at in the caustic remarks of Isaac Ware, surveyor to the king, who bewailed that it was the misfortune of the world in his day “to see an unmeaning scrawl of C’s inverted and looped together, taking the place of Greek and Roman elegance even in our most expensive decorations. It is called French, and let them have the praise of it! The Gothic shaft and Chinese bell are not beyond nor below it in poorness of imitation.” It is the more likely that these barbs were intended for Chippendale, since he was guilty not only of many essays in Gothic, but of a very large number of rococo works, some of which show the flamboyant style of Louis XV.

The Director contains examples of all the manners which aroused the scorn of the king’s surveyor. Chippendale has even shared with Sir William Chambers the obloquy of introducing the Chinese style, but he appears to have done nothing worse than “conquer,” as Alexandre Dumas used to call it, the ideas of other people. Nor would it be fair to the man who, whatever his occasional extravaganzas and absurdities, was yet a great designer and a great transmuter, to pretend that all his Chinese designs were contemptible. Many of them, with their geometrical lattice-work and carved tracery, are distinctly elegant and effective. Occasionally we find in one piece of furniture a combination of the three styles which Chippendale most affected at different periods—Louis XV., Chinese and Gothic—and it cannot honestly be said that the result is as incongruous as might have been expected. Some of his most elegant and attractive work is derived directly from the French, and we cannot doubt that the inspiration of his famous ribbon-backed chair came directly from something more or less of this character.

The primary characteristic of his work is solidity, but it is a solidity which rarely becomes heaviness. Even in his most lightsome efforts, such as the ribbon-backed chair, construction is always the first consideration. It is here perhaps that he differs most materially from his great successor Sheraton, whose ideas of construction were eccentric in the extreme. It is indeed in the chair that Chippendale is seen at his best and most characteristic. From his hand, or his pencil, we have a great variety of chairs, which, although differing extensively in detail, may be roughly arranged in three or four groups, which it would sometimes be rash to attempt to date. He introduced the cabriole leg, which, despite its antiquity, came immediately from Holland; the claw and ball foot of ancient Oriental use; the straight, square, uncompromising early Georgian leg; the carved lattice-work Chinese leg; the pseudo-Chinese leg; the fretwork leg, which was supposed to be in the best Gothic taste; the inlaid rococo leg with the curled or hoofed foot; and even occasionally the spade foot, which is supposed to be characteristic of the somewhat later style of Hepplewhite. His chair-backs were very various. His efforts in Gothic were sometimes highly successful; often they took the form of the tracery of a church window, or even of an ovalled rose window. His Chinese backs were distinctly geometrical, and from them he would seem to have derived some of the inspiration for the frets of the glazed bookcases and cabinets which were among his most agreeable work. The most attractive feature of Chippendale’s most artistic chairs—those which, originally derived from Louis Quinze models, were deprived of their rococo extravagances—is the back, which, speaking generally, is the most elegant and pleasing thing that has ever been done in furniture. He took the old solid or slightly pierced back, and cut it up into a light openwork design.
exquisitely carved—for Chippendale was a carver before everything—in a vast variety of designs ranging from the elaborate and extremely elegant, if much criticized, ribbon back, to a comparatively plain but highly effective splat. His armchairs, however, often had solid or stuffed backs. Next to his chairs Chippendale was most successful with settees, which almost invariably took the shape of two or three conjoined chairs, the arms, backs and legs identical with those which he used for single seats. He was likewise a prolific designer and maker of bookcases, cabinets and escritoires with doors glazed with fretwork divisions. Some of those which he executed in the style which in his day passed for Gothic are exceedingly handsome and effective. We have, too, from his hand many cases for long clocks, and a great number of tables, some of them with a remarkable degree of Gallic grace. He was especially successful in designing small tables with fretwork galleries for the display of china. His mirrors, which were often in the Chinese taste or extravagantly rococo, are remarkable and characteristic. In his day the cabinetmaker still had opportunities for designing and constructing the four-post bedstead, and some of Chippendale's most graceful work was lavished upon the woodwork of the lighter, more refined and less monumental four-poster, which, thanks in some degree to his initiative, took the place of the medieval bed. He was a master of the organ case to a wash-hand-stand, indeed, no piece of domestic furniture came amiss to this astonishing man, and if sometimes he was extravagant, grotesque or even puerile, his level of achievement is on the whole exceedingly high.

Since the revival of interest in his work he has often been criticized with considerable asperity, but not always justly. Chippendale's work has stood the supreme test of posterity more completely than that of any of his rivals or successors; and, unlike many men of genius, we know him to have been warmly appreciated in his lifetime. He was at once an artist and a prosperous man of business. His claims to distinction are summed up in the fact that his name has by general consent been attached to the most splendid period of English furniture.

Chippendale was buried on the 13th of November 1779, apparently at the church of St Martin-in-the-Fields, and administration of his intestate estate was granted to his widow Elizabeth. He left four children, Thomas Chippendale III., John, Charles and Mary. He was one of the assignees in bankruptcy of the notorious Theresa Cornelys of Soho Square, of whom we read in Chicago's "Chippendale House", an old book, by the Miss Amy Burhred, who maintained that Thomas Chippendale III. succeeded to the business of his father and grandfather, and for some years the firm traded under the style of Chippendale & Haig. The factory remained in St Martin's Lane, but in 1814 an additional shop was opened at No. 57 Haymarket, whence it was in 1821 removed to 42 Jermy Street. Like his father, Thomas Chippendale III. was a member of the Society of Arts; and he is known to have exhibited five pictures at the Royal Academy between 1784 and 1801. He died at the end of 1822 or the beginning of 1823. (J. P.-B.)

CHIPPENHAM, a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, England, 94 m. W. of London by the Great Western railway. Pop. (1907) 5074. Chippenham is governed by a mayor, 4 aldermen and 12 councillors. Area, 361 acres. It lies in a hollow on the south side of the Upper Avon, here crossed by a picturesque stone bridge of 21 arches. St Andrew's church, originally Norman of the 12th century, has been enlarged in different styles. A paved causeway running for about 4 m. between Chippenham Cliff and Wick Hill is named after Maud Heath, said to have been a market-woman, who built it in the 15th century, and bequeathed an estate for its maintenance. After the decline of its woolen and silk trades, Chippenham became celebrated for grain and cheese markets. There are also manufactures of broadcloth, chins, condensed milk, railway-signals, guns and carriages; besides bacon-curing works, flour mills, tanneries and large stone quarries. Bowood, the seat of the marquis of Lansdowne, is 31 m. S.E. of Chippenham. Lanhill barrow, or Hubba's Low, 24 m. N.W., is an ancient tomb containing a kistvaen or sepulchral chamber of stone; it is probably British, though tradition makes it the grave of Hubba, a Danish leader.

Chippenham (Chesham, Chippenham) was the site of a royal residence where in 853. Æthelwulf celebrated the marriage of his daughter Æthelwitha with Burhred, king of Mercia. The town also figured prominently in the Danish invasion of the 9th century, and in 933 was the meeting-place of the witan. In the Domesday Survey Chippenham appears as a crown manor and is not assessed in hides. The town was governed by a bailiff in the reign of Edward I., and returned two members to parliament from 1295, but it was not incorporated until 1553, when a charter from Mary established a bailiff and twelve burgesses and endowed the corporation with certain lands for the maintenance of two parliamentary burgesses and for the repair of the bridge over the Avon. In 1684 this charter was surrendered to Charles II., and in 1685 a new charter was received from James II., which was shortly abandoned in favour of the original grant. The Representation Act of 1868 reduced the number of parliamentary representatives to one, and the borough was disfranchised by the Redistribution Act of 1885. The derivation of Chippenham from _cyppan_, to buy, implies that the town possessed a market in Saxon times. When Henry VII. introduced the clothing manufacture into Wiltshire, Chippenham became an important centre of the industry, which has lapsed. A prize, however, was awarded to the town for this commodity at the Great Exhibition of 1851.

CHIPPEWA FALLS, a city and the county-seat of Chippewa county, Wisconsin, U.S.A., on the Chippewa river, about 100 m. E. of St Paul, Minnesota, and 12 m. N.E. of Eau Claire, Wisconsin. Pop. (1890) 8670; (1900) 8044; (1910, census) 8583. It is served by the Minneapolis, St Paul & Sault Ste Marie, the Chicago & North-Western, and the Chicago, Milwaukee & St Paul railways, and by the electric line to Eau Claire. The first settlement on the site was made in 1837; and the city was chartered in 1870.

CHIPPING CAMPDEN, a market town in the northern parliamentary division of Gloucestershire, England, on the Oxford and Worcester line of the Great Western railway. Pop. (1901) 1542. It is picturesquely situated towards the north of the Cotteswold hill-district. The many interesting ancient houses afford evidence of the former greater importance of the town. The church of St James is mainly Perpendicular, and contains a number of brasses of the 15th and 16th centuries and several notable monumental tombs. A ruined manor house of the 16th century is complete, with the church, a picturesque group of buildings, and Campden House, also of the 16th century, deserves notice.

Apart from a medieval tradition preserved by Robert de Brunne that it was the meeting-place of a conference of Saxon kings, the earliest record of Campden (Campedene) is in Domesday Book, when Earl Hugh is said to hold it, and to have there fifty villeins. The number shows that a large village was attached to the manor, which in 1173 passed to Hugh de Gondeville, and about 1204 to Ralph, earl of Chester. The borough must have grown up during the 12th century, for both these lords granted the burgesses charters which are known from a confirmation of 1247, granting that they and all who should come to the market of Campeden should be quit of toll, and that if any free burgess of Campeden should come into the lord’s amerciament he should be quit for 1 2d. unless he should shed blood or do felony. Probably Earl Ralph also granted the town a portmante, for the account of a skirmish in 1273 between the men of the town and the county mentions a bailiff and implies the existence of some sort of municipal government. In 1605 Campeden was incorporated, but it never returned representatives to parliament. Campden still speaks of the town as a market famous for stockings, a relic of that medieval importance as a mart for wool that had given the town the name of Chipping.

CHIPPERWICK, a market town and municipal borough in the Barbury parliamentary division of Oxfordshire, England, 26 m. N.W. of Oxford by a branch of the Great Western railway.

1 For the Chippewa Indians see Ojibway, of which the word is a popular adaptation.
Pop. (1901) 3780. It lies on the steep flank of a hill, and consists mainly of one very wide street. The church of St Mary the Virgin, standing on the lower part of the slope, is a fine building of the Decorated and Perpendicular periods, the polygonal porch and the clerestory being good examples of the later style. The town has woollen and glove factories, breweries and an agricultural trade. It is governed by a mayor, 4 aldermen and 12 councillors. Area, 2456 acres. Chipping Norton (Chepyng-
norton) was probably of some importance in Saxon times. At the Domesday Survey it was held in chief by Ernulf de Hesiding; it was assessed at fifteen hides, and comprised three mills. It returned two members to parliament as a borough in 1302 and 1304-1305, but was not represented after this date, and was not considered to be a borough in 1376. The first and only charter of incorporation was granted by James I., in 1603; it established a common council consisting of 2 bailiffs and 12 burgesses; a common clerk, 2 justices of the peace, and 2 serjeants-at-mace; and a court of record every Monday. In 1205 William Fitz-Alan was granted a four days’ fair at the feast of the Invention of the Cross; and in 1376 Roger, earl of March, was granted a four days’ fair at the feast of St Barnabas. In the reign of Henry VI. the market was held on Wednesday, and a fair was held at the Translation of St Thomas Becket. These continued to be held in the reign of James I., who annulled the former two fairs, and granted fairs at the feasts of St Mark, St Matthew, St Bartholomew, and SS. Simon and Jude.

CHIQUITOS (Span. “very small”), a group of tribes in the province of Santa Cruz de la Sierra, Bolivia, and between the head waters of the rivers Mamoré and Itenez. When their country was first invaded they fled into the forests, and the Spaniards, coming upon their huts, the doorways of which are built excessively low, supposed them to be dwarfs: hence the name. They are in fact well formed and powerful, of middle height and of an olive complexion. They are an agricultural people, but made a gallant resistance to the Spaniards for nearly two centuries. In 1691, however, they made the Jesuit missionaries welcome, and rapidly became civilized. The Chiquito language was adopted as the means of communication among the converts, who soon numbered 50,000, representing nearly fifty tribes. Upon the expulsion of the Jesuits in 1767 the Chiquitos became decadent, and now number about 20,000. Their houses, regularly ranged in streets, are built of adobe thatched with grass roof. They manufacture copper boilers for making sugar and understand several trades, weave ponchos and hammocks and make straw hats. They are fond of singing and dancing, and are a gentle-mannered and hospitable folk. The group is now divided into forty tribes.

CHIROMANCY (from Gr. χειρ, hand, and μανώς, divination), the art of telling the character or fortune of persons by studying the lines of the palms of the hands (see PALMISTRY).

CHIRON, or CHEIRON, in Greek mythology, one of the Centaurs, the son of Cronus and Philyra, a sea nymph. He dwelt at the foot of Mount Pelion, and was famous for his wisdom and knowledge of the healing art. He offers a remarkable contrast to the other Centaurs in manners and character. Many of the most celebrated heroes of Greece were brought up and instructed by him (Apollodorus iii. 10. 13). Accidentally pierced by a poisoned arrow shot by Heracles, he renounced his immortality in favour of Prometheus, and was placed by Zeus among the stars as the constellation Sagittarius (Apollodorus ii. 5; Ovid, Fasti, v. 414). In a Pompeian wall-painting he is shown teaching Achilles the lyre.

CHIROPIDIST (an invented word from Gr. χεῖρ, hand, and πόδος, foot), properly one who treats the ailments of the hands and feet, or is consulted as to keeping them in good condition; the use of the word is now restricted, however, to the care of the toes, “manicurist” having been invented for the corresponding attentions to the fingers. The word was first introduced in 1785, by a “corn-cutter” in Davies Street, London.

CHIROPTERA (Greek for “hand-wings”), an order of mammals containing the bats, all of which are unique in the class in possessing the power of true flight, and have their fore-limbs specially modified for this purpose.

The mammals comprised in this order are at once distinguished by the possession of true wings; this peculiarity being accompanied by other modifications of bodily structure having relation to aerial locomotion. Thus, in direct contrast to all other mammals, in which locomotion is chiefly effected by action from behind, and the hind-limbs consequently greatly preponderate in size over the fore, in the Chiroptera the fore-limbs, being the agents in propelling the body forward during flight, immensely exceed the short and weak hinder extremities. The

Thorax, giving origin to the great muscles which sustain flight, and containing the proportionately large lungs and heart, is remarkably capacious; and the ribs are flattened and close together; while the shoulder-girdle is greatly developed in comparison with the weak pelvis. The fore-arm (fig. 1) consists of a rudimentary ulna, a long curved radius, and a carpus of six bones supporting a thumb and four elongated fingers, between which, the sides of the body, and the hinder extremities a thin expansion of skin, the wing-membrane, is spread. The knee is directed backwards, owing to the rotation of the hind-limb, onwards by the wing-membrane; an elongated cartilaginous process (the calcip), rarely rudimentary or absent, arising from the inner side of the ankle-joint, is directed inwards, and supports part of the posterior margin of an accessory membrane of flight, extending from the tail or posterior extremity of the body to the hind-limbs, and known as the inter-femoral membrane. The penis is pendent; the testes are abdominal or inguinal; the teats, usually two in number, thoracic; the uterus is simple or with more or less long cornua; the placenta discoidal and deciduate; and the smooth cerebral hemispheres do not extend backwards over the cerebellum. The teeth comprise incisors, canines, premolars and molars; and the dental formula never
CHIROPTERA

exceeds $i,$ $t,$ $c,$ $\frac{1}{2},$ $p,$ $\frac{3}{2},$ $m,$ $\frac{3}{2};$ total 38. Despite the forward position of the teats, which is merely an adaptive feature, bats are evidently mammals of low organization, and are most nearly related to the Insectivora.

In consequence of the backward direction of the knee, a bat, when placed on the ground, rests on all fours, having the knees directed upwards, while the foot is rotated forwards and inwards on the ankle. Walking is thus a kind of shuffle; but, notwithstanding a general belief, bats can take wing from the walking posture.

The bones of the skeleton are characterized by their slenderness and the great size of the medullary canals in those of the extremities. The vertebral column is short, and the vertebrae differ but slightly in number and form throughout the group. The general number of dorso-lumbar vertebrae is 17, whereas 12 are dorsal; the cervical vertebrae are broad, but short. Except in fruit-bats (Pteropodidae), the vertebrae, from the third cervical backwards, are devoid of spinous processes. From the first dorsal to the last lumbar the vertebral column forms a single curve, most pronounced in the lumbar region. The bodies of the vertebrae are but slightly movable on each other, and in allied individuals become partially welded. The caudal vertebrae are cylindrical bones without processes; their number and length varying in allied species. The development of these vertebrae is correlated with habits, the long tail in the insectivorous species supporting and controlling the position of the interfemoral membrane which aids bats in their doubling motions when in pursuit of insects by acting as a rudder, and assists them in the capture of the larger insects. In the fruit-bats this is not required, and the tail is rudimentary or absent. In all bats the pre sternum has a prominent keel for the attachment of the great pectoral muscles.

The shape of the skull varies greatly; but post-orbital processes are developed only in some Pteropodidae and a few Nycteridae and Emballonuridae; in Pteropus leucotis alone does a process from the zygomatic arch meet the post-orbital so as to complete the orbital ring. Zygomatic arches, though slender, are present in all except in some of the species of Phyllostomatidae.

The milk-teeth differ from those of all other mammals in that they are unlike those of the permanent series. They are slender, with pointed roots, recurved, and are crowded in the milk-teeth a short time with the permanent teeth. In the Rhinolophidae the milk-teeth are absorbed before birth. The permanent teeth exhibit great variety, sometimes even in the same family, as in Phyllostomatidae, whilst in other families, as Rhinolophidae, the resemblance between the dentition of species differing in many respects is remarkable. In all they are provided with well-developed roots, and their crowns are acutely tuberculate, with more or less well-defined W-shaped cusps, in the insectivorous species, or variously hollowed out or longitudinally grooved in the frugivorous kinds.

The shoulder-girdle varies but slightly, the clavicle being long, strong and curved; and the scapula large, oval and triangular, with a long curved coracoid process. The humerus, though long, is scarcely two-thirds the length of the radius; and the rudimentary ulna is welded with the radius. A sesamoid bone exists in the tendon of the triceps muscle. The upper row of the carpus consists of the united scaphoid, lunar and cuneiform bones.

The "hand" has five digits, the first, fourth and fifth of which consist each of a metacarpal and two phalanges; but in the second and third the number of phalanges is different in certain families. The first digit terminates in a claw, most developed in the frugivorous species, in most of which the second digit is also clawed, although in other bats this and the remaining digits are unarmed.

In the weak pelvis the ilia are long and narrow, while in most species the pubes of opposite sides are loosely united in front in males, and widely separated in females; in the Rhinolophidae alone they form a symphysis. Only in the Molossinae is there a well-developed fibula; in the rest this bone is either very slender or cartilaginous and ligamentous in its upper third, or reduced to a small bony process above the heel, or absent. The foot consists of a short tarsus, and of slender, laterally compressed toes, with much-curved claws.

Although the brain is of a low type, probably no animals possess so delicate a sense of touch as Chiroptera. In ordinary bats tactile organs exist, not only in the bristles on the sides of the muzzle, but in the sensitive structures forming the wing-membranes and ears, while in many species leaf-like expansions surrounding the nasal apertures or extending backwards behind them are added. These nose-leaves are made up partly of the extended and thickened integument of the nostrils, and partly of the glandular eminences occupying the sides of the muzzle, in which other bats the sensitive bristles are implanted.

In no mammals are the ears so developed or so variable in form; in most insectivorous species they are longer than the head, while in the long-eared bat their length nearly equals that of the head and body. The form is characteristic in each of the families; in most the "earlet," or tragus, is large, in some cases extending nearly to the outer margin of the conch; its office appears to be to intensify and prolong the waves of sound by producing undulations in them. In the Rhinolophidae, the only family with insectivorous bats wanting the tragus, the auditory bullae reach their greatest size, and the nasal appendages their highest development. In frugivorous bats the ear is simple and but slightly variable. In all bats the ears are extremely mobile, each independently at will.

The oesophagus is narrow, especially in blood-sucking vampires. The stomach presents two types of structure, corresponding respectively to the two divisions of the order, Megachiroptera and Microchiroptera; in the former the pyloric extremity is, with one exception, elongated and folded upon itself, in the latter simple; an exceptional type is met with in the blood-suckers, where the cardiac extremity is elongated, forming a long appendage. The intestine is comparatively short, varying from one and a half to four times the length of the head and body; longest in the frugivorous, shortest in the insectivorous species.

In Rhinopoma and Megaderma a small caecum has been found.

The liver is characterized by the great size of the left lateral lobe, which occasionally equals half that of the whole organ; the right and left lateral fissures are usually very deep; in Megachiroptera the splenial lobes, with one exception, ill-defined or absent, and the caudate is generally large; but in Microchiroptera the former lobe is large, while the caudate is small. The gall-bladder is generally well developed.

In most species the hyoids are simple, consisting of a chain of slender, long, cylindrical bones connecting the basi-hyoid with the skull, while the pharynx is short, and the larynx shallow with feebly developed vocal cords, and guarded by a short pointed epiglottis. In the African epauletted bats, Eptonomorphus, the pharynx is long and capacious, the aperture of the larynx far removed from the fauces, and, opposite to it, opens a canal, leading from the nasal chambers, and extending along the back of the pharynx; the larvyngeal cavity is spacious and its walls are ossified; the hyoids are unconnected, except by muscle with the skull; while the cerato-hyals and ep-hyals are cartilaginous and expanded, entering into the formation of the walls of the pharynx, and (in males of some species) supporting the orifices of a pair of air-sacs communicating with the pharynx (fig. 2).

The extent and shape of the wings generally depend on the form of the bones of the fore-limbs, and on the presence or absence of the tail. The wings consist of an "antebrachial membrane," which extends from the point of the shoulder along the humerus and more or less of the fore-arm to the base of the thumb, the metacarpal bone of which is partially or wholly included in it; the "wing-membrane" spread out between the elongated fingers, and extending along the sides of the body to the posterior extremities, generally reaching to the feet; and the "interfemoral membrane," the most variable of all, which is supported between the extremity of the body, the legs and the calcar (fig. 1). The antebrachial and wing membranes are most developed in species fitted only for aerial locomotion which when at rest hang with the body enveloped in the wings;
but in the Emballonuridae, and also in the Molossinae, which are the best fitted for terrestrial progression, the antibrachial membrane is reduced to a small size, and not developed along the fore-arm, leaving the thumb quite free, while the wing-membrane is narrow and folded in repose under the fore-arm. The relative development of the interfemoral membrane has been referred to in connection with the caudal vertebrae. Its small size in the frugivorous and blood-sucking species, which do not require it, is easily understood. Scent-glands and pouches opening on the surface of the skin are developed in many species, but in most cases more so in males than in females (fig. 3). As a rule, bats produce only a single offspring at a birth, which for some time is carried about by the female parent clinging to the fur of her breast; but certain North American bats commonly give birth to three or four young ones at a time, which are carried about in the same manner.

Bats are divisible into two suborders, Megachiroptera and Microchiroptera.

**Megachiroptera.**

The first of these comprises the fruit-eating species, which are generally of large size, with the crowns of the cheek-teeth smooth and marked with a longitudinal groove. The bony palate is continued behind the last molar, narrowing slowly backwards; there are three phalanges in the index finger, the third phalange being terminated generally by a claw; the sides of the ear form a ring at the base; the tail, when present, is inferior to (not contained in) the interfemoral membrane; the pyloric extremity of the stomach is generally much elongated; and the spigellional lobe of the liver is ill-defined or absent, while the caudate is well developed. This group is limited to the tropical and sub-tropical parts of the Eastern Hemisphere.

All the members of this suborder are included in the single family Pteropodidae, the first representatives of which are the African epauletted bats, forming the genus Eumops. In this the dental formula is i. 3 (or 4), c. 1, p. 3, m. 3. Tail short or absent, when present free from the interfemoral membrane; second finger with a claw; premaxillae united in front. The species are strictly limited to Africa south of the Sahara, and are distinguished by the large and long head, expandable and often folded lips, and the white tufts of hair on the margins of the ears. The males are provided with glandular pouches, situated in the skin of the side of the neck near the point of the shoulder, which are rudimentary or absent in females. In the males they are lined with glandular membrane, from which long coarse yellowish hairs project to form conspicuous epaulet-like tufts on the shoulders. The males often have a pair of air-sacs extending outwards on each side from the pharynx beneath the integument of the neck, in the position shown in fig. 2. These bats appear to live principally on figs, the juicy contents of which their voluminous lips and capacious mouths enable them to swallow without loss. The huge and ugly West African hammer-headed bat, Hypsignathus monstrosus, represents an allied genus distinguished by the absence of shoulder-pouches, and the presence of leaf-like expansions of skin on the front of the muzzle, and of distinct cusps on the outer sides of the cheek-teeth. The great majority of the bats of this group, commonly known as "flying-foxes," are included in the typical genus Pteropus, of which the dental formula is i. 3, c. 1, p. 3, m. 3. All are of large size, and the absence of a tail, the long pointed muzzle, and the woolly fur covering the neck render their recognition easy. One of the species, P. edulis, inhabiting Java, measures 5 ft. across the fully extended wings, and is the largest member of the order.

The range of the genus extends from Madagascar through the Seychelles to India, Ceylon, Burma, the Malay Archipelago, Japan, New Guinea, the Philippine Islands, and Australia. A large group of two species inhabit the Comoro Islands, scarcely 200 m. from the mainland, not one is found in Africa; while the common Indian species is closely allied to the Madagascar flying-fox. The Malay Archipelago and the south-west coast of Asia, which are the countries of departure of these bats, have some places occur in countless multitudes. The colonies exhibit a strong musky odour, and when the occupants utter a loud incessant chatter, Wallace's fruit-bat of Celebes and Macassar has been made the type of a separate genus, Sphyilocynus wallacei. In Rousettus (or Rousetta) the dentition is as in Pteropus, but the tail is short, and the fur of the nape of the neck not different from that of the back: its distribution agrees with that of Pteropus, except that it includes Africa and does not reach farther east than New Ireland. R. acutus inhabits the various islands of the Great Pyramid and other deserted buildings in Egypt, and is probably the species figured in Egyptian frescoes. Bonetta, with two species, from Celebes, differs in having only two upper incisors. Harpyionycteris and Scutonycteris, respectively from the Philippines and West Africa, are represented by a single species each; but Cynopterus, which is mainly confined to the Indo-Malay countries, there are some half-dozen different kinds. The dentition is i. 2 or 3, c. 1, p. 3, m. 3. The muzzle is shorter than in Rousettus, with the upper lip grooved in front as in Pteropus, while the tail and fur resemble those of the former genus. These bats are extremely voracious, a species of the Indian C. marginata having eaten a banana twice its own weight in three and the tongue exceedingly long, attenuated in the anterior third, and armed with long recurved papillae near the tip. The single representative of the first genus, Niopterus macdonaldi, inhabiting Fiji, New Guinea and the New Hebrides, is distinguished from other bats of this family by the length of its tail, which is nearly as long as the body.
as the forearm. The dentition is i. 3, c. 1, p. 3, m. 3, while the index finger has no claw, and the wings arse from the spine. Eonycteris, with the dentition i. 3, c. 1, p. 3, m. 3, is also represented by a single species, E. spelaea, from the Neander, Burma, and the Malay Peninsula and islands, which has a somewhat flattened lower jaw, but the absence of a claw in the index finger and the presence of the characteristic tongue and teeth at once distinguish it. Carpyonctes (Macroglossus) and Melonctes, the former with several and the latter with the index finger of a single species, and the latter with a single species, have large and Papuan genera, the index finger in both having a claw, but the number of the teeth being the same as in Eonycteris. C. minimus is the smallest known species of the suborder, much smaller than the serotine bat of Europe in the size of some smaller species, and has no transverse membrane. It is nearly as common in certain parts of Burma as Eonycteris marginatus, and extends eastwards through the Malay Archipelago as far as New Ireland, where it is associated with Meloglossus and Melanonycteris. In India, the only species is found in the island of Java, where it has a very large size, and is not found in the surrounding islands. The inner margin of the species, with the large size of the Horseshoe bat, which is not lancedelate behind (fig. 6), and is unprovided with a central process covering the nostrils; the largest species, H. chrysops, appears to be the most northerly, having been taken at Amur in Russia, and in the Himalaya at elevations of 5000 ft.

Many are provided with a frontal sac behind the nose-leaf, rudimentary in females (see fig. 7), which can be everted at pleasure; the sides of this sac secrete a waxy substance, and the extremity supports a tuft of straight hairs. Rhinonycteris, represented by R. aurantias, R. australis, and R. perotis from Persia and other species from Africa and Madagascar, are closely allied; the species is characterized by the remarkable form of its nasal appendages and ears, and the presence of a bony raised on the upper extremity of the second phalange of the fourth finger. C. fruhri, a rare species, found in Java and Siam, is distinguished by the peculiar form of its nose-leaf and the length of the vocal sac. It is larger, as well as by the shortness of the calcar and intermembrane. Closeotis is represented by a single East African species, and Anotus by one from the Solomon Islands characterized by the nose-leaf covering the whole front of the body.

The next family, Nycteridae, is also Old World, is a small one, nearly allied to the last, in which it is included by Prof. Max Weber as a subfamily under the name of Myodermatinae. It differs by the presence of a small tragus in the posterior edge of the nose-leaf, and by the presence of a bony intermembrane, which is much expanded vertically and laterally. In females a pair of hair-like processes extend from the base of the nose-leaf, and the long tail extends to the margin of the intermembrane. The middle finger has two phalanges, but the inner is rudimentary. The forefinger is rudimentary. The Rhinolophidae are the most organized of insectivorous bats, in which the osseous and cutaneous systems are the fullest developed. The palm of the hand is pitted with numerous small papules; and the long tail extends to the margin of the intermembrane. The middle finger has two phalanges, but the inner is rudimentary.

The Rhinolophidae are the most organized of insectivorous bats, in which the osseous and cutaneous systems are the fullest developed. The palm of the hand is pitted with numerous small papules; and the long tail extends to the margin of the intermembrane. The middle finger has two phalanges, but the inner is rudimentary.
to Africa and the Malay Peninsula and Islands, has ossified pre-maxillae and upper incisors (t. §. p. §), and a long tail, but lacks a nose-leaf. As in Megaderma, the frontal bones are deeply hollowed and expanded laterally, the muzzle presents a similar cylindrical form, and the lower jaw also projects; but, instead of a nose-leaf, the face is marked by a deep longitudinal sharp-edged groove ex-

with white streaks. A few species, probably all those with the tail and intermembranal membrane well developed, feed principally on insects, while the greater number of the species of the groups Vampyreae and Glossophageae appear to live on a mixed diet of insects and fruits, and the Desmodontidae, of which two species are known, are true blood-suckers, and have their teeth and intestinal tract specially modified in accordance with their habits. The group is practically limited to the tropical and subtropical parts of Central and South America, although one species of Oedipus reaches Cali-

Chiroptera

form. In the first subfamily, Mormopsinae (Lobostominae), the nostrils open by simple apertures at the extremity of the muzzle in front, not margined by a distinct nose-leaf; while, in compensation, the chin is furnished with expanded leaf-like appendages. The tail is usually more or less developed, and it includes the intermembranal membrane. In this group may be mentioned the two species of tropical American hare-lipped bats, forming the genus Nocto, which presents characters common to this and the following family, to which latter it is often referred. The typical N. leporinus is a bat of cutaneous aspect, with strangely folded lips, erect skin-processes on the chin, and enormous feet and claws. The two middle incisors are close together, and so large as to conceal the small outer ones, while in the lower jaw there are but two small incisors; the premolar is separated. These bats live near the coast, and feed on small crabs and fishes.

Most of the remaining members of the family are included in the subfamily Phyllostominae, characterized by the presence of a distinct nose-leaf and the warty chin. The clitoris is imperfect, whereas it is perforated in the Mormopsinae. The incisors are generally 4 (occasionally 2), and the molars well developed. The subfamily is divided into a number of groups or sections. The first of these, the Vampireae, is characterized as follows: The eyes are long in front, the distance between the eyes generally less than (rarely equal to) that from the eye to the extremity of the muzzle; nose-leaf horse-shaped in front, lanulate behind; intermembranal membrane well developed; tail generally distinct, rarely absent; inner margin of the lips not fringed; t. §. p. §. or 4 molars with W-shaped cusps, usually well developed. Nearly all the Vampyrae appear to be insectivorous, so that the teeth are generally well developed in that respect; but in a few, if not all, probably supplement their insect-diet with fruit. Vam perus spectrum (the largest bat in the New World) is said to be wholly frugivorous, and Otopterus waterhousei appears to prey occasionally on eggs. The general form of the incisors according to Blainville is furnished with long, narrow, finely serrated incisors; and the anterior incisors of the upper jaw are barbed. Vampyra nigrirostris is characterized by L. aurita, characterized by an extraordinary long nose-leaf, and peculiarly large ears and tragus. In the second subsection are included Vampyra, Chiroptor, Tonatol (Lophostoma) Micronycteris, Chalinolobus, Trachops, Phyllobothria, Phyllodina, and Anoura (Tylostoma), Minnow, Hemiderma (Cardio) and Rhynohypha; all, with the exception of the last, distinguished chiefly by the form of the skull and the presence or absence of the second lower premolar. Phyllostominae includes the families Phyllodinidae and many of the smaller families of Vampyraeae, as well known species in South America: P. elongatius, the厉, small, large ears and tragus. The second subsection includes Vampyra, Chiroptor, Tonatol (Lophostoma) Micronycteris, Chalinolobus, Trachops, Phyllobothria, Phyllodina, and Anoura (Tylostoma), Minnow, Hemiderma (Cardio) and Rhynohypha; all, with the exception of the last, distinguished chiefly by the form of the skull and the presence or absence of the second lower premolar. Phyllostominae includes the families Phyllodinidae and many of the smaller families of Vampyraeae, as well known species in South America: P. elongatius, the...
breviceps, both in form and dentition. Its long brush-tipped tongue (which it possesses in common with other species of the group) is used to lick out the pulpy contents of fruits having hard rinds. The food of the species of this group appears to consist of both fruit and insects, and the long tongue may be utilized for both, as well as for digging out insects from the crevices of flowers. Other genera are Lophonycteris, Rhinolophus, and Nycticebus, each with a single species (in 1904).

The third subfamily, Sionycteridae, presents the following characteristics: muzzle very short and generally broad in front, the distance between the eyes nearly always exceeding (rarely equaling) the distance from the eye to the extremity of the upper incisors, separated by gaps from the canines, and from one another in the middle line.

The distinctive feature of these bats is the free tail-tip, which pierces the intermembranous membrane to appear on its upper surface, as a sort of fin, the inner side of which is represented by the peculiar form of the muzzle, which is obliquely truncated, the nostrils projecting more or less in front beyond the lower lip, by the first phalange of the middle finger being folded in position on the surface of the front bone, and by the presence of only one phalange in the index finger, and the short tail. The dental formula is generally i. 5 (sometimes 6 or 7), c. 1, p. 3, m. 2. (This subfamily may be further subdivided into two genera, of which the first, Emballonura, is characterized by the slender tail perforating the intermembranous membrane, so as to appear on its upper surface, the legs long with a seta; the incisors weak; and the pre-molars 3. The typical genus Emballonura presents the following features: i. 5, premolars 0, and 2, parts produced beyond the lower lip, forehead of the genus contains several species, Emballonura rafayana, inhabiting islands from Madagascar to Brazil.)

The intermembranous membrane, which is divided into eleven genera, mostly distinguished by the form of the skull and teeth. Arthus includes the frugivorous A. perspicillatus. Sionycteridae, with the upper incisors occupying the space between the teeth, with the last, from which it is scarcely distinguishable externally except by its longer size, differs in the animal of the palate. Stumira, while agreeing with these in the form of the nose-leaf, and tail, differs from all the species of the family in its longitudinally grooved molars, which resemble those in Pieridae. These genera are more closely related to each other than any other genera, and the presence of tufts of long, differently colored hairs on the body serves to distinguish these from the species. Stumira, Sionycteris, and other genera of this group by the absence of a distinct nose-leaf. Some naturalists make the genus下的 type of a distinct subfamily, Centurio. Up to 1904 the genera, exclusive of Centurio, included in the Sionycteridae were Arthurs (in 2 subgenera, 3 species), Vampyrodes (also with subgenera), Metopophora, Cherodorina, Sionycteris (with 3 subgenera), Ectophora, Ametrida (with 2 subgenera), Pygoderma, Stumira and Brachyotis.

Desmodus, represented only by the blood-sucking bats, and distinguished by having i. 5, of which the upper pair are cutaneous, the rudimentary molars, the very short intermembranous membrane, and the bloom of the habit. They are further characterized as follows: Muzzle short and conical; nose-leaf distinct; p. 8, m. 4, i. 5; upper incisors occupying the space between the canines; premolars narrow, with sharp-edged longitudinal crowns; molars rudimentary or absent; stomach single, with branches, and upper and lower tails. There are 2 genera, Desmodus, without calcify or molars, and Desmodus, with a short calcify and a single rudimentary tooth, in which the molars, restricted to Central and South America. Desmodus rotus, the common species, is a little larger than the noctule bat, and abundant in certain parts of South America, where it is troublesome owing to its attacks upon domestic animals, sucking its blood, and in colonies, leaving them weakened from repeated bleedings. (See Vampyrodes.)

The fourth family of bats, unlike any of the three previous ones, has a cosmopolitan distribution. These free-tailed bats, as they are commonly called, are found in Asia, Australia, and America. They are found in large numbers, often in the hundreds or thousands, in colonies, in the tops of trees, and in caves. The ears are large, with a small tragus. The middle finger has two phalanges, and the index generally a single one. The fibula is incomplete. The tail is generally short, and partly free from the proememoral membrane. There is generally only one pair of

![Figure 14](image3.png)

**Figure 14** - Ear of Desmodus rotus, the Navigator Islands. Coleura, with 1, 3, the extremity of the muzzle broad, and the forehead concave, has two species, from East Africa and the Seychelles. Rhyynchonycteris is distinguished by Crowther's C. c. having the fur of the body and of small tufts on the antibrachial membrane counterfeiting the weathered surfaces of rocks and bark. As evening approaches it appears on the wing, flying close to the water. Saccopteryx has 1, 5, and the antibrachial membrane with a pouch opening on the surface. This subfamily has several species from Central and South America. This sac is developed only in the male and in the female is rudimentary. In adult males a valvular longitudinal opening occupies the upper surface of the membrane leading into a small pocket, the interior of which is a gland which secretes an unctuous reddish substance with a strong amniacal odour. Allied genera are the tropical American Peropygue and the Brazilian Carinura. The various species of tomb-bats (Taphosus) resemble the tropical and tropical bats of all the eastern hemisphere except Polynesia, and are distinguished by the cartilaginous premaxillaries, the deciduous pair of upper incisors, and the presence of only two pairs of lower incisors. Most of the species have a glandular sac (fig. 15) between the edges of the lower jaw, more developed in males than in females, in some species absent in the

![Figure 15](image4.png)

**Figure 15** - Heads of Tomb-Bat (Taphosus longimanus), showing relative development of throat-sacs in male and female. From Dobson.

latter. An open throat-sac is wanting in T. malapogon, but about its position are the openings of small pores, the secretion from which probably causes the hairs to grow long, forming the black beard found in many males. The three tropical American white bats, Desmodus, with 1, 5, c. 1, p. 3, m. 3, resemble Taphosus in the form of the head and ears, but, besides other characters, differ from other bats in possessing a pouch, opening off the centre of the throat of the mouse-tailed bats; the extremity of the tail enters this, and perforates its base.

The second subfamily of the Emballonuridae, Rhinolophomatinae, is represented only by the genus Rhinolophus, with several species ranging from Egypt through Arabia to India, Burma and Sumatra. The premaxillaries (fig. 16) are subquadrangular; the index finger has two phalanges; the tail is very long and mouse-like; and the dental formula i. 5, c. 1, p. 3, m. 3, Dr. G. E. Dobson has remarked that these mouse-tailed bats might be elevated to the rank of a family, for they are difficult to determine their affinities, a kind of cross relation to them of the Nectaridae on the one hand and to the Emballonuridae on the other. These bats, distinguished from all other Microchiroptera by the presence of two phalanges in the index finger.
and the long and slender tail projecting far beyond the narrow inter-

temoral membrane, inhabit the subterranean tombs in Egypt and
deserted buildings generally from north-east Africa to Burma and
Sumatra.

The last group, according to the system adopted by Prof. Max
Weber, is that of the Vespertilionidae, which includes such typical
bats as the pipistrelle, the noctule, and the long-eared species.
By Mr. G. S. Miller the first section of the family, the extinct
sweat family, or Molossina, is included by Dr G. E. Dobson in the
Emballonuridae, from the typical forms of which its members differ
widely in tail-structure. In this extended sense the family, which
has a cosmopolitan distribution, may be divided into two genera:
The nose-leaf of the former, or Xyonic, is included in the
Molossidae. In the last section, Natalidae, which is exclusively tropical
American, the other upper incisors are separated from one another
by the canines; palatine processes of the premaxillae are at least partially developed; and the dental formula is i. 4, c. 1, p. 2 or 3,
m. 3. In general appearance these bats recall

**Typical Bats.**

The first two genera, *Vespertilio* and *Myotis*, each have a single
species, the latter being distinguished from the former by the
wide separation of the nostrils and the backward prolongation of the
plate. In both the crown of the head is elevated, the thumb and
first phalanx of the middle finger are very short, and the premaxillae
are large. These are characteristic of the group *Natalus* and *Chiroptera* (fig. 17), in which the premaxillae are 1:
in
premaxillae widely separated; the ears medium or large; the dental
formula is i. 4, c. 1, p. 2 or 3, m. 3; and the fur is very fine and
imperfect. All the members of this large cosmopolitan group are
closely allied, and differ chiefly by external characters.

The last group of bats is divided into many genera; the most
typical, and the last section, or Molossina, is included by Dr G. E. Dobson in the
Emballonuridae, from the typical forms of which its members differ
widely in tail-structure. In this extended sense the family, which
has a cosmopolitan distribution, may be divided into two genera:
The nose-leaf of the former, or Xyonic, is included in the
Molossidae. In the last section, Natalidae, which is exclusively tropical
American, the other upper incisors are separated from one another
by the canines; palatine processes of the premaxillae are at least partially developed; and the dental formula is i. 4, c. 1, p. 2 or 3,
m. 3. In general appearance these bats recall

CHIROPTERA

of three or four offspring at a birth. Rhogeessa and Tomopous are allied tropical American types. Manus, with the subgenus Harpio-
ccephalus, has i. ½, p. ½, and includes several small bats distinguished by the prominent tube-like nostrils and hairy intermembrane, Manus, from Java, the Malay and Borneo islands, is a well
known species, and the closely allied M. hilgendorfi is from Japan.
The remaining species are from the Himalaya, Tibet and Ceylon; and apparently restricted to the hill-tracts of the countries in which they are found. Next to Vespertilia is the genus Myotis (divisible into
several subgenera), with i. ½, p. ½, includes the largest number of
species, and has rather a wider geographical distribution in both
hemispheres, some species being recorded from the Navigating Islands.
The species may be recognized by the peculiar character of the pairs of
upper incisors on each side, the cusps of which are of different shapes;
the upper incisors of one species are large, small, and numerous; those
of another, by the number of premolars, of which the second upper is
always small, and by the oval elongated ear and narrow tragus.
The British M. bechsteinii and M. nattereri are examples of this group.
Content, when they differ, are distinguished by the parallel upper incisors and the large second upper premolar. There are
numerous African and Indo-Malayan species, of which C. picta,
from India and Indo-Malay, is characterized by its brilliant orange
fur, and membranes variegated with orange and black. The genus
includes delicately formed insectivorous, tropical, forest-haunting
bats, whose colouring approaches them to the ripe bananas among
which they often pass the daytime.

Another sub-group, Miniopterus, is represented solely by the genus
Miniopterus, with i. ½, p. ½. The incisors are separated from one
another in front and from the canines; the first phalange of the
middle finger is very short, the crown of the head elevated, and
the tail is well-developed. The type of the group the premaxillae are
in contact on the lower side, and the ears are large, with the
tragus small; the dental formula is i. ½, c. 1, p. ½, m. ½, and
the fibula is strongly developed. In their blunt muzzles and
many other features these bats undoubtedly resemble the Emballonu-
rus, and are often mistaken for them, differing by the presence of
the thick tail far beyond the margin of the intermembrane.
They are further characterized by their broad and stout feet, in
which case the first, and in most cases also the fifth, toe is
thicker than the rest, and furnished with long bent hairs; and by
the presence of callosities at the base of the thumbs, and a single
pair of large upper incisors occupying the centre of the space between
the canines. The feet are free from the wing-membrane, which
folds up under the fore-arm and legs; the intermembrane is
retractile, being movable backwards and forwards along the tail;
this power of varying its superficial extent confers on these bats
great dexterity in changing the direction of flight. All are able to
walk or crawl well, and spend much of their time on trees. The
genus Chromous, with i. ½, c. ½, p. ½, m. ½, the first hind-toe much
larger than the others, and the widely enameled ears, is represented by C. torquata, a large bat of peculiar aspect, inhabiting the
large islands of the Indian Ocean. The species is characterized
by a collar of thinly spread hairs half surrounding the neck, and
is remarkable for its enormous throat-sac and nurse-pouches.
The former consists of a semicircular fold of skin forming a pouch
round the neck and breast, concealing the surfaces of subcutaneous
pectoral muscles; and each discharge an oily fluid of offensive smell.
The nursing-pouch is formed on each side by an extension of a fold of
skin from the side of the body to the inferior surfaces of the humerus
and femur. In the anterior part of this pouch the skin is placed.
The typical genus Myotis (fig. 21) includes the mastiff-bats,
characterized by the dental formula i. ½, c. ½, p. ½, m. ½; and by
the

tuberocladius), enlarged. (From Dobson.)

with one species; while Nyctinomops includes a number of tropical
American species more nearly related to the next genus, in which
some of them (fig. 22) were formerly included. The widely spread
Nyctinomops, with i. ½, p. ½, and the upper incisors separate
one of the largest species, along the tropical and
subtropical parts of both hemispheres. The lips of the bats of this
genus are even more expansible than in Molossus, in many of the
species (fig. 22) showing vertical wrinkles. N. tomentosus (or cestus),
one of the largest species, along the tropical and
subtropical parts of both hemispheres. The lips of the bats of this

Palaeontology tells us nothing with regard to the origin of the
Chiroptera, all the known fossil species, some of which date
back to the Oligocene, being more or less closely allied to existing
types, and therefore of comparatively little interest. The origin
of the order from primitive insectivorous mammals must have
taken place at least as early as the Lower Eocene. It is, however,
noteworthy that several of the earlier extinct species appear to
be related to the Mystacopsidae, which is the most generalized
family of the order. Remains of Perotidaeia belonging to
existing genera occur in the caves of tropical countries in the
eastern hemisphere; and the skeleton of an extinct generic type,
Archaeopteryx, has been obtained from the Miocene
lignite of Italy, which indicates a form to a certain extent
transitional in character between the two orders. Some of the
insectivorous bats, the tail, when, among modern fruit-bats is rudimentary, with only three or four vertebrae, in
the fossil has eight complete vertebrae; while the teeth of the

extinct form are distinctly cepsed. Whether, however, the tail is longer than in the existing Notoceros of Fiji and New Guinea, or whether the molars are more distinctly cepsed than is the case with the Solomon Island Pteropus (Pteropodidae), is not stated. Still, the fact that the Miocene fruit-bat does show certain signs of approximation to the insectivorous (and more generalized) section of the order is of interest. Of the Oligocene forms, Pseudorhinolophus of Europe is apparently a member of the Rhinolophidae; but the affinities of Alister and Vespertilius, which are likewise European, are more doubtful, although the latter may be related to Taphozous.

The North American Vesperillio (Vesperugo) anemophilus and the European V. aquensis and V. parisienis are, on the other hand, members of the Vespertilionidae, the last being apparently allied to the serotine (V. serotinus).

**CHITON—CHITON**

CHITON, a graceful Tibetan antelope (Pantholops Hodgsoni), of which the bucks are armed with long, slender and heavily-ridged horns of an altogether peculiar type, while the does are hornless. Possibly this handsome antelope may be the original of the mythical unicorn, a single buck when seen in profile looking exactly as if it had but one long straight horn. Although far from uncommon, chiru are very wary, and consequently difficult to approach. They are generally found in small parties, although occasionally in herds. They inhabit the desolate plateau of Tibet, at elevations of between 13,000 and 18,000 ft., and, like all Tibetan animals, have a firm thick coat, formed in this instance of close woolly hair of a grey fawn-colour. The most peculiar feature about the chiru is, however, its swollen, puffy nose, which is probably connected with breathing a highly rarefied atmosphere. A second antelope inhabiting the same country as the chiru is the soa (Gazella picticaudata), a member of the gazelle group characterized by a narrow body, short legs, and the presence of a large band of black and white markings on the flanks, sides, and legs. The latter is the more easily distinguished from all the others by one or two other central Asian species. The chiru, which belongs to the typical or antilope section of antelopes, is probably allied to the saiga.

**CHIRURGEN**, one whose profession it is to cure disease by operating with the hand. The word in its original form is now obsolete. It derives from the Mid. Eng. cirurgien or suruergien, through the Fr. from the Gr. χύρουργος, one who operates with the hand (from χυρόν, hand, ἐρυν, work); from the early form is derived the modern word "surgeon." "Chirurgeon" is a 16th century reversion to the Greek original. (See Surgery.)

**CHISEL** (from the O. Fr. isel, modern is, Late Lat. iselium, a cutting tool, from isere, to cut), a sharp-edged tool for cutting metal, wood or stone. There are numerous varieties of chisels used in different trades; the carpenter's chisel is wooden-handled with a straight edge, transverse to the axis and bevelled on one side; stone masons' chisels are bevelled on both sides, and other Schmiedezeug, a concave-convex edge. A chisel with a semicircular blade is called a "gouge." The tool is worked either by hand-pressure or by blows from a hammer or mallet. The "cold chisel" has a steel edge, highly tempered to cut unheated metal. (See Tool.)

**CHISLEHURST**, an urban district in the Sevenoaks parliamentary division of Kent, England, 114 m. S.E. of London, by the South-Eastern & Chatham railway. Pop. (1901) 7429. It is situated 300 ft. above sea-level, on a common of furze and heather in the midst of picturesque country. The church of St Nicholas (Perpendicular with Early English portions, but much restored) has a tomb of the Walsingham family, who had a lease of the manor of Elizabeth; Sir Francis Walsingham, the statesman, being born here in 1556. Another statesman of the same age, Sir Nicholas Bacon, was born here in 1566. Near the church is an ancient cockpit. The mortuary chapel attached to the Roman Catholic church of St Mary was built to receive the body of Napoleon III., who died at Chislehurst in 1873; and that of his son was brought hither in 1879. Both were afterwards removed to the memorial chapel at Farnborough in Hampshire. Camden Place was built by William Camden, the antiquary, in 1609, and in 1765 gave the title of Baron Camden to Lord Chancellor Pratt. The house was the residence not only of Napoleon III., but of the empress Eugénie and of the prince imperial, who is commemorated by a monumental cross on Chislehurst Common. The house and grounds are now occupied by a golf club. There are many villa residences in the neighbourhood of Chislehurst.

**CHISWICK**, an urban district in the Ealing parliamentary division of Middlesex, England, suburban to London, on the Thames, 7 f. W. by S. of St Paul's cathedral. Pop. (1901) 29,850. The locality is largely residential, but there are breweries, and the marine engineering works of Messrs Thornycroft on the river. Chiswick House, a seat of the duke of Devonshire, is surrounded by beautiful grounds; here died Fox (1766) and Campbell (1808). The Sir Allen Lithgow placed there longed till 1909 to the Royal Horticultural Society. The church of St Nicholas has ancient portions, and in the churchyard is the tomb of William Hogarth the painter, with commemorative lines by David Garrick. Hogarth's house is close at hand. Chiswick Hall, no longer extant, was formerly a country seat for the masters and sanatorium for the scholars of Westminster school. Here in 1811 the Chiswick Press was founded by Charles Whittingham the elder, an eminent printer (d. 1840).

**CHITA**, a town of east Siberia, capital of Transbaikalia, on the Siberian railway, 500 m. E. of Irkutsk, on the Chita river, half a mile above its confluence with the Ingoda. Pop. (1883) 12,600; (1897) 11,480. The Imperial Russian Geographical Society has a museum here. Several of the palace revolutionaries, known as Decembrists, were banished to this place from St Petersburg in consequence of the conspiracy of December 1825. The inhabitants support themselves by agriculture and by trade in furs, cattle, hides and tallow bought from the Buriats, and in manufactured goods and produce from the Germans and the Tartars.

**CHITALDRUG**, a district and town in the native state of Mysore, India. The district has an area of 4022 sq. m. and a population (1901) of 4087,95. It is distinguished by its low rainfall and arid soil. It lies within the valley of the Vedavati or Hagar river, mostly dry in the hot season. Several parallel chains of hills, reaching an extreme height of 3800 ft., cross the district; otherwise it is a plain. The chief crops are cotton and flax; the chief manufactures are blankets and cotton cloth. The west of the district is served by the Southern Mahratta railway. The largest town in the district is Davangere (pop. 10,402). The town of Chitaldrug, which is the district headquarters (pop. 1901, 5792), was formerly a military cantonment, but this was abandoned on account of its unhealthiness. It has massive fortifications erected under Hyder Ali and Tippoo Sahib towards the close of the 18th century; and near it on the west are remains of a city of the 2nd century A.D.

**CHITON**, the name given to fairly common littoral animals of rather small size which belong to the phylum Mollusca, and, in the possession of a radula in the buccal cavity, resemble more especially the Gastropoda. Their most important characteristic in comparison with the latter is that they are, both in external and internal structure, bilaterally symmetrical. The dorsal integument or mantle bears, not a simple shell, but eight calcareous plates in longitudinal series articulating with each other. The ventral surface forms a flat creeping "foot," and between mantle and foot is a pallial groove in which there is on each side a series of gills. Originally the Chitons were placed with the limpets, Patella, in Cuvier's Cylindrichnia, an order of the Gastropoda. In 1876 H. von Jhering demonstrated the affinities...
of Neomenia and Chaetoderma, veriform animals destitute of shell, with the Chitons, and placed them all in a division of worms which he named Amphipneura. The discovery by A. A. W. Hubrecht in 1881 of a typical molluscan radula and odontophore in a new genus Proneomenia, allied to Neomenia, showed that the whole group belonged to the Mollusca. E. Ray Lankester (Ency. Brit., 6th ed., 1883) placed them under the name Isopleura as a subclass of Gastropoda. Paul Pelseneer (1906) raised the group to the rank of a class of Mollusca, under von Jhering's name Amphipneura.

The Amphipneura are divided into two orders: (1) the Polyplacophora, or Chitons; (2) the Aplacophora, or forms without shells, Neomenia, Chaetoderma and their allies.

Order I.—Polyplacophora

Each of the eight valves of the shell is made up of two distinct calcareous layers: (a) an outer or upper called the tegument, which is visible externally; (b) a deeper layer called articulation which is porcellaneous, quite compact, and entirely covered by the tegument. In the lower forms the two layers are coextensive and have smooth edges, but in the higher forms are termed insertion plates; they are usually slit or notched to form teeth, the edges of which may be smooth and sharp, or may be crenulated. The anterior margin of each valve except the first is provided with two projections called sutural laminae which underlie the posterior margin of the preceding valve.

The tegument is formed by the fold of mantle covering the edge of the articulation, and extends over the latter from the sides. It is the first part of the shell formed in development. The tegument is much reduced in Acanthochiton, and absent in the adult Cryptochiton.

The tegument is pierced by numerous vertical ramified canals which contain epithelial papillae of the epidermis. These papillae form pallial sense-organs, containing nerve-end bulbs, covered by a dome of cuticle, and innervated from the pallial nerves. They are termed according to their size, microaesthethes and megaaesthethes. In the common species of Chiton and many others of the family Chitonidae the megaaesthethes are developed into definite eyes, the most complicated of which have retina, pigment within the eye, cornea and crystalline lens (intra-pigmental eyes) (fig. 2). The eyes are arranged in rows running diagonally from the median anterior beak of each valve to its lateral borders.

There may be only one such row on either side, or many rows. In some species the total number present amounts to thousands.

Branchiae.—The series of gills may extend the whole length of the body in the pallial groove, or may be confined to the posterior end. Each gill has the structure of a typical molluscan ctenidium, consisting of an axis bearing an anterior and posterior row of filaments or lamellae. The gills are thus metamERICALLY repeated; there may be from four to eighty pairs, but there is
often a numerical asymmetry on the two sides. The largest pair of branchiae is placed immediately behind the renal openings and corresponds to the single pair of other molluscs, the organs being repeated anteriorly only (Metcamicrobranches) or anteriorly and posteriorly (Mesomacrobranches).

Digestive System.—The digestive tube in the Polyplacophorae, which are herbivorous, is longer than the body, and thrown into a few coils, the anus being median and posterior. The mouth leads into the buccal cavity, on the ventral side of which opens the radular caecum. Each transverse row of teeth of the radula contains 17 teeth, one of which is median, while the second and the fifth on each side are enlarged. Two pairs of glands open into the buccal cavity, and at the junction of pharynx and oesophagus is another pair called the sugar glands. The stomach is surrounded by the liver or digestive gland, consisting of two lobes which are symmetrical in the young animals, but in the adult the right lobe is anterior and smaller.

Excretory System.—The heart is enclosed in the pericardium, and consists of a median elongated ventricle and a pair of lateral auricles, so that the structure somewhat resembles that in the Lamellibranchia. The openings of the auricles into the ventricle vary in different forms. In many of the lower forms (Lepidopleuridae, Mopalaia, Ischnochitonidae) the opening on each side is single and anterior. In the true Clitoniidae there are generally two apertures on each side, and in two species three or four, another instance of the tendency to metameric repetition in the adult. The auricles are connected with one another posteriorly behind the ventricle. The ventricle leads into a single anterior median aorta. As in other molluscs, the arteries do not extend far, but lead into inter-vascular blood-spaces. The venous blood is conducted from the tissues to a large sinus on either side above the pallial groove, and from this sinus passes to the gills by an afferent vessel in each gill on the internal or pedal margin of the axis. The oxygenated blood is carried from each gill by an efferent vessel to the external or pallial side of the axis to another longitudinal vessel which leads to the auricle on each side.

Nervous System.—There are no well-marked specialized ganglia in the central nervous system, nerve-cells being distributed uniformly along the cords. There are two pairs of longitudinal cords, a pedal pair situated ventrally and united beneath the intestine by numerous commissures, and a pallial pair situated laterally and continuous with one another above the rectum (fig. 7). The four cords are all connected anteriorly with the cerebral commissure which lies above the buccal mass anteriorly. From the points where the cords meet the cerebral commissure, arise on each an anterior labial commissure and a stomatogastric commissure. The latter bears two ganglion swellings, the buccal ganglia. The labial commissure gives off a subradular commissure which also bears two ganglia, the pairs being in close relation to a special sense-organ called the subradular organ, an epithelial projection with nerve-ends, lying in front of the radula and probably gustatory in function. One oesophagus or branchial olfactory organ is usually present on each side, on either side of the anus on the inner wall of the mantle, or on the base of the last gill. In Lepidopleuridae the oesophagus lies just behind the base of the last gill. The sense organs of the shell-valves have already been described.

Development.—The eggs may be laid separately invested by a chitinous envelope, or as in Ischnochiton magdaiensis they may form strings containing nearly 1000 eggs, or the ova may be retained in the buccal groove and undergo development there, as in Chiton pectin and Hemiarthra semiplana. One species Chiton violaceus is viviparous and its ova develop without a larval stage in the maternal ovicase. Segmentation is total and at first free, but if development is lifeless, the blastopore passing to the position of the future mouth. By the development of a ciliated ring just in front of the mouth the embryo becomes a trochosphere. In the centre of the praeoral lobe is a tuft of cilia. Just behind the ciliated ring is a pair of larval eyes which disappear in the adult; these correspond to the cephalic eyes of Lamellibranchs. An ectodermal invagination forms a large mucous gland on the foot, which is more or less atrophied in adult life. The gonads originate by proliferation of the anterior wall of the pericardium. The shell-
Valves arise as transverse thickening of the dorsal cuticle behind the ciliated ring, the tegument being the first part formed.

**Classification.**

**Suborder I. Eoplacophora, Pilsbry.**—Tegmentum coextensive with articulum centrum, or the latter projecting in smooth sulcal plates.

The extinct *Gryllochitonidae,* Pilsbry, with other Palaeozoic genera, narrow and elongated in form with terminal margins of end valves elevated, belong to this group.

**Suborder II. Mesoaplacophora, Pilsbry.**—Insertion plates well developed and slit.

*Fam. 2. Ischnochitonidae.*—All the valves with slits, and the inner layer well covered by the outer.

**Subfam. 1. Ischnochitoninae.**—No shell-eyes; sutural laminae separated; slits in the valves 1-7 do not correspond with the ribs of the truncum.

*Ischnochiton, Trachydermon, Chastepleuria, Stenoplax, Stenoradista.*

**Subfam. 2. Neomeniomorpha.**—Aplacophora with a distinct longitudinal ventral groove; bisexual with paired genital glands and no distinct duct. The whole of the skin except the ventral groove corresponds to the mantle of Chiton. The cuticle, in some species very thick, contains numerous spicules which are long, hollow and calcified; they are secreted by epithelial papillae. In some species there are also sensory papillae comparable to the aesthetes of Chiton. A small longitudinal projection in the ventral groove represents the

*Fig. 8.—Anterior part of the nervous system of Chiton cinereus.* A. Buccal ganglia (concerned with the odontophore), B. Cerebral nerve-mass, C. Pedal ganglion and commencement of pedal nerve-cord, D. Pedal nerve-cord, E. Sublingual ganglia not lettered.

*Subfam. 3. Callistoplaeidae.* No shell-eyes, slits in the valves 1-7 corresponding with the ribs of the tegument. *Callistochiton* (viviparous), *Nuttalliochiton.*

*Fam. 5. Cryptoplaeidae.* Vermiform, with thick girdle and small valves; insertion and sutural plates strongly drawn forward, sharp and smooth. *Cryptoplae, Chirex.*

*Suborder III. Teleoplacophora, Pilsbry.*—All the valves, or at least the seven anterior, with insertion plates cut into teeth by slits.

*Fam. 6. Chitonidae.* Characters of the suborder.

*Order 2.—Aplacophora,* von Linné.

*Chaetoderma* was first described by S. Lovén, in 1841, and was for a long time believed to be a Gephyrenean worm. *Neomenia,* mentioned first by M. Sars in 1868 under the name *Solena-*

*bus,* was afterwards included among the Opiatobranchs by J. Koren and D. C. Danielssen. C. Gegenbar placed the two genera in a division of Vermes which he called Solenogastres.

The chief points in which the Aplacophora differ from the Polyplacophora are: (1) they are worm-like in shape; (2) there is no distinct foot, and the mantle bears no shell-valves, but only numerous calcareous spicules; (3) the digestive tube is straight.

*Neomenia* and its allies are marine animals living at depths of 15 to 800 fathoms on soft muddy ground; they are found crawling on corals and hydrozoa, on which they feed. The British genera are: *Neomenia, Rhopalomenia* and *Myomenia.* They have been taken in nearly all seas except the South Atlantic and S.E. and N.W. Pacific. About forty species are known. *Chaetoderma,* of which nine species have been described, has similar habits and distribution, but feeds chiefly on Porozoa.

The order Aplacophora is divided into two suborders.

**Suborder I. Neomeniomorpha.**—Aplacophora with a distinct longitudinal ventral groove; bisexual with paired genital glands and no distinct duct. The whole of the skin except the ventral groove corresponds to the mantle of *Chiton.* The cuticle, in some species very thick, contains numerous spicules which are long, hollow and calcified; they are secreted by epithelial papillae. In some species there are also sensory papillae comparable to the aesthetes of Chiton. A small longitudinal projection in the ventral groove represents the

*Fig. 9.—Neomenia carinata,* Tullberg (after Tullberg).

A. Lateral view, B. Anterior, C. Ventral view, D. Posterior extremity, E. Dorsal view, F. Narrow foot. In the groove open mucous glands, a large one anteriorly and another opening into a posteriorly cloacal, branchial cavity.

*Branchiae.*—In *Neomeniidae* and most of the *Paramenidae* there is a circle of gills on the inner walls of the cloacal chamber. These gills are simple folds or laminae of the body wall. In other species they are absent.

*Intestine.*—The mouth opens into a muscular pharynx lined by a thick cuticle. Into the pharyngeal cavity open salivary glands and radial sac. The former are paired and ventral, and open on a subradicular prominence. In some species there is a second dorsal pair. *Neomenia* and other genera have no salivary glands.

The radula when present comprises several transverse rows of teeth, and each transverse row may have several teeth (polystichous), two teeth (dichotous), or one tooth (monostichous). It is a curious fact that in the original type *Neomenia* the radula is entirely absent, as it likewise is in several genera of *Premeoniidae.* The oesophagus is short and leads into a long, straight stomach, provided with numerous asymmetrical lateral cavities. The stomach opens into a short straight rectum which opens into the branchial chamber.

*Coelom, Gonads and Excretory Organs.*—The coelom differs from that of the Chitons in the fact that the cavities of the genital organs are connected with the stomach only by one pair of coelomods resembling the renal organs of Chitons, but serving also as genital ducts. The gonads are paired and hermaphroditic; they form a pair of anterior prolongations of the pericardium, extending nearly to the anterior end of the body cavity. On the median, spermatozoa on the outer wall of each genital tube. The pericardium is ciliated internally on its dorsal and lateral walls. The unino-genital tubes arise from the posterior angles of the pericardium, pass first forwards, then backwards, and unite to open by a common opening into the cloaca below the anus except in
The heart and vascular system are similar to those of the Neom- 
omeniomorpha, the only important differences being that the ves- 
icle of origin, in Neomenia, is free in the pericardial cavity, and that the latter is traversed by the retractor muscles of the gills. 
Nervous System.—There are two closely connected cerebral 
ganglia, from which arise the usual two pairs of nerve cords. Pallial and 
branchial nerves are united together in the two groups, and posteriorly they unite into a single cord, and in front of it a 
motorian ganglion (fig. 7, C). A small stomatogastric commissure bearing two small ganglia arises from the cerebral 
ganglia and surrounds the oesophagus.

The development is at present entirely unknown.

General Remarks on the Amphiura. 

The most important theoretical question concerning the 
Amphiurae is how far do they represent the original condition 
of the ancestral mollusc? That is to say, we have to inquire 
which of their structural features is primitive and which modified. 
Their bilateral symmetry is obviously to be regarded as primitive, 
and the nervous system shows an original condition from which 
that of the asymmetrical twisted Gastropods can be derived. 
But in many other features both external and internal the three 
principal divisions differ so much from one another that we must 
consider in the case of each organ-system which condition 
is the more primitive. According to Paul Pelseneer the Poly- 
placophora are the most archaic, the Aplacophora being specialized in (1) the great reduction of the foot, (2) the dis- 
appearance of the shell (Cryptoplas among the Polyplacophora 
showing both reductions in progress), (3) the disappearance 
of the radula. But it is a widely recognized principle of morphology 
that a modified animal is by no means modified to the same degree in all its organs. A form which is primitive on 
the whole may show a more advanced stage of evolution in some 
particular system of organs than another animal which is on the 
whole more highly developed and specialized. Thus the indis- 
putable metameric characters of certain organs in the Chitonians is not 
primitive but acquired within the group, e.g., the shell valves 
and the ctenidia. And although embryology seems to prove 
that the Neomorphomorpha are derived from forms with a 
series of shell-valves, nevertheless it seems probable that the calcareous 
species which alone are present in adult Aplectenid can no longer be 
said to resemble a species of the ancestral mollusc.

It is held by some morphologists that the mollusc body is 
unsegmented, and therefore to be compared to a single segment of 
Chelathopa or Aplacophora. In this case there should be only 
one pair of coelomoducts in the adult, the pair of true nephridia 
which should also occur being represented by the larval nephridia. 
There are also to be only a single coelom, or a pair of lateral 
coelom cavities. On this view then the Aplanocarida are more 
primitive than the Polyplacophora in the relations of coelom, 
gonad and coelomoducts; and the genital ducts of the Chitonians 
have arisen either by metameric repetition within the group, 
or by the gradual loss of an original connexion between the 
pericardial sac and the renal tube, as in Lamellibranchs and 
Gastrophorae, the generative sac acquiring a separate duct and 
opening to the exterior on each side.

CHITRAL, a native state in the North-West Frontier Province of 
India. The state of Chitral (see also Hindu Kush) is some- 
what larger than Wales, and supports a population of about 
35,000, 1,000, hardly hillmen. Previous estimates put the number 
far higher, but as the Mehtar assesses his fighting strength at
CHITTAGONG—

The District of Chittagong is situated at the north-east corner of the province, occupying a strip of coast and hills between the sea and the mountains of Burma. Its area is 2,492 sq. m. In 1901 the population was 1,533,250, showing an increase of 5% in the decade. A few unimportant ranges rise within the north-east corner portion, the highest hill being the sacred Sitakund, 1,155 ft. high. The principal rivers are the Karnaphuli, on which Chittagong town is situated, navigable by sea-going ships as far as Chittagong port, and by large trading vessels for the lower part of the river, and the Kanchi and the Sangu, which are also navigable by large boats. The wild animals are tigers, elephants, rhinoceros, leopards and deer. The climate is comparatively cool, owing to the sea breeze which prevails during the day; but for the same reason, the atmosphere is very moist, with heavy dew and frequent fogs. Chittagong was ceded to the East India Company by Nawab Mir Kasim in 1760. The northern portion of the district is traversed by the Assam-Bengal railway. Tea cultivation is moderately successful.

The Chittagong Hill Tracts formed an independent district from 1860 to 1891, when they were reduced to the status of a sub-division, but were then again created a district in 1900. They occupy the range between Chittagong proper and the south Lushai hills. The area covers 515 sq. m., and in 1901 the population was 124,762, showing an increase of 16% in the decade. The inhabitants, who are either Arakanese or aboriginal tribes, are almost all Buddhists. The headquarters are at Rangamati, which was wrecked by the cyclone of October 1889.

The Division of Chittagong lies at the north-east corner of the Bay of Bengal, extending northward along the left bank of the Meghna. It consists of the districts of Chittagong, the Hill Tracts, and the Chittagong Borough, its area covers 11,773 sq. m.; the population in 1901 was 4,737,731.

CHITTUR, a town of British India, in the North Arcot district of Madras, with a station on the South Indian railway. Pop. (1901) 10,803. Formerly a military cantonment, it is now only the civil headquarters of the district. It has an English church, mission chapel, and Roman Catholic chapel, a high school, and several literary institutes.

CHITTY, SIR JOSEPH WILLIAM (1828-1899), English judge, was born in London. He was the second son of Thomas Chitty (himself son and brother of well-known lawyers), a celebrated special pleader and writer of legal text-books, in whose pupil-room many distinguished lawyers began their legal education. Joseph Chitty was educated at Eton and Balliol, Oxford, gaining a first-class in Literae Humaniores in 1851, and being afterwards elected to a fellowship at Exeter College. His principal distinctions during his school and college career had been earned in his capacity as a student of both English and civil law, and his ability to translate with facility and command the Latin and Greek of Cicero and Xenophon.

The town of Chittagong (pop. 1901, 82,128), is chiefly famous for a siege that it sustained in the spring of 1895. Owing to complications arising from the demarcation of the boundary of Afghanistan which was being carried out at that time, and the ambitious projects of Umar Khan, chief of Jandol, which was a tool in the hands of Sher Afzul, the political refugees from Chittagong supported by the British at Kabul, the mutins of 1895 were put down by the British, and a small British and Sikh garrison subsequently besieged in the fort. A large force of Afghan troops was at that time in the Chittagong river valley to the north-east of the town, and they were finally relieved by the British as their progress of boundary demarcation. It is considered probable that some of them assisted the Chittalis in the siege. The position of the political agent Dr Robertson (afterwards Sir George Robertson) and his associates (of which he was one) was at one time critical. Two forces were organized for the relief. One was under Sir R. Low, with 15,000 men, who advanced by way of the Malakand pass, the Swat river and Dir. The other, which was the first to reach Chittagong, was under Colonel Kelly, commanding the 32nd Pioneers, who was placed in command of all the troops in the Chittagong district, numbering about 600 all told, with two guns, and instructed to advance by the Shandur pass and Mastuj. This force encountered great difficulties owing to the deep snow on the pass (12,250 ft. high), but it easily defeated the Chittalis and 2,000 Afghans, and relieved Chittagong on the 27th of April, the siege having begun on the 4th of March. Sher Afzul, who had joined Umar Khan, surrendered, and eventually Chittagong was restored to British control. During Lord Northwick's Viceroyalty the British troops were concentrated at the extreme northern end of the Chittagong country at Kila Drost and the force was reduced, while the posts vacated and all outlying posts were handed over to local officers. In the late months of 1901 these forces from the Swat were in Chittagong. The town, while the Chittagong Fort (1901) 7,500. Formerly a military cantonment, it is now only the civil headquarters of the district. It has an English church, mission chapel, and Roman Catholic chapel, a high school, and several literary institutes.

It has an English church, mission chapel, and Roman Catholic chapel, a high school, and several literary institutes.

CHITTY, SIR JOSEPH WILLIAM (1828-1899), English judge, was born in London. He was the second son of Thomas Chitty (himself son and brother of well-known lawyers), a celebrated special pleader and writer of legal text-books, in whose pupil-room many distinguished lawyers began their legal education. Joseph Chitty was educated at Eton and Balliol, Oxford, gaining a first-class in Literae Humaniores in 1851, and being afterwards elected to a fellowship at Exeter College. His principal distinctions during his school and college career had been earned in his capacity as a student of both English and civil law, and his ability to translate with facility and command the Latin and Greek of Cicero and Xenophon.
on a hill 1305 ft. above sea-level, and is surrounded by medieval walls, in which, in places, fragments of the Etruscan wall are incorporated. The cathedral of S. Mustiola is a basilica with a nave and two aisles, with eighteen columns of different kinds of marble, from ancient buildings. It has been restored and decorated with frescoes in modern times. The campanile belongs to the 13th century. The place was devastated by malaria in the middle ages, and did not recover until the Chiana valley was drained in the 18th century. For the catacombs see CLUSSUM.

CHIVALRY (O. Fr. chevalerie, from Late Lat. cavalleria), the knightly class of feudal times, possessing its own code of rules, moral and social (see KNIGHTHOOD and CHIVALRY). The primary sense in the middle ages is "knights" or "fully armed and mounted fighting men." Hence the term came to mean that gallantry in battle and high sense of honour in general expected of knights. Thus "to do chivalry" was a medieval phrase for "to act the knight." Lastly, the word came to be used in its present very general sense of "courtesy." In English law chivalry meant the tenure of land by knights' service. It was a service due to the crown, usually forty days' military attendance annually. The Court of Chivalry was a court instituted by Edward III., of which the lord high constable and earl marshal of England were joint-presidents. When held in the common soldiery's jurisdiction as regards all offences committed by knights, and generally as to military matters. When the earl marshal alone presided, it was a court of honour deciding as to precedence, coats of arms, &c. This court sat for the last time in 1737. The heraldic side of its duties are now vested in the earl marshal as head of the Heralds' College.

CHIVASSO, a town and ecclesiastical see of Piedmont, Italy, in the province of Turin, 18 m. N.E. by rail from the town of Turin, 600 ft. above sea-level. Pop. (1901) 4160 (town), 6804 (commune). It is situated on the left bank of the Po, near the influx of the Orco. The cathedral is of the 15th century with a fine façade ornamented with statues in terra-cotta. It was an important fortress in the middle ages, and until 1804, when the French dismantled it. One tower only of the old castle of the marquesses of Monferrato, who possessed the town from 1164 to 1433, remains. Chivasso is on the main line from Turin to Milan, and is the junction of branches for Aosta and Casale Monferrato.

CHIVE (Allium schoenoprasum), a hardy perennial plant, with small narrow bulbs tufted on short root-stocks and long cylindrical hollow leaves. It is found in the north of England and in Cornwall, and growing in rocky pastures throughout temperate and northern Europe and Asiatic Russia, and also in the mountain districts of southern Europe. It is cultivated for the sake of its leaves, which are used in salads and soups as a substitute for young onions. It will grow in any good soil, and is propagated by dividing the roots into small clumps in spring or autumn; these are planted from 8 to 12 in. apart and soon form large tufts. The leaves should be cut frequently so as to obtain them tender and succulent.

CHLOPICKI, GREGORZ JÓZEF (1772-1834), Polish general, was born in March 1772 in Podolia. He was educated at the school of the Basilians at Sarzogrod, from which in 1797 he ran away in order to enlist as a volunteer in the Polish army. He was present at all the engagements in 1793 and 1794, and especially distinguishing himself at the battle of Raszowiec, when he was General Rymkiewicz's adjutant. On the formation of the Italian legion he joined the second battalion as major, and was publicly complimented by General Oudinot for his extraordinary valour at the storming of Peschiera. He also distinguished himself at the battles of Modena, Busano, Casabianca and Ponto. In 1807 he commanded the first Vistulan regiment, and rendered good service at the battles of Eylau and Friedland. In Spain he obtained the legion of honour and the rank of a French baron for his heroism at the battle of Epila and the storming of Saragossa, and in 1809 was promoted to be general of brigade. In 1812 he accompanied the Grande Armée to Russia, was seriously wounded at Smolensk, and on the reconstruction of the Polish army in 1813 was made a general of division. On his return to Poland in 1814, he entered the Russian army with the rank of a general officer, but a personal quarrel with the grand duke Constantine resulted in his retiring into private life. He held aloof at first from the Polish national rising of 1830, but at the general request of his countrymen accepted the dictatorship on the 5th of December 1830; on the 23rd of January 1831, however, he resigned in order to fight as a common soldier. At Wavre (Feb. 19) and at Grochów (Feb. 20) he displayed all his old bravery, but was so seriously wounded at the battle of Olszyna that he had to be conveyed to Cracow, near which city he died in complete retirement till his death in 1854.

CHLORAL, or Trichloracetaldehyde, CCl₃·CHO, a substance discovered by J. von Liebig in 1832 (Ann., 1832, 1, p. 189) and further studied by J. B. A. Dumas and Steadeler. It is a heavy, oily and colourless liquid, of specific gravity 1.541 at 0°C., and boiling-point 97.5° C. It has a greasy, somewhat bitter taste, and gives off a vapour at ordinary temperature which has a pungent odour and an irritating effect on the eyes. The word chloral is derived from the first syllables of chlorin and alcohol, the names of the substances employed for its preparation. Chloral is soluble in alcohol and ether, in less than its own weight of water, and in four times its weight of chloroform; it absorbs chlorine, and dissolves bromine, iodine, phosphorus and sulphur. Chloral deliquesces in the air, and is converted by water into a hydrate, with evolution of heat; it combines with alcohols and mercuric salts. An ammoniacal solution of silver nitrate is precipitated by chloral; and nascent hydrogen converts it into aldehyde. By means of phosphorus pentachloride, chlorin can be substituted for the oxygen of chloral, the body CCl₃·CCl₆H being produced; an analogous compound, CCl₃·(C₆H₅)₂H, is obtained by treating chloral with benzene and sulphuric acid. With an alkali, chloral gives chloroform (q.v.) and a formate; oxidizing agents give trichloracetic, CCl₃·CO·OH. When kept for some days, as also when placed in contact with sulphuric acid or a very small quantity of water, chloral undergoes spontaneous change into the polymere metachloral (CCl₃·CO·OH), a white porcellaneous body, slowly volatile in the air, and converted into chloral without melting at 186°C. Chloral unites directly with hydrocyanic acid to form 5-tribromochloronitrile, CCl₃·CH(CN)CN, and with hydroxylamine it forms chloroglyoxime, C₆H₅ClN₂O₂.

Chloral is prepared by passing dry chlorine into absolute alcohol; the latter must be cooled at first, but afterwards heated to the boiling-point of the absolute alcohol at ordinary diluting. The alcohol is converted finally into a syrupy fluid, from which chloral is procured by treatment with sulphuric acid (see P. Fritsch, Ann., 1864, pp. 279, 288). The crude chloral is distilled over, and is purified by further treatment with sulphuric acid, and by redistillation. A mixture of starch or sugar with manganese peroxide and hydrochloric acid may be employed instead of alcohol and chlorin for the manufacture of chloral (A. Staeedler, Ann. Ch. Pharm., 1847, 61, p. 101). An isomer of chloral, parachloralide, is made by passing excess of dry chlorine into absolute methyl alcohol.

Chloral hydrate, CCl₃·CH(OH)₂, forms b scaff, often very white, rhombic prisms. The crystals are usually transparent, only slightly odorous, free from powder, and dry to the touch, and do not change its white by exposure. The melting-point of pure chloral hydrate is 57°C, the boiling-point 96-98°C. When heated with sulphuric acid, and cooled rapidly, it decomposes into chloral, CCl₃·CHO. When mixed with water, chloral hydrate causes a considerable degree of cold; and, as with camphor, small fragments of it placed on the surface of water exhibit gyrationary movements. Chloral hydrate does not show the slight colour to a solution of fuchsin which has been decolorized by sulphuric acid, and so one must assume that the water present is combined in the molecular condition (V. Meyer, Ber., 1880, 13, p. 2543). Chloral may be estimated by distilling the hydrate with milk of lime and measuring the volume of chlorine produced (C. H. Wood, Pharm. Journ., 31, p. 703), or by hydrolysis with a known volume of standard alkali and back titration with standard acid (V. Meyer, Ber., 1873, 6, p. 600). Chloral hydrate has the property of checking the decomposition of a great number
of albuminous substances, such as milk and meat; and a mixture of it with glycine, according to J. Persone, is suitable for the preservation of anatomical preparations. When heated with concentrated glycine to a temperature of 110° to 230° C., chloral hydrate yields chloroform, CHCl₃, and allyl alcohol, CH₃CH=CH₂.

**Pharmacology and Therapeutics.**—The breaking up of chloral hydrate, in the presence of alkalis, with the production of chloroform and formates, led Liebreich to the conjecture that a similar decomposition might be produced in the body; and he supposed that the drug, in 1838, as an anaesthetic and hypnotic. It is now known, however, that the drug circulates in the blood unchanged, and is excreted in the form of urocholoric acid. The dose is from five to twenty grains or somewhat more, and it is often given in the following form:

10 KC10₃

with solids, and testinal attacks slightly patient's respiratory symptoms, which
hydrates, form hydrate, of the drug, but a large proportion of the grains of chloral hydrate to the fluid drachm. Chloral hydrate must be well diluted when given by the mouth, as otherwise it may cause considerable gastro-intestinal irritation. In large doses chloral hydrate depresses the catechol to the circulatory system, which renders the

patient powerless.

It lowers the temperature.

It is a powerful and safe hypnotic, acting directly on the brain, and producing no preliminary stage of excitement. Very soon—or perhaps twenty minutes—after taking such a dose, the patient feels drowsy, which lasts several hours, and is not distinguishable from natural sleep. When he wakens, it is without disagreeable after-symptoms, but with a feeling of natural refreshment. The pupils are always contracted under its influence, except in large doses. There has also rapidly induced a depression of the anterior horns of grey matter in the spinal cord, and as the symptoms of strychnine poisoning are due to violent stimulation of these areas, chloral hydrate is a valuable antidote for such a poison, which should not be hypodermically injected. Its disadvantages are that it is powerless when there is pain, resembling in this feature nearly all hypnotics except opium (morphine) and hyoscyum. Its action on the gastrointestinal canal and on the respiratory and circulatory systems renders its use inadvisable when disease of these organs is present. Its action is not dangerous, and has been employed with success in cases of tetanus, whooping-cough, urinary incontinence, and strychnine poisoning. In the latter case twenty grains in "normal saline" solution may be directly injected into the subcutaneous vein, but not into the subcutaneous tissues.

**Toxicology.**—In cases of acute poisoning by chloral hydrate, the symptoms may be summarized as those of profound coma. The treatment is to give a stimulant emetic such as mustard; to keep up the respiration by artificial means; to bend the knees so that the patient's morbid sleep by the injection of hot strong coffee into the rectum, and by shouting, flapping with towels, &c.; to use artificial respiration in extreme cases; and to inject strychnine. Strychnine is a valuable antidote for its effects. In this case, too, the action of chloral hydrate, than chloral hydrate is to save life in poisoning by strychnine.

Chronic poisoning by chloral is a most pernicious drug-habit. The vice is easily and very rapidly acquired. The victim is usually exorquated under its influence, except in large doses. There is also attacks of easily induced syncope. There are signs of gastro-intestinal irritation, and a tendency to cutaneous eruptions of an erythematous type. The patient may succumb to a dose only slightly greater than that which kills the ordinary animal. The case is generally fatal, and there being no specific remedy. The patient must be persuaded to put himself under restraint, and the drug must be stopped at once and entirely.

**CHLORATES—CHLORINE**

more easy and regular by mixing the salt with powdered manganese dioxide. The salt finds application in the preparation of chloric acid and chlorates, for photographic purposes, and in medicine. Sodium chlorate, NaClO₃, is prepared by the electrolytic process; by passing chlorine into milk of lime and decomposing the calcium chlorate formed by sodium sulphate; or by the action of chlorine on sodium carbonate at low temperature (not above 35° C.). It is much more soluble in water than the potassium salt.

Potassium chlorate is very valuable in medicine. Given in large doses it causes rapid and characteristic poisoning, with alterations in the blood and rapid degeneration of nearly all the internal organs; but in small doses—5 to 15 grains—it partly undergoes reduction in the blood and tissues, the chlorine being formed and oxygen being supplied to the body-cells in nascent form. Its special uses are in ulceration of the mouth or tongue (ulcerative stomatitis), tonsilis and pharyngitis. For these conditions it is administered in the form of a lozenge, but may also be swallowed in solution, as it is excreted by the saliva and so reaches the diseased surface. Its remarkable efficacy in healing ulcers of the mouth or tongue, for which the specific has been ascribed to a decomposition effectuated by the formation of hydrogen peroxide from these ulcers. This releases chloric acid, which, being an extremely powerful antiseptic, kills the bacteria to which the ulcers are due.

**CHLORINE** (symbol Cl, atomic weight 35.46 (O = 16), a gaseous chemical element of the halogen group, taking its name from the colour, greenish-yellow (Gr. χρωσίς). It was discovered in 1774 by Scheele, who called it dephlogisticated muriatic acid; about 1783, C. L. Berthollet, regarding it as being a compound of hydrochloric acid and oxygen, termed it oxygenized muriatic acid. This view was generally held until about 1810-1811, when Sir H. Davy showed definitely that it was an element, and gave it the name which it now bears.

Chlorine is never found in nature in the uncombined condition, but in combination with the alkal metal it occurs widely distributed in the form of rock-salt (sodium chloride); as sylvine and carnallite, at Stassfurt; and to a smaller extent in various other minerals such as mallockite and horn-mercury. In the form of alkaline chlorides it is found in sea-water and various spring waters, and in the tissues of animals and plants; while, as hydrochloric acid it is found in volcanic gases.

The preparation of chlorine, both on the small scale and commercially, depends on the oxidation of hydrochloric acid; the usual oxidizing agent is manganese dioxide, which, when heated with concentrated hydrochloric acid, forms manganese chloride, water and chlorine:—

\[ \text{MnO}_2 + 4 \text{HCl} = \text{MnCl}_2 + 2\text{H}_2\text{O} + \text{Cl}_2 \]

The manganese dioxide may be replaced by various other substances, such as red lead, lead dioxide, potassium bichromate, and potassium permanganate. Instead of heating hydrochloric acid with manganese dioxide, use is frequently made of a mixture of common salt and manganese dioxide, to which concentrated sulphuric acid is added and the mixture is then heated:—

\[ \text{MnO}_2 + 2\text{NaCl} + 3\text{H}_2\text{SO}_4 = \text{MnSO}_4 + 2\text{NaHSO}_4 + 2\text{H}_2\text{O} + \text{Cl}_2 \]

Chlorine may also be obtained by the action of dilute sulphuric acid on bleaching powder.

Volatile in the enormous quantities of chlorine required for various industrial purposes, many processes have been devised, either for the recovery of the manganese from the crude manganese chloride of the chlorine stirs, so that it can be again utilized, or for the purpose of preparing chlorine without the necessity of using manganese in any form (see ALKALI MANUFACTURE).

Owing to the reduction in the supply of available hydrochloric acid on (account of the increasing use of the "ammonia-soda" process in place of the "leblanc" process for the manufacture of soda) Weldon tried to adapt the former to the production of chlorine or hydrochloric acid. His method consisted in the use of magnesium and a considerable temperature for the recovery of which (in the form of ammonium chloride in the ammonia-soda process), and then by evaporating the magnesium chloride solution and heating the residue in steam, to condense the acid vapours and so obtain hydrochloric acid. One day before him E. Solvay had patented the same process, but neither of them was able to make the method a commercial success. However, in conjunction with Pechinée, of Solières (near
Alais, (France), the Weldon-Pechiney process was worked out. The residual magnesium chloride of the ammonia-soda process is evaporated until it ceases to give off hydrochloric acid, and is then mixed with more magnesium; the magnesium oxychloride is broken into small pieces and heated in a current of air, when it gives up its chlorine, partly or entirely, by the action of the hydrochloric acid, and leaves a residue of magnesium, which can again be utilized for the decomposition of more ammonium chloride (W. Weldon, *Journ. of Soc. of Chem. Industry*, 1884, p. 387). Greater success attended the attempts of the Fund of Barre and Company (T. J. C. S., 1905); and Edgar (ibid., 1908). It was subsequently worked at the works of the French firm of Brunner, and Weber & Co. When this process the ammonium chloride is volatilized in large iron retorts lined with Doulton tiles, and then led into large upright wrought-iron cylinders lined with fire-bricks. These cylinders are filled with piles, made of small, hollow, iron vessels filled with magnesium. The magnesium oxide is heated with the potassium chlorate, using such precautions as are necessary to prevent any formation of hydrochloric acid, which might occur if the magnesium was not perfectly dry. At 300° C. the ammonium chloride is decomposed by the magnesium, with the formation of hydrochloric and ammonia. The material is now heated to 600° C. in a current of hot dry gas, containing no free oxygen (from the carbonating plant being used), and then a current of air at the same temperature is passed through the decomposition tank and the issuing gas contains 18-20% of chlorine. This percentage drops gradually, and when it is reduced to about 3% the temperature of the apparatus is lowered, by the admission of air, to 350° C., and the air stream containing the small percentage of chlorine is led of. It has been found that this material has been treated with ammonium chloride vapour and is ready for the hot air current. With four cylinders the process is continuous (L. Mond, *British Assoc. Reports*, 1896, p. 734).

Manufacture. The production of caustic soda by electrolytic methods, much chlorine has consequently been produced in the same manner (see Alkali Manufacture).

Chlorine is a gas of a greenish-yellow colour, and possesses a characteristic unpleasant and suffocating smell. It can be liquefied at -34° C. under atmospheric pressure, and at -105° C. it solidifies and crystallizes. Its specific heat at constant pressure is 0.115, and at constant volume 0.08731 (A. Strecker, *Wied. Ann.*, 1877, 13, p. 20); and its refractive index 1-00772, whilst in the liquid condition the refractive index is 1-367. The density is 2-485 (air = 1) (Treadwell and Christie, *Zell. anorg. Chem.*, 1905, 47, p. 446). Its critical temperature is 146° C. Liquid and solid chlorine are both yellow in colour. The gas must be collected either by downward displacement, since it is soluble in water and also attacks mercury; or over a saturated salt solution, for it is only slightly soluble. At ordinary temperatures it unites directly with many other elements; thus with hydrogen, combination takes place in direct sunlight: with explosive violence; arsenic, antimony, thin copper foil and phosphorus take fire in an atmosphere of chlorine, forming the corresponding chlorides.

Many compounds containing hydrogen are readily decomposed by the gas; for example, a piece of paper dipped in turpentine inflames in an atmosphere of chlorine, producing hydrochloric acid and a copious deposit of soot; a lighted taper burns in chlorine with a dull smoky flame. The solution of chlorine in water, when freshly prepared, possesses a yellow colour, but on keeping becomes colourless, on account of its decomposition into hydrochloric acid and oxygen. It is on this property that its bleaching and disinfecting power depends (see Bleaching). Water saturated with chlorine at 0° C. deposits crystals of a hydrate Cl₂·8H₂O, which is readily decomposed at a higher temperature into its constituents. Chlorine is readily absorbed by the tube, and heating the end of the tube containing the hydrate, whilst the other limb of the tube was exposed in a freezing mixture, M. Faraday was first able to obtain liquid chlorine.
